THE

NATIONAL ENCYCLOPÆDIA:

A DICTIONARY OF

UNIVERSAL KNOWLEDGE.

GUARDIAN.

GUARDIAN, one who has the care of a person and his property. Guardians are appointed only to infants. The law of England indeed provides guardians for idiots and lunatics, but the rules relating to them will be more conveniently considered under **LUNATIC**. In the Roman system the terms Tutor and Curator correspond in some degree to the English Guardian. [**CURATOR**.]

The usual division of guardians is:—I. Guardians by the common law. II. Guardians by custom. III. Guardians by statute.

I. *Guardians by the Common Law* were of four kinds; guardians in chivalry, in socage, by nature, and for nurture.

1. *Guardianship in Chivalry* is now abolished by the Stat. 12 Car. II. c. 24, which abolished the onerous portions of the feudal system. This guardianship, being considered more an interest in the guardian than a trust for the ward, was saleable, and, if not disposed of, passed at the lord's death to his personal representatives.

2. *Guardian in Socage*.—This also is a consequence of tenure, and takes place only where lands of socage-tenure descend upon an infant under the age of fourteen. Upon attaining that age, the guardianship in socage ends, and the infant may appoint his own guardian. The title to his guardianship is in such of the infant's next of blood as cannot have the estate by descent in respect of which the guardianship arises. The guardian in socage is entitled not only to the custody of the person and socage estates of the infant, but also to his hereditaments not lying in tenure, and even his copyhold estates, where no custom to the contrary exists in the manor of which they are held, and also his personal property. The guardianship in socage is not saleable or transmissible, but on the death of the guardian the wardship devolves on the person next in degree of kindred to the infant, who cannot be his heir, and the guardian is accountable to the infant for the profits of his estate.

3. *Guardian by Nature*.—This species of guardianship has no connection with tenure. It extends only to the custody of the infant's person, and lasts till he attains twenty-one. Any ancestor of the infant may be such a guardian, the first right being in the father, the next in the mother, and, if they be dead, the ancestor to whom the infant is heir has a right to the custody of his person. Until fourteen, it seems the guardian in socage is entitled to the

GUARDIAN.

custody of the person, and after that age the guardian by nature.

4. *Guardians for Nurture* are the father and mother of the infant. Both these last descriptions of guardianship are also superseded by the appointment of a guardian by statute.

Where an infant is without a guardian, the Court of Chancery has power to appoint one; and this jurisdiction seems to have vested in the king, in his Court of Chancery, upon the abolition of the Court of Wards. Where a proper case exists for the jurisdiction of this court, it will interfere not only with the property of the infant, but also with the custody of his person, and will, in case of any misbehaviour, remove a guardian, however he may have been appointed or constituted, and will appoint a proper guardian to the infant in his room. There was an instance of this jurisdiction in the case of the Duke of Beaufort *v.* Wellesley—where Lord Eldon deprived a father of the custody of his children, as not being a fit person to have the charge of them. All courts have power to appoint a guardian to defend a prosecution or suit instituted by or against an infant. (Co. Litt., 88, b. Hargr. note.) Guardians are now appointed by the judges of the Court of Chancery in chambers upon summons.

II. *Guardians by Custom*.—By the custom of the city of London the guardianship of orphans under age and unmarried belongs to the city; and in many manors particular customs exist relating to the guardianship of infants.

III. *Guardians by Statute*.—Guardians by statute are now appointed by virtue of 12 Car. II. c. 24. Under this statute, fathers, whether under age or of full age, may, by deed or will attested by two witnesses, appoint any person or persons guardians of their unmarried children until they attain twenty-one, or for any less period. But by 1 Viet. c. 26, §§ 7, 8, no will made by a person under twenty-one years of age is valid.

A guardian appointed under this statute supercedes all other guardians, except those by the custom of London, or any city or corporate town in favour of which an exception is made, and is entitled to the custody of the infant's person and his property. If two or more persons are appointed guardians under the provisions of this statute, the guardianship remains to the survivor.

The words guardian and warden are of the same signification: indeed they were formerly used indif-

ferently. Thus the Warden of the Cinque Ports was styled Guardian, or in the old French, Gardeyn, and Churchwardens were styled Gardeyns del Eglise.

GUARDS, in military matters a body of men, whose duty it is to secure the army, or any place, from surprise; and for this purpose there are various kinds of guards; as the *main-guard*, *van-guard*, *rear-guard*, *baggage-guard*, *mounted-guard*, &c. But in a special sense the term more immediately applies to the brigade of household troops, whose duty is to protect the person of the sovereign, and who never leave the country unless their services are specially required abroad. Of these, there are three regiments of foot and three of horse guards. Of the one there are the Grenadiers, the Coldstream, and Scots Fusiliers; and of the other, the First and Second Life-guards, and the Royal Horse-guards. Commissions in these regiments cost more than in others; but the pay is higher, and a grade of superior army rank accompanies each regimental commission. Thus a captain in the guards ranks as a lieutenant-colonel in the army, and a lieutenant as captain.

GUARDSHIP is the man-of-war in charge of a port. It is also used as a *dépôt* for naval recruits until they are attached to other vessels. The captain of a guardship is responsible for the safety of all the war-ships laid up out of use in the harbour.

GUARINI, GIOVANNI BATTISTA, was born at Ferrara in 1537, of a family which had produced several distinguished men of letters. After receiving a careful education he was taken into the service of Alfonso II, duke of Ferrara, who sent him on several missions as his ambassador. In 1582 Guarini left the court, and retired to his villa near Rovigo. After four years he was recalled by Alfonso, who appointed him secretary of state; but Guarini soon after resigned again, and passed into the service first of the duke of Savoy, and afterwards of Vincenzo Gonzaga, duke of Mantua. In 1591 he was once more recalled to Ferrara. In 1592, Alfonso having died, Guarini offered his services to Ferdinand de' Medici, grand-duke of Tuscany, by whom they were readily accepted; but having some time after quarrelled with him also, he passed into the court of Francesco Maria, duke of Urbino. Becoming dissatisfied here also, he left the duke of Urbino, and went to Rome, Ferrara, and lastly Venice, where he died in October, 1612. He often complained of the trammels, jealousies, and ingratitude of courts, and yet could not live away from them. Guarini wrote poetry of various kinds: the most celebrated of his compositions is his 'Pastor Fido' (the faithful swain), a pastoral drama. He wrote also a number of madrigals, and other specimens of lyric poetry. His works were collected and published in four vols. 4to., Venice, 1737.

GUASTALLA. [PARMA.]

GUATEMALA. [CENTRAL AMERICA.]

GUATEMALA LA NUEVA, capital of the state of Guatemala, the first of the republics of Central America in population and wealth, is situated in 14° 37' N. lat., 90° 30' W. long., on a plain, which is about 14 miles long, 9 wide, and 4372 feet above the sea-level; it is 120 miles from the Atlantic and 50 from the Pacific. Population about 60,000. It is built with great regularity; the streets are straight, and cross one another at right angles. They are 40 feet wide, and always terminate in some conspicuous

building; are well paved, and slope from each side towards the middle, where a stream of water runs. The houses have only one story, but occupy a great deal of ground, containing within their walls one, two, or even three court-yards, which have a basin full of water in the middle, and are surrounded by a portico of wooden columns, under which is the entrance to the rooms: the roofs are flat. The town is well provided with water brought by an aqueduct from a spring about four miles distant. The most remarkable buildings are round the market-place, which is situated nearly in the centre of the town. On three sides of it are projecting piazzas, which form a covered walk, under which various articles are exposed to sale. On the east side stands the cathedral, a simple but noble building, and near it on one side the palace of the archbishop, and on the other the University. Besides the cathedral there are twenty-four churches, and religious observances are incessant, chiefly attended by women, who throng the churches at matins and vespers. The town is the seat of an archbishop and of the government authorities; it has a mint, university, two colleges, an hospital, barracks, a public library, and several other literary and scientific institutions. Guatemala enjoys a perpetual spring. The thermometer rarely rises above 80°, and still more rarely descends below 60°. Earthquakes are frequent. New Guatemala has a flourishing trade with Vera Cruz, Mexico, &c., in sugar, cotton, coffee, dye-woods, and other native products. The inhabitants are apt in arts and manufactures; they produce muslins, fine cotton yarn, silver articles, artificial flowers, and embroidery, of high excellence.

Guatemala la Antigua (Old Guatemala), which is about 26 miles W.S.W. of the capital, is situated in a wide valley of great fertility, at the western end of which rise the two volcanoes of De Agua and De Fuego, each about 13,000 feet high. The town itself is at an elevation of 5817 feet. After its partial destruction in 1773, and the foundation of New Guatemala, the Spanish government ordered the place to be abandoned. But as a considerable portion of the town had not suffered by the earthquake, people still returned to it, and the population in 1863 was about 20,000. Among the buildings which have not been destroyed is the cathedral, and the town-hall, a magnificent edifice, and a sample of the style in which the place was built. The town has lately made great progress by the introduction of cochineal cultivation. [CENTRAL AMERICA.]

GUAVA. [PSIDIUM.]

GUAYANA. [GUYANA.]

GUAYAQUIL, an important river in Ecuador, South America. It may be said to be the only stream on the western coast of that continent which is navigable for sea-going vessels. It is navigable to Caracol, about 110 miles, and is known in its upper course successively as the Caracol and Babahoyo.

GUAYAQUIL, the capital of the department of Guayaquil, in the republic of Ecuador in South America, is situated in 2° 12' 12" S. lat., 79° 39' 46" W. long., on the river Guayaquil, which is about two miles wide opposite the town, and enters the sea 40 miles below it, near the island of Puna. Population in 1863, 22,000. Vessels of considerable burthen can sail up to the town, as the tide at full

and change rises 24 feet. The town is built on the northern side of the river, on a low ground devoid of drainage; in the rainy season it is very unhealthy, malignant fevers being then (from December to April) very prevalent. The whole town extends about two miles along the river, but its breadth is inconsiderable. The houses have commonly one story, and the framework is made of strong timbers, in order to resist the shocks of earthquakes, which are often experienced here. In the principal street, the Calle de Comercio, however, almost all the houses are two stories high; the ground-floors being divided into small shops, and occupied by artisans of different trades. The town is divided into two parts, the old and the new. The principal buildings are the cathedral, two hospitals, and two colleges; the last of which have faculties of theology, philosophy, and law. None of the public buildings are distinguished by architectural beauty. Several large balzas are constantly employed to bring fresh water down the river from a distant place. There are few spots, even between the tropics, which, for richness and vigour of vegetation, can vie with the wide valley traversed by the river of Guayaquil. The town has the best harbour on the Pacific shores of South America; and European goods, chiefly fine cottons, woollens, silks, liquors, grocery, soap, metals, and flour, are imported in considerable quantities, and sent up the river to Caracol, whence they are carried on the backs of mules to Quito. The exports from Guayaquil, in order of worth, are cocoa, straw-hats, timber, bark, hides, orchilla, tobacco, sarsaparilla, canes, india-rubber, and coffee. The exports and imports are each valued at about 500,000*l.* a year—one-fourth of which is to and from the United Kingdom. [ECUADOR.]

GUBBIO. [ROMAN SCHOOL OF PAINTING.]

GUBEN. [BRANDENBURG.]

GUDGEON, a small fish common in many of the rivers and other running streams of this country, and also in most other parts of Europe. It is generally about five or six inches in length. The upper parts of the head and body are of an olive-brown colour spotted with black, and the under parts are white. The dorsal fin and the tail are brownish, and spotted with a deeper colour.

The gudgeon belongs to the family *Cyprinidae*, and genus *Gobio*, which latter differs chiefly from the genus *Barbus* (the barbels) in having no strong bony ray at the commencement of either the dorsal or anal fins. Like the barbels, the gudgeons have both the dorsal and anal fins short, and are furnished with barboles, or cirri, about the mouth.

GUELDERLAND, or GELDERLAND, a province of the kingdom of Holland, lying between 51° 45' and 52° 32' N. lat., 4° 57' and 6° 47' E. long., is bounded N. by the Zuider-Zee and Overysse, W. by Utrecht and South Holland, S. by North Brabant, and E. by the Prussian Rhein-Provinz. Its area is 1972 square miles, and the population in 1862 was 411,947. The surface is in general level, but not so flat or low as the adjoining maritime provinces, and the climate is healthy; the soil is good and the pasture luxuriant; but there is a considerable quantity of heath and barren land, some of which is planted with firs, pines, and oak. Guelderland is watered by the Rhine, the Waal, the Yssel, the

Maas, and the Leck, besides which rivers there are several canals. It is crossed by the Amsterdam and Arnheim railroad. Wheat, rye, buck-wheat, potatoes, hops, and tobacco are the principal crops. Orchards are very numerous, and the province is altogether the finest in Holland. Portions of it bear the name of the 'Dutch Paradise,' being studded with country seats, parks, and gardens. Some few manufactures are carried on; among these, paper-making and tanning are the principal.

The capital of the province is ARNHEIM.

Nimeguen or Nymegen, the Roman *Noviomagus*, stands on the left bank of the Waal, and has 21,765 inhabitants. It is built on the slope of a hill, and strongly fortified. The town is well built, but the streets are narrow. The quay is separated from the town by a wall. The most remarkable buildings are the town-house and the church of St. Stephen. Some Roman antiquities have been discovered. On an eminence above the town is the fine café and promenade of the Belvedere, from which there is a very interesting prospect. Nimeguen is a large market for cattle and agricultural produce, especially grain. Beer is extensively brewed, Eau de Cologne distilled, and there are factories for spinning and weaving linen, cotton, and silk. It is famous for the treaties of peace concluded here, August 10, 1678, between Spain, France, and Holland; and February 5, 1679, between Spain and France, the emperor of Germany, and Sweden.

Zutphen, at the siege of which in 1591 Sir Philip Sidney fell, is a strongly fortified town on the right bank of the Yssel, and has 13,973 inhabitants. The ramparts are planted with trees, and form a pleasant public walk. The town is well built, and contains several pretty churches, a town-hall, a house of correction, and the S' Gravenhof, or palace of the counts of Gelderland, all of which are stately edifices.

Hardevyk is a port on the Zuider-Zee; the inhabitants, about 5500 in number, carry on the herring-fishery, and have a considerable corn trade. It was at one time a Hanse Town, is fortified after an ancient fashion, and has a good harbour.

Thiel, a fortress on the right bank of the Waal, is a place of some manufacturing industry, and has 6400 inhabitants.

GUELPHIC ORDER, a military order established in 1815, entitled the Royal Hanoverian Guelphic Order.

GUELPHS and Ghibelines, the names of two great political parties which divided Italy and Germany during the middle ages. The words originally were the war-cries of the partisans of Conrad, duke of Franconia, of the Hohenstauffen family, and Henry the Lion, duke of Saxony, the house of Welf, rival candidates for the empire; but in course of time the name of Guelphs was given to all who were disaffected to the emperor, and that of Ghibelines to the supporters of the imperial authority. The names of Guelphs and Ghibelines passed into Italy, and during the reign of Frederick II. it was divided, as it were, into two camps. When the emperors lost their hold upon Italy, the names of Guelph and Ghibeline were used to distinguish the municipal factions, the Ghibelines being for the most part animated by a spirit of aristocracy, the Guelphs professing to be favourers of a popular form of

government. In the fifteenth century the names of Guelphs and Ghibelines had become a mere traditional shadow, and were at length extinguished with the independence of the Italian republics.

GUENONS, the French name of a group of monkeys belonging to the ancient continent and its islands, and of which the type may be considered to be the Green Monkey (*Cercocebus Sabaeus*, Geoffroy) (*Cercopithecus Sabaeus*, Exleben).

The apes and monkeys of the Old World (family *Simiadae*) may be resolved into the following groups or subfamilies:—

Subfamily I.—Tail wanting; arms long; general figure anthropoid; stomach simple; cœcum with a vermiform appendix.—Genera, *Troglodytes*, *Pithecus*, *Hylobates*.

Subfamily II.—Tail long; no cheek pouches; stomach complex; figure slender; laryngeal sacculi; no vermiform appendix. Thumb of forehands short or rudimentary.—Genera, *Semnopithecus*, *Colobus*.

Subfamily III.—Tail variable; cheek pouches; stomach simple; laryngeal sacculi variable; general figure more robust than in the second subfamily, often massive.—Genera, *Cercopithecus*, *Macacus*, *Cynocephalus*.

It is to the genus *Cercopithecus*, including its subgenera, that the term Guenon strictly appertains. The leading characters are as follows:—Muzzle moderately prominent; the facial angle 45° to 50° ; head round; superciliary ridge moderate; molars crowned with acute tubercles; last molar of the lower jaw, except in one subgenus, with only four tubercles; cheek pouches usually ample; laryngeal sac variable; ischiadic callosities moderate; general contour light, but vigorous; limbs muscular; tail long; fur moderate; hair in general annulated. Locality, Africa.

The *Cercopithecæ*, or *Guenons*, are arboreal in their habits; they inhabit wild forests, and associate in large troops, being, as far as is known, all gregarious in their habits. Their actions are full of energy; restlessness, petulance, and inquisitiveness mark their disposition. During infancy they are gentle, but become irascible and malicious with age. Though their form is light, it is muscular and vigorous, and the limbs are well proportioned; hence the Guenons differ very materially from the *Semnopithecæ* [*SEM-NOPITHECUS*], having neither the meagre contour of body, the long slender limbs, nor the depressed face of the latter. The chest is deep, the loins narrow; the tail is long, and acts, though not so decidedly as in the *Semnopithecæ*, as a rudder and balancer in their motions, which are characterized by abruptness, energy, and decision. They express their displeasure by grinning and chattering, and though seldom venturing to make a decided attack, yet, congregated in large numbers in their native woods, they harass intruders with missiles, and are not to be repelled without difficulty. Their diet is almost exclusively frugivorous, and they often commit great havoc in fields of grain adjacent to the wooded parts of the country; and that not only by what they devour on the spot, but also by what they carry away in their cheek pouches, which extend beyond the angle of the lower jaw, and which, when opportunity serves, they cram with food to be eaten at leisure.

The *Cercopithecæ* are numerous, and resolve themselves into several small groups or sets, according to

the mutual alliances of the species: these are respectively represented by the Patas, the Green Monkey, the Talapoin, and the Pogonias. The White-eyed or Sooty Monkeys form a good subgenus. It is characterized by the presence of a fifth tubercle on the last molar of the lower jaw, by the magnitude of the upper middle incisors; and by the hair being destitute of annulation.

As an example of the genus *Cercopithecus*, we may select the Mona, or Varied Monkey (*C. Mona*) of Western Africa (Guinea).

Guenon (*Cercopithecus Mona*).

The specific characters of this elegant Guenon are as follows:—Head of a yellowish olive colour; a black frontal stripe above the eyebrows is surmounted by another of a whitish tint; back chestnut brown; haunches and limbs externally dusky black; tail black, with a white spot on each side of its origin, on the crupper; under parts and inside of the limbs white; whiskers very full, of a yellowish tint, slightly washed with black.

GUERCINO (properly GIOVANNI FRANCESCO BARBIERI) was born in the year 1590, at Cento, a village near Bologna, belonging to the province of Ferrara. He gave very early proof of his talents, by painting the figure of the Virgin on the front of his father's house when he was only ten years of age. He studied under his countrymen Cremonini and Benedetto Gennari. In his first style he followed the manner of Michael Angelo da Caravaggio. His second style, which is the best and most esteemed, was formed on the results of his observation, the study of the Roman, Venetian, and Bolognese schools, by his connection with the most eminent scholars of the Carracci, and the personal friendship of Caravaggio. He established an academy at Cento in 1616, to which numerous disciples resorted. The general applause which the public lavished on the works of Guido induced him to adopt a third style, in which he endeavoured to attain the suavity of manner of that artist. On the whole, his works are inferior. He died at Bologna in 1666, in the seventy-sixth year of his age. His works are at Rome, Parma, Piacenza, Modena, and Reggio, and in most of the museums and cabinets of Europe.

GUERET. [CREUSE.]

GUERRILLAS (Span. *guerra*, 'war'), a body of men who fight in a desultory manner, and more especially applied to those Spanish *guerrilleros* who

took up arms against the French during their invasion of the Peninsula. Hence the general operations of that war were distinguished by the activity and determination of the Spanish guerrillas, who, without discipline, but acting in concert, assembled in bands at a brief notice, and employed themselves in intercepting detachments and convoys as they passed through the mountains. General Mina, who had 3000 of these men under his command, was one of the principal chiefs, and many extraordinary feats are related as having been performed by him. This term was also applied to armed bodies of men during the recent American conflicts, when not embodied in the regular military services.

GUERIN, PIERRE NARCISSE, BARON, a distinguished French painter, born at Paris in 1774, was the pupil of J. B. Regnault. His works are the perfection of manner in imitation of the antique. The first which attracted general attention was—*Marcus Sextus*, having escaped the proscriptions of Sulla, returns, and finds his daughter weeping by the side of her dead mother; exhibited in 1798: in 1802 he exhibited an *Offering to Æsculapius*, and *Hippolytus* accused by *Phædra*, brought before *Theusis*; in 1808, Bonaparte pardoning those who had revolted at Cairo; in 1810, *Pyrrhus* and *Andromache*, and *Cephalus* and *Aurora*; in 1817, *Dido* listening to the story of *Æneas*, *Ægisthus* urging *Clytemnestra* to murder *Agamemnon*, and *St. Geneviève*.

Guerin was appointed a professor in the *Ecole Royale des Beaux-Arts* in 1814; and he was some years director of the French Academy at Rome: he was created Baron after his return from Rome in 1829. He died at Rome, July 16, 1833. He was member of the Institute and of many foreign academies, and chevalier of the *Légion d'Honneur*, and of the order of *St. Michael*. Many of his works are in the Louvre.

GUERNSEY, one of the islands of the English Channel, belonging to England, is situated between 49° 24' and 49° 30' N. lat., and 2° 32' and 2° 47' W. long. The form of the island approximates to that of a right-angled triangle: the sides face the south, east, and north-west, and are respectively about 6½, 6, and 9 miles long. The coast is somewhat difficult of approach, from the number of the rocks and the rapidity of the currents around it. The tides rise to the height of 32 feet. The northern part of the island is a level tract, and the coast for the most part lies low: the southern part is more elevated, but the high ground is intersected by narrow valleys and deep glens, and the coast is lofty and abrupt. Springs and rivulets are plentiful. The island is almost entirely of granitic formation: the rocks are chiefly gneiss, granite, and sienite.

The soil is fertile, but the improvement of the land has been checked in parts by the subdivision of property, under the law which gives to each son an equal share in his father's property. The country people live upon and cultivate their own estates, the largest of which is said not to exceed 200 Guernsey vergées, or about 74½ English acres, and few of them exceed half that size. A man who farms 20 or 30 acres is accounted a large farmer; the holdings commonly vary from 5 to 12 acres; and the subdivision is progressively going on. Agriculture is carefully attended to; and as much as 54 Winchester

bushels of wheat have been raised per acre. The ashes of sea-weed are the manure chiefly used for corn crops. Neither sheep nor horses are carefully reared; but cows are bred in large numbers, and are much valued for the quantity and richness of their milk. The dairy is on all farms of any size the principal object of attention, and the chief source of the farmer's profit. The butter is in high repute. Rents vary from 10s. to 10*l.* an acre. The chief crops are vegetables, wheat and barley, and apples for cider. The climate is moist, but healthy, and so mild that oranges, melons, figs, myrtles, and the Guernsey lily, flourish luxuriantly. In the north are many tracts of heath; and as wood is not plentiful, fences are commonly made of stone or turf. In some parts, however, there is tolerable abundance of wood, and gentlemen's seats are generally shaded by trees. The shores are abundantly supplied with fish.

The only division of Guernsey is into parishes: these are ten in number, and are as follows:—*St. Andrew*, *Câtel*, *Forest*, *St. Martin*, *St. Peter du Bois*, *St. Sampson*, *St. Saviour*, *St. Torval*, *the Vale*, and *St. Peter's Port*. The population at the last census was 29,804, the area being 15,560 acres. The manufactures are of no importance. Granite, from *Sampson* harbour, employs most of the shipping. The principal articles made in the island are soap, candles, cordage, vinegar, and cider. There are several brick-fields and ornamental pottery works. There are also three or four breweries and manufactures of imitation West India cordials. Guernsey is often used as an entrepôt for strong wines by the London houses. Provisions are extremely cheap.

The only town in Guernsey is *St. Peter's Port*, situated on the slope of a hill about the middle of the eastern coast. What is termed *Hauteville* (the upper town), on the slope of the hill, to the south-west of the old town, is the most modern and best built quarter. The appearance of *St. Peter's Port*, on approaching it by sea, is imposing. As the houses rise one above the other, little or nothing is lost to the eye. The streets, however, are narrow, steep, and crooked; and the houses, though substantial, are dusky-looking and old. The government house is a substantial building. Near to it is *Elizabeth College*, a handsome and extensive building, of mixed architecture and monastic appearance, surrounded with spacious ornamental grounds. *St. Peter's church*, a court-house, prison, hospital, three markets, public library, theatre, assembly room, mechanics' institution, savings bank, two joint-stock banks, are among the chief institutions and buildings of the town. *St. Peter's church* is a fine building of the fourteenth century. The harbour, formed by two piers, is small, but sufficient for the trade of the place. The roadstead affords convenient anchorage. The harbour is defended by *Castle Cornet*, and *Fort George*, a regular fortification on the heights, which stands about half a mile south of the town. It is considered to be of great strength, having barracks for 5000 men. The town is the residence of military and civil governors, both appointed by the Crown. The population of the parish and town in 1861 was 16,388.

In trade and commerce Guernsey is far behind Jersey. There is, however, steam communication with Southampton, Weymouth, and London, and

in 1858 telegraphic communication was also established with England.

The exports from the Channel Islands, Guernsey, Jersey, &c., to England were valued in 1863 at 648,508*l.*, but of this amount not more than one-third was the produce of the islands, the greater part being goods from France. The principal articles were butter, 65,819 cwt*s.*, value 300,918*l.*; granite, 143,307 tons, value 85,626*l.*; potatoes, 107,961 cwt*s.*, value 41,794*l.*; cows and calves, 2580 in number, value 40,395*l.*; and eggs, value 28,136*l.* The other articles supplied by the islands are apples, pears, hides, chestnuts, pork, and rags. The imports from the United Kingdom were of much greater importance; the value in 1863 being 1,012,872*l.*, consisting chiefly of the following articles:—

	Quantity.	Value.
Apparel and haberdashery, ...		£311,680
Beer and ale, ...	6,806 b <i>rls.</i>	20,298
Coal, ...	69,379 tons	32,188
Furniture, ...		21,988
Hardware and cutlery, ...	8,741 cwt <i>s.</i>	34,505
Iron, wrought and unwrought, ...	1,569 tons	29,109
Plate, jewellery, and watches, ...		39,789
Woollen manufactures, ...	761,281 yds.	70,833
Foreign produce, provisions, &c., ...		145,096

Guernsey has a political constitution of its own. The island is under a lieutenant-governor, who represents the sovereign in the Assembly of the States, a parliamentary body composed of the bailiff (who is the speaker), and twelve jurats or judges of the royal court; eight rectors, and two constables of each parish; and fifteen deputies from the whole island. These have the power of making laws and imposing taxes. The latter are very moderate, providing an annual revenue of only about 10,000*l.*, and are derived from harbour dues, publicans, and spirit licenses, and other sources.

The chief court of justice in the island is the royal court, which consists of the bailiff and twelve jurats, the former appointed by the Crown, the latter by the islanders. There is an appeal in certain cases to the Queen in council. Norman customs and ancient precedents form the basis of the civil jurisprudence, which is a complex mixture of Norman and English law. The power of the royal court is very extensive and undefined: it has jurisdiction over all the Channel Islands, except Jersey. Pure French is used in judicial and other public proceedings.

The island constitutes a deanery in the diocese of Winchester. There are eight livings and one perpetual curacy. There are eleven churches and three chapels. The incumbents receive only the small tithes, and the livings are very poor. The great tithes are the property of the Crown, and are appropriated to the governor. The glebe-houses are kept in repair at the expense of their respective parishes. The churches are all of great antiquity. Methodists and other dissenters are numerous. An attempt was recently (1865) made to induce the Government to constitute the Channel Islands into a separate diocese, but without success.

Guernsey contains a considerable number of wealthy inhabitants, and there is a greater degree of refinement than in Jersey; but also a greater spirit of exclusiveness, which has excited the notice, and, in some cases, the ridicule of visitors. The best society is, in dress, manner, and language, on

a level with society of the same rank in England. The country people may be divided into three classes: 1, the substantial landowners and farmers; 2, the small proprietors; and 3, the cottagers. The latter often combine many industrial pursuits within their daily range. The natives of the lower order speak the old Norman French. The knowledge of English is very general among the upper and middle classes. The principal place of education is Elizabeth College, at St. Peter's Port. In each of the parishes there is a school with a small endowment; and there are several other schools and benevolent institutions.

In the sixth century Christianity was introduced into the Norman isles by Sampson, archbishop of St. David's, and by St. Magloire or Maglorius. The religion of the island previous to this period was Druidism, and several cromlechs and other supposed relics of that system remain in the northern portion.

The Channel Islands were included in the duchy of Normandy, and are the only relics of that duchy which remain to the English crown. Guernsey was unsuccessfully attacked by the French in the reigns of Edward I. and Edward VI. In the civil war of Charles I., the island sided with the king's party. Protestantism was introduced into the islands in the reigns of Henry VIII. and Edward VI., and made considerable progress. The islanders have ever since been remarkable for their adherence to the faith of the Reformation, but have always shown a leaning rather to the Presbyterian than to the Episcopal discipline.

Dependencies of Guernsey, viz., Alderney, Sark, Herm, and Jethou.—Of Alderney an account is given elsewhere. [ALDERNEY.] *Sark, Serk, or Sarco*, is about seven miles east of Guernsey. It measures about 3 miles by $1\frac{1}{2}$; but it is so contracted near the centre that it may be regarded as consisting of two parts, one of which is called Little Sark, and they are connected by a high and narrow ridge or isthmus called the Coupée. The coast is indented on every side by small bays; and is so girt with cliffs that there is no way of landing on the island but by scrambling up the cliffs or ascending by a tunnel cut through the solid rock in the little harbour of Creux, on the north-east side. Sark is a table-land, and when approached from the sea presents the appearance of an inaccessible wall of rock, from one to two hundred feet high; but it is broken into romantic valleys, watered by little tumbling brooks, diversified with wood, and, wherever possible, under cultivation. Near the west side is the islet of Brechou, about $1\frac{1}{2}$ miles in circumference.

The healthiness of Sark is attested by the fact that, on the average of ten years, the yearly mortality is not quite one in a hundred. The population in 1861 was 583. The land is generally under tillage. The produce consists of wheat, barley, oats, beans, potatoes, parsnips, and mangel-wurzel, of which more is grown than requisite for home consumption. From the indivisibility of property the inclosures are larger than in the neighbouring islands. The total number of acres is 1400. Many sea-fowl and fish are taken round the coasts. The inhabitants manufacture cheese, stockings, gloves, and Guernsey jackets.

The island, in civil, military, and ecclesiastical affairs, is a dependency of Guernsey, but a power of

making local enactments is vested in the lord of the manor and forty copyholders, who form a little parliament that meets three times in the year. The island forms a curacy, to which the Seigneur of Sark presents. There is a church, a Wesleyan chapel, and school.

In the sixth century Sark was uninhabited. In the middle ages it was a nest of pirates, but these having been destroyed by an expedition fitted out by the men of Rye and Winchelsea, the island was again uninhabited till the time of Edward VI. Then it was occupied by the French, but was retaken by some Flemings in the reign of Mary I., Edward's successor. After this it was uninhabited till 1565, when it was settled by a colony sent by Hillary de Carteret, Lord of St. Ouen's in Jersey, under a patent from Queen Elizabeth.

Herm is within two miles and a half of Guernsey; it measures about $1\frac{1}{2}$ miles by half a mile. It is loftiest in its southern part, where the coast is bounded by cliffs; the northern part has a low shore, with sands extending some distance beyond high-water mark. It is rich in corals, sponges, and corallines. The shores afford abundance of sea-weed for manure. The island is composed of gneiss and granite, which last has been quarried in large quantities for the Thames embankment. It has one little harbour. *Herm* attracts conchologists by a beach extending from a half to three-quarters of a mile, composed of small perfect shells and fragments of larger ones, without the least intermixture of sand or pebbles.

Some hundreds of acres of land are under indifferent cultivation. The produce of the island is mostly corn, potatoes, and a few sheep; wild rabbits are abundant. The population of the island in 1861 was 38.

Jethou lies south by west of *Herm*, distance half a mile from it, and two miles and a half from Guernsey: it is less than half a mile long and about a quarter of a mile broad. It is considerably elevated in proportion to its extent, and the sides are precipitous, except at one spot. It is chiefly composed of gneiss, which has been largely used in constructing the harbour of refuge at Alderney. Very little land is under cultivation, the island being principally a rabbit warren. A most valuable and comprehensive work on the Channel Islands, by Professor Ansted, was published in 1862.

GUESCLIN, BERTRAND DU, was born in 1314, at the castle of Motte Broom, near Rennes. He received in the house of his father that military education which was usually given to the nobles of his time, but could never learn to read or write. At the age of seventeen he distinguished himself at a tournament, and soon afterwards fought successfully in many battles and sieges against the English. After the capture of King John of France at the battle of Poitiers, he upheld by his efforts the cause of France against the formidable Black Prince, the son of Edward III. of England, and obtained many advantages over the English, but was at length taken prisoner by Sir John Chandos in 1364. Peace being soon afterwards concluded, Du Guesclin was liberated, and he led a large company of the disbanded military, who had become a scourge to the country by their depredations, to the aid of Henry

de Transtamare, against his brother Peter the Cruel of Spain, but not till they had plundered Avignon, at that time the residence of the pope, and forced him to give them absolution. Supported by this force under Du Guesclin, Peter was driven from his throne, and Henry established in his place. Peter, however, obtained the assistance of the Black Prince, who led a large army to his support, defeated Du Guesclin, took him prisoner, and sent him to Bordeaux. But, it having been hinted to the Black Prince that he kept Du Guesclin prisoner through fear of him, he instantly offered him his liberty on payment of 100 francs ransom; but Du Guesclin refused this, and valued himself at 70,000 gold florins. Being released, Du Guesclin again joined Henry de Transtamare against Peter the Cruel, who was defeated and put to death, and his rival established on the throne of Castile.

In 1369, when war had begun again between France and England, Du Guesclin was very successful, and took many places from the English; but, having at last met with some reverses, he was calumniated to the king, who loudly manifested his discontent. Du Guesclin felt the injury so deeply that he resigned his command, and resolved to go to Spain; but, staying to assist his friend Sancerre in the capture of the castle of Randam, he died during the siege, in 1380.

Du Guesclin is one of the most popular heroes of France, and his life has often been written.

GUIANA. [GUYANA.]

GUICCIARDINI, FRANCESCO, born at Florence, in 1482, of a noble family, distinguished himself early in the study of the law, of which science he was made professor in his native city. In 1512 he was sent by his countrymen as ambassador to Ferdinand of Aragon, and in the following year on a mission to Leo X., who took him into his service, and appointed him governor of Modena, and afterwards of Parma. After the death of Leo, and the short pontificate of Adrian VI., Clement VII. retained Guicciardini in his service, and trusted implicitly to him as his chief adviser, especially on the affairs of Florence. After the surrender of that city to the imperial and papal arms, in 1530, Guicciardini, as the agent of the pope and the Medici, had a considerable share in the changes that took place in the government of the republic, in which a commission of twelve was appointed, called 'the reformers of the state,' of which Guicciardini was by far the most influential. Afterwards, he and the other adherents of the Medici resorted to the old expedient of calling together a parliament.

On the appeal being made to the Emperor Charles V. against the cruelty and licentiousness of the new duke, Alessandro de' Medici, Guicciardini defended his master in an able though sophistical manner, and succeeded in getting the complaint dismissed; he at the same time prevented the duke from yielding to the request of the emperor that he should acknowledge himself his feudatory. When the Duke Alessandro was murdered in January, 1537, Guicciardini by his timely measures prevented a popular explosion, and obtained the appointment of Cosmo de' Medici as governor of the Florentine republic. Here, however, Guicciardini miscalculated. Cosmo soon exchanged his title as governor for that of duke.

Guicciardini resigned his office, and withdrew to Arcetri, where he employed himself in writing the contemporary history of Italy. He died in May, 1540, at the age of fifty-eight.

Of Guicciardini's history the first sixteen books were published in 1561; the other four appeared afterwards, and the whole twenty together were published for the first time at Venice in 1569, 'Istoria d'Italia di Francesco Guicciardini, Gentiluomo Fiorentino, libri xx.' The most complete and correct edition is that by Professor Rosini, of Pisa, 10 vols. 8vo., 1819-20. Guicciardini stands by common consent at the head of the general historians of Italy. In his tone, however, he cannot be called either moral or patriotic.

GUIDES, in military matters, a corps for obtaining intelligence respecting the country through which an army is passing, and for ascertaining the route or position of the enemy. They invariably accompany head-quarters in time of war. They formerly consisted of the country people in the neighbourhood where an army was encamped, or through which it was marching; but of late years the guides have been formed into a regular corps, with proper officers to command them; and often very useful have they proved in military operations.

GUIDO D'AREZZO was born at Arezzo, in Tuscany, towards the end of the tenth century. When young, he entered a Benedictine monastery, and afterwards became a monk of the order. There he first conceived a new method of writing music, and of instructing in the art; and having well digested his plan, he there also carried it into effect, at a school opened by him for the purpose. He went to Rome on the invitation of Pope John XIX., and then visited the abbot of Pomposa, in the duchy of Ferrara, where he wrote his 'Micrologus,' or brief discourse on music, in which most of his inventions are described, as well as his method of instruction. But his doctrine of solmisation, or the use of the syllables *ut, re, mi, &c.*, is explained in a small tract under the title of 'Argumentum novi Cantus inveniendi.' To Guido we are indebted for the invention of the staff, *i.e.*, the lines and spaces in music, for the reformation of the scale, as also of the mode of notation, and for the art of solmisation.

GUIDO RENI (whom we place here as being, like Raphael, more generally known by his Christian name) was born at Bologna in 1574, where he studied painting, first under Denis Calvart, a Flemish artist, and afterwards visited the school of the Carracci. His genius was not equally adapted to all subjects. He preferred and excelled in those in which tenderness, pathos, or devotion predominate; and in these he is distinguished from all other painters. His standard of female beauty was founded on the antique, the Venus de' Medici, and the Daughters of Niobe. Among his most celebrated works were, an altarpiece in the church of St. Philip Neri at Fano, representing Christ delivering the keys to St. Peter; a St. John in the Archiepiscopal Gallery at Milan; the Virgin and Child and St. John, in the Tanaro Palace at Bologna; and the Penitence of St. Peter after denying Christ, with one of the Apostles comforting him, in the Zampieri Palace, one of his most excellent works. Died in 1642, aged sixty-eight.

GUYENNE. [GUYENNE.]

GUIGNES, JOSEPH DE, born in 1721, at Pontoise, studied the Oriental languages under Etienne Fourmont. In 1745 he was nominated Oriental interpreter to the royal library in the place of Fourmont, and in 1752 was chosen a member of the Académie des Belles Lettres. The French Revolution reduced him to great destitution, but he supported his misfortune with perfect equanimity. He died at Paris in 1800.

His 'Histoire Générale des Huns, des Turcs, des Mogols, et des autres Tartares Occidentaux,' Paris, 1756-58, 5 vols. in 4to., is written with great industry, and founded upon Oriental authorities; but the work is considered defective in criticism and style. He was also the author of twenty-eight memoirs, inserted in the collection of the 'Mémoires' of the Académie des Inscriptions, and of some other learned works.

GUILDFORD. [SURREY.]

GUILDHALL, the building in London answering the purpose of a town hall. In it nearly all public business connected with the different offices of the corporation is transacted. Various courts are also held there, such as the courts of Queen's Bench, Common Pleas, Common Council, Aldermen, and a police court, presided over by one of the aldermen. The building was commenced in 1411, and additions were made at different times till the great fire of London in 1666, when the roof was entirely destroyed. The interior was renovated by Sir Christopher Wren, and again in the last century by Dance, who added the present front. During the last few years great improvements have been made, especially with respect to light and ventilation. In 1865-66, the old roof was replaced by a very handsome one of oak, ornamented with Gothic tracery, and the interior of the building thoroughly cleansed and re-embellished—the entire cost amounting to upwards of 30,000*l*.

The building is situated at the end of King Street, Cheapside. The large hall is 153 feet in length, 49 in breadth, and 60 in height, and is capable of containing from 5000 to 6000 persons. In it are placed the giant statues of Gog and Magog, and it is celebrated for the magnificence of the civic entertainments held there.

The Guildhall is the place where the citizens have for many centuries been accustomed to assemble, not only to transact municipal business, but also freely to discuss public grievances, to consider and suggest remedies for great social evils, and to promote the general interests of humanity. Within its walls events of deep public interest and importance have taken place.

GUILDS. [MUNICIPAL CORPORATIONS.]

GUILLEMOTS (*Uria* of Brisson, Temminck, and others), a genus of sea-birds which Linnæus regarded as a section of his genus *Colymbus*, and which Cuvier places in his family of the *Plongeurs* or *Brachyptères*, a family which includes the Grebes (*Colymbus*), the Guillemots (*Uria*), the Auks (*Fratercula*, *Alca*, &c.), and the Penguins (*Aptenodytes*, *Spheniscus*, &c.)

By most modern ornithologists the Guillemots are placed in the family *Alcade* [ALCA; AUK], as a transition link between the Divers (*Colymbus*), and the more typical Auks, and other genera. [PENGUIN.]

The generic characters are as follows:—Bill of

moderate length, straight, strong, compressed, and cultrated; upper mandible slightly arched towards the tip; angle of the lower mandible gently ascending; commissure nearly straight; nostrils basal, lateral, concave, longitudinally cleft, and half covered by a feathered membrane advancing from the forehead and sides of the face; wings short, narrow, and acute; tail of twelve or fourteen feathers, very short; legs situated at the back part of the abdomen; the tibiae concealed within the integuments; tarsi short and compressed; feet of three toes, all directed forwards, and palmated; outer and middle toes of equal length; the inner one much shorter; claws falcate and sharp pointed.

Geographical Distribution and General Habits.—

The Guillemots seem specially framed for existence in the Arctic and even Polar regions, and are seldom comparatively found in the warmer latitudes. In the north they swarm on all the rocks and islets of the chilling seas. In the short but bright summer that gilds some of their northern haunts they make haste to deposit their eggs, sometimes only one, on the bare rock, without wasting the precious days in making a nest. On the naked ledge that overhangs the sea the young Guillemot is hatched, and, as soon as it is able to bear the shock, is conducted or rather tumbles from its hard nursery into the bosom of the ocean, where a plentiful harvest is spread for it. Here the Guillemots are indeed in their element. Plying their way with wings and feet beneath the waves, and even beneath the ice, they make prey of the small fish and crustaceans which form their principal food. Their native rocks or the ice-caverns shelter them from the storm, and it is only when the winter is more than hyperboreally severe that some of these species are driven to a temporary resort to more temperate climates. Their flight is sharp and rapid, though of no long duration, and generally directed just above the surface of the sea. Their eggs, which are reckoned palatable, notwithstanding their fishy diet, have a thick shell, which has a dull appearance.

The species of the restricted genus *Uria*, as given by Prince Lucien Bonaparte, are—1. *Uria Troile*. Locality, Northern Europe and America. 2. *Uria Brunnichii*. Locality, north of Europe, and north-western parts of North America. 3. *Uria Grylle*. Locality, north and central parts of Europe, and North America generally. 4. *Uria Maudtii*, Licht. Locality, north-east of Europe.

All are subject to a double moult, and the summer dress differs in many respects from that of the winter.

Two species only are truly British: the Foolish Guillemot (*Uria Troile*), and the Black Guillemot (*Uria Grylle*). By way of example, we may describe the Foolish Guillemot as a type of the genus.

Description of both sexes (adult) in their Winter Dress.—Summit of the head, space between the eye and the bill, longitudinal band behind the eyes, and all the upper parts, of a velvety black, slightly inclining to ash; all the lower parts and the extremity of the secondaries pure white: white is also found between the band behind the eyes and the back of the nape, and advances towards the occiput, where it forms on each side an open angle. The ashy blackish colour of the lateral part of the neck seems to form

towards the breast, a kind of collar, feebly indicated by bright ash. Bill ashy black; inside of the mouth livid yellow; iris brown; feet and toes yellowish brown; posterior part of the tarsus and membranes black. Length from the bill to the claws rather more than fifteen or sixteen inches. The female is rather less than the male.

Summer or Nuptial Plumage.—Head, region of the eyes, throat, and all the upper part of the neck, of a velvety brown; inside of the mouth bright yellow: the rest of the plumage as in winter. Thus clad, it is the *Colymbus Troile* of Linnæus and Gmelin; *Le Guillemot* of Buffon; *Foolish Guillemot* of Latham.

Foolish Guillemot (*Uria Troile*).

Young of the Year.—Principally distinguished from the old birds in their winter plumage by the comparative shortness of the bill, which is ashy and yellowish at the base; the black of the upper parts is clouded with ash-colour; the stripe or longitudinal band is not distinct, and mingles by means of ashy spots with the white of the sides of the occiput. Ashy brown predominates on the lower parts of the neck, and the white of the lower parts is not so pure; the tarsi and toes are of a livid yellowish hue.

Geographical Distribution.—The Arctic Seas of the Old and the New Worlds; migratory in winter in large companies along the coasts of Norway and Holland; very common at that time along the shores of the Baltic and the maritime coasts of Holland and France; more rarely found 'upon our seas and great lakes of the interior.' (Temminck.) Spitzbergen, Lapmark, and the White and Icy Seas as far as Kamtschatka. Along the whole coast of Hudson's Bay, Labrador, and Newfoundland. (Nuttall.) The great body of the American birds of this species winter in the Bay of Fundy. (Audubon.)

In the British Islands they are numerous (among other localities) in the Orkneys, on the Bass Rock, the Farn or Fern Isles, the cliffs of Scarborough, the Needles and the cliffs of the Isle of Wight, the Goodeve Rocks not far from St. Ives in Cornwall, and the Isle of Priestholme, contiguous to the island of Anglesey, &c.

Habits, Propagation, Food, &c.—The appellation of Foolish Guillemot has been given to this species from its often suffering itself to be taken by the hand or killed on the spot, especially in the breeding

season, rather than quit the cliff it has chosen for its abode. The sea is the favourite resort of these birds when they leave their cliffs, and there they seek their food, consisting principally of small fish, small marine crustaceans, and small bivalves; they dive with the greatest facility. They are with difficulty roused to flight. Early in April and May, or at the end of March, they begin to assemble on their favourite cliffs in Britain, and lay their single unprotected egg on the flat bare ledge of rock. This egg is generally of a pale green, blotched and stained with black and dark brown (umber). Sometimes the egg is white, with or without a few spots. It is a remarkable sight to see these birds, where they abound, sitting upon their eggs on their rocky shelves, often in line, and so close that they nearly touch each other. As soon as the young are capable of migrating, which is in August, or by the end of that month, they are said to disappear from our shores. Mr. Selby, whose observations are always valuable, gives the following interesting account of these birds:— 'Incubation lasts for a month, and when the young are first excluded they are covered with a thick down, of a blackish gray colour above, and white beneath. This gradually gives place to the regular plumage, and in the course of five or six weeks from the time of hatching they are capable of taking to the water. During the time they remain upon the rock the parents supply them plentifully with the young of the herring and herring-sprats, which form the principal food of this and other species belonging to the *Alcedæ*. Upon the Northumbrian coast these Guillemots breed in great numbers on the Fern Islands, a locality that has afforded me ample opportunities of attending to their economy and watching the changes they undergo. They have selected the summits of three fine isolated pillars, or masses of whinstone (trap-rock), that rise upwards of thirty feet above the level of the sea. Upon these the eggs are laid as close as possible, merely allowing room for the birds to sit upon them, which they do in an upright position. The appearance they make in a dense mass is curious, and the interest is increased by the number of kittiwakes (*Larus tridactylus*) which hover around, and which breed in the small side clefts, or on the projecting angles of the rock; and by the nests of two or three crested or green cormorants, which, from the unusual confidence they display in continuing to sit upon their eggs, even when overlooked from the opposite precipice at only a few yards' distance, seem to be well aware of the security of the station they have chosen. The great body of the breeding birds arrive towards the end of March or the beginning of April, at which time most of them have acquired the perfect nuptial plumage.'

GUILLOTINE, an instrument for the infliction of capital punishment, proposed to the National Assembly of France by Joseph Ignace Guillotin, a physician, a native of Saintes, and a member of the Assembly. It was adopted by a decree of 20th March, 1792.

This instrument, under other names, had existed as a means of public execution long before, in Germany, Bohemia, Italy, Scotland, and England. In German this instrument was called der *Planke der Diele* (the plank of wood), and in older language *Falbeil* (the falling hatchet). In Italy it was known by the name of *Mannaia*. Evelyn, in his Memoirs,

vol. i. p. 170, states that he saw a similar instrument at Naples. Pennecuik, in his 'Description of Tweeddale,' pp. 16, 17, speaks of the Regent Morton of Scotland being executed by the *Maiden* at the cross of Edinburgh, as 'art and part' of the murder of Darnley, 'which fatal instrument, at least the pattern thereof, the cruel Regent had brought from abroad to behead the Laird of Pennecuik of that ilk.' In England, what has been since called the Guillotine was used only at Halifax in Yorkshire, as far back as the time of Edward III. It was in 1650 that the last malefactors there suffered by it. Joseph Ignace Guillotin, who revived the use of this instrument in France, is supposed by many to have perished by his own invention. But this is not correct. He died a natural death, May 26, 1814, at the age of 76.

GUIMARAES. [ENTRE-DOURO-E-MINHO.]

GUINEA, an extensive country on the west coast of Africa, between 15° 41' S. to 10° 20' N. lat., and 10° E. and 14° W. long. The coasts are in general low and unhealthy, but very fertile. The principal rivers are, the Niger or Quorra, the Volta, the Coanza, the Zaire or Conga, and Assinie. The south and west coasts are watered by numerous small streams. The country is divided into North and South Guinea. The chief products are indigo, gold-dust, pepper, cotton, and the sugar-cane. In the forests the elephant, the lion, the rhinoceros, and numerous serpents are found. Fetichism is the prevailing superstition. On the south-west coast is the republic of LIBERIA. The mountains in South Guinea are said to contain copper and iron. The country was discovered by the Portuguese in 1487, and they have always retained nominal possession of the southern districts. The countries along the sea-coast are known to European sailors under six names—Sierra Leone, Grain Coast, Ivory Coast, Gold Coast, Slave Coast, and Benin. Referring for other details to ASHANTEES; COAST, GOLD; DAHOMY, LIBERIA, and SIERRA LEONE, we here treat of Grain Coast, Ivory Coast, Slave Coast, and Benin.

The *Grain Coast* extends from the Sierra Leone peninsula (7° N. lat.) to Cape Palmas (4° 30' N. lat.), a distance of somewhat less than 300 miles. The coast is rocky; the interior is a succession of mountain ridges and of valleys; the mountains are mostly wooded, and the valleys wide and fertile, producing rich crops of rice. Cattle, sheep, pigs, goats, poultry, rice, pepper, camwood, and ivory are plentiful. The species of palm, *Elais Guineensis*, is very abundant and furnishes the palm-oil of commerce, extracted from the seed or nut. Thousands of tons of oil are annually sent to the ports of London, Liverpool, and Bristol, for the manufacture of composite candles. The natives of the neighbourhood, called Kroomen, are an industrious race, very expert seamen, and well known to traders from the Gambia to the Equator. The whole country is divided into three kingdoms, namely Cape Mount, with the towns of Coseeaa and Kingston; Sanguin, with its port Bassa [BASSA]; and a negro kingdom near Cape Palma, inhabited by the Settra Croo tribe. The Grain Coast comprises most part of the republic of Liberia. [LIBERIA.]

The *Ivory Coast* occupies the countries between Cape Palmas and Cape Three Points, a distance of nearly 400 miles. It was so called from the tusks of

the African elephant formerly exported from it in large numbers. In this part the high land of the interior does not come close to the beach, but is divided from it by a low tract, about ten or twelve miles wide on an average. This part of Guinea is inhabited by a number of small negro tribes. The English and Dutch had some establishments west of Cape Three Points, but they have been abandoned. Near Cape Palmas is a spacious and secure harbour formed by a reef.

The *Slave Coast* begins on the west at the Rio Volta, which empties itself into the Gulf of Guinea, near the meridian of Greenwich: it extends eastward to the neighbourhood of the river Formosa, or Benin, a distance of more than 400 miles along the sea-shore. The Rio Volta, which comes down from a great distance, is a broad river in the interior, but towards its mouth it divides into several branches, and forms a kind of delta. The shores of this coast are flat and low, and partly rendered inaccessible by sand-banks. They are covered by extensive salt-marshes and numerous lagoons, traversed by several rivers, among which the Lagos is the most considerable. The interior is partly fertile savannahs, and partly forest. It is divided between the kingdoms of Dahomey, Ardrah, and Lagos. Dahomey occupies the western portion, lying contiguous to the country of the Ashantees. Its capital, *Abomey* ($7^{\circ} 12' N.$ lat.), lies in the mountain-region, and is stated to contain 30,000 inhabitants. The town is walled, and has gates. It trades in oil, ivory, and gold; and is the residence of some English missionaries.—*Calmina*, 15 miles S.E. Abomey, has 15,000 inhabitants. *Whydah* is a town on the shore, being the first city in the state for commerce, though only one of the second in population (15,000). The medium of exchange is the cowrie shells. It is situated in $6^{\circ} 17' N.$ lat., and $2^{\circ} 5' E.$ long. The province of Whydah borders on the Gulf of Guinea, in $0^{\circ} 30' N.$ lat., and $2^{\circ} 10' E.$ long. It is highly fertile, and the inhabitants manufacture and dye good cloths, which, with gold-dust, palm-oil, ivory, and slaves, they exchange with American and Portuguese traders for European manufactures and other produce. Many slaves were lately, and some still are, exported from this district. The chief town is Griwhee, about 8 miles inland.

Several small states lie eastward in the basin of the Niger. *Lagos* is a town 160 miles W. of Benin, with a population of 6000. It was captured and destroyed by the British in December, 1851, and proclaimed a British possession in 1861; since which time the slave trade has been abolished. Revenue (1862), 7130*l.*; expenditure, 6510*l.* Imports, 77,933*l.*; exports, 61,932*l.* This town is the principal port for the country called *Yoruba* or *Yarriba*, which extends from lat. 6° to $9^{\circ} N.$, and from long. 2° to $6^{\circ} E.$ Its length is 350 miles; width, 200 miles. The population is estimated at 2,500,000, the area being about 70,000 square miles. The towns in this district are numerous and large, many of them being ten or twelve miles in circumference, and containing thousands of houses. The state is constantly engaged in petty wars and human sacrifice, and the slave trade still exists. The sea-coast supplies palm-oil; the interior is rich in shee-butter and ivory; and is now (1865) covered with cotton

plantations. *Katunga* is an important town on the Niger, with a population of 15,000.

Benin is a maritime state between lat. 4° and $9^{\circ} N.$, and long. 4° and $8^{\circ} E.$, bounded by Dahomey, Yarriba, the Lower Niger, and the Bight of Benin. Area, 50,000 square miles; population, unknown. The country is well watered, and extremely fertile. Principal rivers, the branches of the Niger at its delta. The religion, government, and customs, are similar to those in ASHANTEE and the rest of Guinea. The export trade is in salt, palm-oil, blue coral, jasper, leopard skins, pepper, native-dyed cloths, and slaves. The town of Benin, capital of the kingdom, is in $6^{\circ} 20' N.$ lat., $5^{\circ} 50' E.$ long., at some distance from the right bank of the river Benin. It occupies a large area, but the population is not probably more than 15,000. It is a mart for live stock, yams, cotton, ivory, and European wares. The king's palace is of great extent, including several squares, with ranges of apartments for officers of state, servants, and others, and with long galleries supported by wooden pillars. The traveller Belzoni died in the town in 1823. (*Johnston's Dictionary of Geography*, 1865; *Milner's History of Geography*, 1864; *Consular Reports*, &c.)

GUINEA, NEW. [PAPUA.]

GUINEA. [MONEY.]

GUINEA-FOWL. [POULTRY.]

GUINEA PEPPER, the seeds of two species of *Amomum*, found on the west coast of Africa, within the tropics; the one, *A. Grana-Paradisi*, the other, *A. grandiflorum*. They are powerfully aromatic, stimulant, and cordial, and are used for the same purposes as cardamoms.

GUINEA-PIG (*Cavia Cobaya*, *Restless Cavy*), the well-known Brazilian rodent now domesticated in Europe.

GUINEA WORM (*Filaria*), a genus of nematoid, or thread-like worms, belonging to the class *Entozoa*. They are long, slender, cylindrical, and slightly attenuated at both extremities. The *Filaridæ* inhabit different animals, and various parts of the body. One of the best known is the Guinea worm (*F. medinensis*), which infests the subcutaneous tissues of the natives of hot climates. Having penetrated the skin a painful and often dangerous tumour is raised. Two other species of *Filaria* are parasitic on man; one in the bronchial tubes, the other in the eye. Other forms are found infesting molluscs, insects, fishes, reptiles, birds, and mammals.

GUINES. [PAS-DE-CALAIS.]

GUINGAMP. [CÔTES-DU-NORD.]

GUIPUZCOA. [BASQUE PROVINCES.]

GUISCARD, or WISCARD, R. [SICILIES, TWO.]

GUISCHARD, CARL GOTTLIEB, was born at Magdeburg in 1724, and died in Berlin, May 15, 1775. He became a colonel in the service of Frederick the Great, and distinguished himself in the Seven Years' War, after the end of which he wrote several works on the military art of the ancients, among which are, 'Mémoires Militaires sur les Grecs et les Romains,' and 'Mémoires Historiques et Critiques sur plusieurs Points d'Antiquités Militaires.'

GUISE, or GUYSE, DUKES OF, the title of a branch of the sovereign house of Lorraine, which settled in France at the beginning of the sixteenth

century. Claude of Lorraine, fifth son of René II., duke of Lorraine, and of Philippa of Guelderland, after contesting his father's succession with his elder brother, went to France, where he married Antoinette de Bourbon in 1513. In 1527 Francis I. made him duke of Guise in Picardy, and peer of France. He died in 1550, leaving a numerous family. One of his daughters married James V., king of Scotland, by whom she had Mary Stuart. Claude's eldest son, Francis, born in 1519, succeeded to the title of Duke of Guise. He had been previously made, by Henry II., Duke of Aumale, in 1547, and he married Anna of Este, daughter of the duke of Ferrara, and granddaughter, by her mother René, of Louis XII. Francis of Guise was the most illustrious of his family, both for his military talents and for his humanity and generosity. He fought in the wars against Charles V., and afterwards against Philip II., and took Calais from the English, who had possessed it for more than two centuries. He and his brother Charles, cardinal of Lorraine, had the principal share in the government of France under the reigns of Henry II. and Francis II. The conspiracy of Amboise (as it was called) by the Calvinists and the prince of Condé, was intended to overthrow the power of the Guises; but the duke, having had timely information of it, removed King Francis II. to Amboise, and had himself appointed lieutenant-general of the kingdom, upon which most of the conspirators were arrested and executed. Under Charles IX. the influence of the Guises somewhat declined. The war of religion having broken out in 1562 by the affray at Vassy, where the duke of Guise's servants and attendants killed a number of Calvinists, the duke fought under the Constable of Montmorency at the battle of Dreux. Shortly after he was murdered in his camp before Orleans by Poltrot de Méré, a Calvinist. Francis' eldest son, Henry, succeeded to his father's titles, and became the leader of his party. Less magnanimous and more factious than his father, he mixed deeply in all the intrigues and plots of the League. Henry of Guise was one of the advisers of the St. Barthélémy massacre, and he ordered the murder of Coligny. He excited the fury of the populace against the Calvinists, whom he not only defeated in battle, but hunted down in every part of the kingdom. After the death of Charles IX., he ruled at will over Henry III., and obliged him to break the promises of peace and toleration which he had made to the Calvinists. Henry III., however, and even his mother Catherine de' Medici, became jealous of the ambition and weary of the insolence of the Guises, and the duke was forbidden to appear at the court and at Paris. Upon this he raised the standard of revolt against his sovereign, and defeated him in his own capital on the 12th May, 1588. The king withdrew to Chartres. The states were assembled at Blois on the 16th October, 1588, and the deputies were found to be almost wholly in the interest of the duke of Guise and his brother the cardinal, who were present. The duke demanded to be appointed high-constable and general-in-chief of the kingdom. Henry then resorted to assassination in order to get rid of the Guises. As the duke was entering the royal apartment on December 23, 1588, he was pierced with daggers, and died at thirty-eight years of age. The

cardinal, his brother, was arrested and killed in prison the next day. Their brother, the duke of Mayenne, escaped. Charles, eldest son of Henry of Guise, was arrested at Blois, and confined in the castle of Tours, from which he escaped in 1591. He and his uncle of Mayenne, and his cousin Charles, duke of Aumale, became the leaders of the League against Henry IV. After that king's abjuration, Charles, duke of Guise, submitted to him in 1594, and the duke of Mayenne followed his example next year. Charles was made governor of Provence, but, under the following reign of Louis XIII., Cardinal Richelieu, jealous of his name and influence, obliged him to leave France. He retired to Tuscany, where he died in 1640. His son Henry II., born in 1614, was at first brought up for the church; but after the death of his elder brother he quitted the clerical state, and assumed the title of Duke of Guise. Having conspired against Cardinal Richelieu, he was tried by the Parliament, and condemned *per contumace*, in 1641. In 1647 he placed himself at the head of the revolted Neapolitans, but was taken prisoner by the Spaniards; and, being released in 1652, he returned to Paris, where he died in 1664, leaving no issue. His 'Mémoires' were published after his death. His younger brother, Louis, duke of Joyeuse, left a son, Louis Joseph of Lorraine, duke of Guise, who died in 1671, leaving an infant son, who died in 1675, five years of age. The line of the Guises thus became extinct.

GUITAR, a musical instrument which, in various shapes, may be traced to the remotest periods of antiquity. The word is derived from the Greek *κίθάρα*; and the terms *Cittern* and *Gittern*, used by the old English poets, are but corruptions of the primitive word.

The English and French guitar of the last century was wide and thin in the body, short in the neck, and strung with wire. The modern guitar, which is of the Spanish kind, and differing little from the lute, consists of a body from seventeen to eighteen inches in length, four in depth, and of a neck of about sixteen inches, the latter carrying a finger-board, divided by seventeen frets. It has six strings, three being of silk, covered with silvered wire, and three of catgut. The instrument is much esteemed in Spain and Italy.

The compass of this elegant instrument is from κ below the bass staff to Λ above the treble staff, including all the intermediate tones and semitones. The best and cheapest guitars are made in Germany.

GUJERAT, or **GUZERAT**, a considerable walled town of the Punjab, 72 miles W.N.W. of Lahore, rendered memorable as the scene of the last effort made by the Sikh army against the British forces, under Lord Gough, February 21, 1849, when they were signally defeated, and their territory annexed to the British dominions. In this action the Sikhs lost fifty-three guns, and their army of 60,000 men was entirely broken up and dispersed. [**HINDUSTAN.**]

GULF. [**BAY.**]

GULF-STREAM. [**ATLANTIC OCEAN.**]

GULL. [**LARIDÆ.**]

GULO, the name of a genus belonging to the family *Mustelidæ*, but which Cuvier places within the pale of his *Plantigrade Carnassiers*, though he

acknowledges that the species approach the *Mustelidae* in dentition and habits.

M. F. Cuvier, in the 32nd number of his 'Dents des Mammifères,' says that he might have treated of the *Grison*, the *Tayra* (*Gulo barbatus* of Desmarest), and the *Glutton*, in his preceding article, where he treats of the dentition of the *Putorius* (*Putorius* of G. Cuvier), *Zorille* (*Zorilla*), and *Martes* (*Martens*); for, he remarks, the dental arrangement of the *Grison* and *Tayra* resemble that of *Putorius*, and that of the *Grison* is similar to the formula observed in *Martes*. The first two, he states, have two false molars above and three below, and the last has an additional one in each jaw. For the rest, these animals have nothing in their teeth to distinguish them; that is to say, he continues, they have the same incisors, the same canines, and the same tubercular teeth. They have consequently all a relish for blood, and could not be separated from each other, were it not for the plantigrade feet of the *Grison*, the *Tayra*, and the *Glutton*, an organization which does not, however, change their propensities, and only leads to the modification of the means by which they satisfy their appetites.

Under the genus *Gulo* Desmarest and Cuvier include the *Glutton* of Northern Europe (*Mustela Gulo* of Linnæus), the *Glutton* of America (*Ursus luscus*, Linn.), the *Grison* (*Viverra vittata*, Linn.), and *Taira* or *Galera* (*Mustela barbata*, Linn.), and the *Ratels*. By zoologists the genus *Gulo* is restricted, and contains only two known species, namely, the *Glutton* of Northern Europe, or *Rossomak* of the Russians, and the *Glutton* of North America, the *Wolverene* or *Quickhatch* of the English residents at Hudson's Bay. It is remarkable that while Linnæus placed the latter among the bears, he regarded the former as a different form, and termed it *Mustela Gulo*. Pallas and Gmelin conferred upon it the title of *Ursus Gulo*.

The characters of the genus *Gulo*, as at present restricted, are as follows:—

Incisors, $\frac{6}{6}$; Canines, $\frac{1-1}{1-1}$; Molars, $\frac{5-5}{6-6} = 38$.

There are three false molars above, four below; the carnassière is well developed, and behind it there is a little tuberculous tooth.

The body is rather low on the limbs; the ears are short and rounded; the feet five-toed, with hooked nails; the sole of the hinder feet rests almost completely on the ground; tail moderate, with a fold underneath at its base, in lieu of a pouch. Habits, nocturnal. It is not clearly ascertained that the Old World *Glutton* (*Gulo arcticus*, Desm.) and the American *Glutton* (*Gulo luscus*) are specifically distinct; indeed, most naturalists regard them as mere varieties; the former, however, is darker in colour than the latter, being of a deep chestnut, passing into black on the limbs, with a brown disk on the back.

The American variety is the *Quickhatch* of Catesby and of the English residents at Hudson's Bay, *Wolverene* of Ellis, and *Wolverene* of Pennant.

The *Glutton* inhabits all the countries bordering on the Northern Ocean, both in Europe and Asia. In Norway it is very common in Drontheim. In America it inhabits Canada, the Fur Countries, and the uncultivated portions of the north of the United

States, where it is well known in consequence of the depredations it commits. It is a fierce and voracious animal, but by no means formidable to man or the larger beasts, though its strength is very great in proportion to its size. Slow in its movements, it makes

Wolverene (*Gulo luscus*).

up by perseverance and industry for this defect, and at a steady pace pursues its prey for miles, hunts out weak or dying animals, robs the hunter's traps of their booty, and destroys hares, marmots, and birds, which it seizes unawares.

GUM is a proximate principle of vegetables, of more universal occurrence than any other secretion by plants. It is the material generally prepared by them for their own nourishment, and is at first in a state of solution; but when it escapes to the exterior of the bark it frequently becomes thickened, and even solid and pulverizable.

The purest gum (arabic) consists of a principle termed *arabin*, and is soluble in water, forming with it a mucilage. Other gums contain *bassorine*, either alone, or with *arabin* and other matters. Gum-arabic, according to Gay-Lussac and Thénard, consists, in 100 parts, of C 42.23, H 6.93, O 50.84. The term gum is sometimes erroneously applied to gum-resins, such as *assaftetida*, &c.

Most of the commercial gums are obtained by incisions made in the bark of several species of acacia growing in Arabia, India, Upper Egypt, Senegal, &c. The specimens differ considerably in colour, even when obtained from the same species. Genuine gum-arabic occurs in pieces from the size of a pea to that of a walnut, or larger, which are irregular in shape, or roundish or angular; either white, yellowish, or dark wine-yellow; scarcely any odour; taste mawkish, glutinous. Gum, when in powder, is often adulterated with starch, the presence of which is detected by tincture of iodine; or, when cold water is used for the solution of the gum, the starch will remain undissolved. The mucilage made with cold water is not only purer, but keeps better, and for all purposes for which it can be used is preferable to that made with warm water, which is the common method.

Gum is highly nutritive, six ounces in twenty-four hours being deemed sufficient to sustain the life of an adult; yet it is not very easily digested when taken alone, and will often pass through the stomach nearly unchanged, if not associated with some bitter or astringent principle. This property, however, renders it demulcent in affections both of the throat

and also of the intestines, by sheathing the membrane from air or the irritation of acrid secretions. Hence allowing a portion to dissolve slowly is often useful in common colds. Mucilage is also used to suspend many insoluble matters in water. Its agglutinating properties render it valuable in many of the arts.

There is no duty on the importation of gum. The following table shows the amount and value of each sort imported into the United Kingdom in the year 1863:—

GUMS.	Quantity. cwts.	Value. £
Animi, ...	4,035 ...	31,946
Arabic, ...	70,903 ...	166,114
Benzoin, ...	3,342 ...	29,615
Copal, ...	8,073 ...	37,606
Dammar, ...	3,291 ...	7,696
Dragon's blood, ...	422 ...	2,492
Euphorbium, ...	68 ...	61
Gedda, ...	6,983 ...	9,550
Lac-dye, ...	11,194 ...	52,851
Lac-seedlac, ...	1,117 ...	5,564
Lac-sticklac, ...	6,553 ...	22,940
Lac-shellac, ...	35,138 ...	268,967
Mastic, ...	228 ...	6,514
Sandarach, ...	2,524 ...	11,857
Senegal, ...	3,007 ...	9,159
Tragacanth, ...	1,008 ...	9,776
Unenumerated, all } other sorts, }	23,311 ...	41,753
Total, ...	181,197 ...	714,461

British India, the northern, eastern, and western coasts of Africa, Portugal, and Holland supply most of the gum for the English market. A considerable quantity is exported to the non-producing countries, the following being the returns for 1863:—

GUMS.	cwts.	£
Animi and copal, ...	9,275 ...	48,267
Arabic, ...	20,140 ...	47,161
Shellac, ...	23,395 ...	179,069
All other sorts, ...	43,971 ...	144,237
Total, ...	96,781 ...	418,734

GUM-BOIL, a very painful form of abscess near the root of a tooth, usually superficial, but sometimes more deeply seated in connection with the bone, and causing considerable swelling, with risk of caries and necrosis. At first it will generally be found sufficient to protect a gum-boil against cold and external injury; but when matter appears, it is generally a good plan to withdraw it by means of a pretty free incision.

GUM-DRAGON TREE, the *Dracena draco* of the botanists, is a plant of gigantic growth, and so called from the astringent resin (dragon's blood) which it yields. Its native island is Teneriffe; and tradition relates that this tree was venerated, from the remotest antiquity, by the aborigines of the island. Humboldt mentions the 'gigantic tree of Oratava,' as measuring forty-five feet in circumference a little above the ground, and that in 1400 it was as large and hollow as it is at the present time.

GUM-RESINS are secretions of plants, which are produced in the greatest quantity, and most perfectly

elaborated, in warm countries. They are obtained chiefly from trees and shrubs of particular tribes of plants, rarely from herbaceous plants, except the large herbaceous umbellifera, which yield the fetid gum-resins. They either exude spontaneously, or are procured by incisions of the stem and branches. When they first escape to the surface they are fluid, and of a light colour, but gradually harden, and become of a deeper hue, either by the evaporation of some of their volatile oil, or by the absorption of oxygen from the air, and the conversion of the oil into a resin. Some remain in a semi-liquid viscid state, such as sagapenum and galbanum, which are only pulverizable in winter. Most gum-resins possess a strong odour, which in many instances is disagreeable, such as that of assafetida, with a warm acrid taste, and by application to the skin for any considerable time they cause redness and inflammation.

Gum-resins are with difficulty soluble in the animal juices; yet, as they must be assimilated before they produce their characteristic effects, they require to be used for some time before the secretions of the body acquire their peculiar odour. They influence the secretory and excretory processes, which they rouse to continued action. They also act upon the skin as sudorifics, and more permanently than the volatile oils. They possess considerable antispasmodic powers, and hence are much used in nervous complaints. They greatly promote digestion when the stomach is feeble, owing to a defective supply of nervous energy. Their utility in the treatment of hysterical and other paroxysms is very much increased by administering them in a state which admits of ready solution in the gastric fluids; hence the acetous preparations of them are much more potent than any other form. They may be administered either by the mouth, or, in case of spasm closing the teeth, or the patient being refractory, in the form of elyster, the dose being doubled in the latter instance.

Gum-resins are likewise applied externally, owing to their rubefacient powers, in the form of liniments or plasters, in spasmodic and rheumatic affections, and also to assist in dispersing indolent tumours.

Gum-resins should be kept in cool well-closed places, to prevent the evaporation of their volatile principles.

Besides the different kinds of gum-arabic and gum-resins already noticed, there are various species, which, as being of great use in medicine and the arts, and forming important articles of commerce, may be here alphabetically enumerated:—

Gum-ammoniacum, an exudation from the bark of the Dorema Ammoniacum of Persia; *Gum-anime*, the resinous production of the Locust-tree in the West Indies; *Gum-benjamin*, a fragrant resin obtained from the bark of the *Styrax benzoin*, of Sumatra, and a principal ingredient in the tincture called Friar's Balsam; *Gum-copal*, the exudation of the *Elaphrium excelsum* of Mexico; *Gum-cystus*, the produce of the genus *Cistus*, or Rock-rose, of the natural order *Cistaceae*; *Dragon's blood*, a red-coloured resinous exudation obtained from the bark of the *Calamus rotang*, a native of the East Indies; *Gum-elastic*, or Caoutchouc, which is the milky juice of the *Jatropa elastica*, of the *Urceola elastica*, and other tropical plants; *Gum-elemi*, or Amyris taxandra, a native of the island of Nevis, from which

is produced a fragrant-resinous juice; *Gum-galbanum*, the secretion of *Galbanum officinale* of Syria; *Gum-guacum*, dark-coloured resinous gum extracted from a tree, the *Guaiacum officinale*, or *Lignum vitæ*, a native of the West India Islands; *Gum-juniper* (or *Gum-sandarach*), a resinous exudation from the *Juniperus communis*; *Gum-lac*, the produce of the *Butea frondosa*, of the West Indies; *Gum-mastic*, extracted from the *Pistacius lentiscus*, of the island of Chios, and used as a stiff varnish; *Gum-senegal*, an exudation of the *Acacia-senegal*, which is sold as gum arabic; *Gum-storax*, a fragrant gum-resin, extracted from the *Styrax officinale*, and used by perfumers to give to spirits of wine a jessamine-like smell; *Gum-tragacanth*, the production of the *Astragalus tragacantha*—with several others noticed under their respective heads.

GUM-TREE. This tree has been described, by Mr. Buckland, as obtaining an immense size, and forming one of the great wonders of vegetable creation. In Australia it is called *Stringy Bark*; and is, as he says, 'the most gigantic tree of Van Diemen's Land. Some of the specimens exceed 200 feet, rising almost to the height of the Monument in London, before branching. Their trunks also will bear comparison with that stately column both for circumference and straightness. One of them was found to measure 55½ feet round its trunk at five feet from the ground; its height was computed at 250 feet, and its circumference was 70 feet at the base.' [EUCALYPTUS.]

GUMBINNEN. [KÖNIGSBERG.]

GUMS. [DENTITION, DISEASES OF.]

GUN. This general name comprehends under it **ARMS, ARTILLERY, and CANNON**, and may be applied to tubular vessels of all forms that are used in the propulsion of shot, shell, or bullets to a greater or less distance by the action of gunpowder exploded within them. The present article relates to the improvements that have recently been made in small arms, such as rifles, pistols, and fowling-pieces. It has been long understood that the most effective method of increasing the military resources of a country open to the gunsmith, was to increase the accuracy and the range of fire-arms. The essential properties of a gun are to confine the gases liberated on the explosion of the gunpowder as completely as possible, and to direct the motion of the bullet in a rectilinear path; hence arises the necessity of an accurate bore for the gun barrel. The advantage of a rifle barrel is principally derived from the more perfect contact of the bullet with its cavity; it is also supposed to produce a rotation round an axis in the direction of its motion, which renders it less liable to deviations from its path, on account of irregularities in the resistance of the air. The old regulation musket, facetiously called 'Brown Bess,' failed to answer the ends of a good fire-arm; and in 1851 it was beginning to be discarded for the Minié rifle. The peculiarity of this latter weapon lay more in the form of the bullet than in the character of the barrel, as shall be presently explained. The old rifle barrel had seven indentations inside, running up in a spiral form. A spherical bullet just a little larger than the bore was driven into the barrel by blows from a hammer, so that it fitted very accurately, and when fired it followed the direction of the rifle barrel,

twisting along with its spiral axis, and leaving the muzzle when discharged with a decided rotation on its own axis. Mr. Jovell, director of the Royal Manufactory at Enfield, suggested a form of rifle barrel and of ball, the former having only two spiral grooves, with the ball accurately fitting to them, so as to slide in as easily as the ordinary musket ball. Experiments made with this rifle showed that it produced more effect than the old musket at double the distance, and that it could be loaded with greater ease and speed. The invention of M. Delvigne was esteemed a further improvement. In his rifle, the ball, which falls freely down into the barrel, rests at the end of a chamber wrought in the breech, and a single stroke of an iron ramrod makes it change its dimensions when it has got there, so as accurately to fill the whole surrounding space of the grooves and barrel. The perfect certainty of effect which this gives is very remarkable. The *Chasseurs de Vincennes* can with this rifle aim with accuracy at a distance of 600 or 700 yards. In rifles, the regular movement along the grooves gives a perfectly regular motion of rotation round the axis, which, like all motions of rotation, destroys and renders insensible whatever lesser irregularities might exist. It will have been noticed that in order to this the ball had to be crushed, so that a considerable part of the force of impulse was spent in undoing this. Hence there is a limit in the Delvigne rifle to its capacity as a weapon. It was besides found inconvenient in cleaning, as the chamber gets foul; and the operation of loading is also fatiguing after a few rounds. M. Minié removed these objections by making his bullet conical in form, and cavitous at its lower end; the lead of this hollow space was, by the explosion, forced into the grooves of the rifle with great diminution of the windage, and a consequent increased accuracy of aim of the rifle takes place as before. In experiments made in 1850 with the Minié bullet, the hollow part was sometimes entirely separated or blown off from the conical part, and occasionally driven violently into some part of the barrel. The more careful construction of the bullet entirely prevents this, as in the case of the regulation Minié bullet used in the British service. It was in 1852 that the British government completely adopted the French invention of expanding bullets for rifles, and in the following year the present Enfield rifle was designed, and in a few years more smooth bores in all branches of the service were totally superseded by arms on the rifle principle. The Enfield now in use is stronger than those first introduced in 1851. It is rifled with grooves on the old system, with one turn in 6 feet 6 inches. Its diameter is .577 of an inch, and at a limited range it fires a bullet weighing 530 grains with great force and accuracy. During the fourteen years that have elapsed since its adoption, the Enfield has proved its efficiency in many battle-fields. Defects, however, still exist, and these were made manifest by the disqualifying comparison this fire-arm was made to present to the later improvements of Mr. Whitworth. The sum of the objections to the Enfield rifle was, that the velocity of the ball proved to be lower than had been looked for, its trajectory was consequently higher and its precision and penetration less; the tendency to foul was considerable, and there was a want of

uniformity in the properties and performances of the weapons compared among themselves. Whitworth's improvements consisted primarily in more perfect workmanship than that expended on the Enfield. He introduced a better system of rifling; a turn in the spiral four times greater than in the Enfield; a bore in diameter one-fifth less, being a reduction from '557 to '451 of an inch, and an elongated projectile capable of an exact mechanical fit.

As cognate to the same general subject, are the methods of rifling guns that have been recently devised. The old rifling tool of gunmakers for small arms consisted mainly of a square rod twisted to the same extent as the grooves were intended to have in the barrel. This rod carried a suitably formed cutter at one end, and was made to slide through a square hole in the centre of a plate with a divided circumference. The divisions of the latter determined the number of grooves round the whole interior of the barrel and the spaces between, and the form of the grooves were fixed by it and that of the cutter; the twist, as has been said, being that of the bar. A rifling machine, invented by F. J. Manceaux, a gunmaker of Paris, and patented in England in 1852, contains the germs of much that has since been achieved in this path. The rifling machine of Mr. Lancaster, and that designed and subsequently improved by Mr. J. Anderson, C.E., superintendent of the Royal Gun Factories, Woolwich, are examples of British invention in the same department of machine construction. Whitworth's cannon are bored cylindrical, and then rifled to a hexagonal form.

Whitworth also invented an important auxiliary to rifle practice, the 'Patent Machine Rest' (see Plate 'Gun,' figs. 1 and 2), by which the mean deviation of the rifle is accurately tested. The process of trial embraces the determination of the angle of deviation at each distance, the amount of deflection, due to the wind and other causes, the effects on the trajectory of different quantities and qualities of powder; and, in fact, all the elements necessary for reducing the manufacture of rifles to a certainty, are by the aid of this apparatus most readily obtained. It is true that the shooting of a rifle so confined differs from its performance when it is discharged from the shoulder, but still much valuable information may be derived from the use of this machine. Figs. 1 and 2 represent a side elevation of the rest and the plan of the bed. The frame, which is stiffened by tension bars, carries a narrow table, on which the gun metal bed or slide is mounted with adjusting screws, so as to be capable of adjustment both in the angle of elevation and in the horizontal plane, to compensate for the fall of the bullet and its deviation from the action of the wind. The rifle is mounted in a light steel cradle, which slides steadily on the bed, and which is removed with the gun from the bed each time it is loaded. A clinometer attached to a steel bar, which fits down the bore of the rifle, gives the true angle of elevation, and serves to detect any accidental change of position.

Besides Whitworth, the names of Needham, Lancaster, Rigby, Adams, Henry, Ingram, Baker, Dougall, Erskine, Dawe, and many others, British and foreigners, should be enumerated as among the distinguished improvers of small arms during these years.

Great attention, also, has been given by recent inventions to the mode of placing the charge in the gun barrel with a view to expedite firing. Although the method of introducing the charge through the muzzle recommends itself by its simplicity and the strength of construction it permits in the breech, still many and important reasons have caused experimentalists, from the earliest invention of fire-arms, to attempt some arrangement which would permit the opposite course, namely, the rapid removal of the breech and introduction of the charge through the opening so made, and its effective closure. Many obstacles combine to render this difficult; the force which we can apply is small; the time necessarily short; the forces operating during the explosion tending to displace the breech very great; the expansion of the metal by the heat evolved in firing is considerable; the passage of a jet of flame (no matter how minute) through the joint is most destructive, as the effect is that of a blow-pipe flame of great intensity; the hard deposit left after the explosion of the charge impedes and deranges the mechanism; and other causes might be added which combine to render breech-loading a practical problem hard to solve satisfactorily. Two distinct systems have been pursued in modern efforts (and it must be remembered that *successful* breech-loading does not date back more than twenty years, although experiments extend over centuries), namely, one in which the joint of the breech and barrels is rendered so close by some arrangement of the parts as to prevent the escape of the imprisoned gases, and another in which a separate case or cartridge which contains the charge is used, which, by its expansion at the moment of ignition, intercepts effectively the escape of the gas through the joint. The latter method has been most successfully developed by the French, the former by the English, in arms designed for military purposes. (See Plate 'Gun.') Figs. 3, 4, 6, and 7 show breech-loaders, the last being 'Dougall's Patent,' styled by the inventor the 'lockfast.' The barrels are secured to the breech-piece, and disengaged therefrom, by the action of an eccentric. The breech-piece and the solid piece attached to the barrels are shown in fig. 3.

Needle Guns.—Figs. 4 and 5 are views of the operative parts of one variety of these guns, known as Needham's patent. Fig. 4 is a side view of this gun with the breech closed. Fig. 5 is a view of the barrels separated from the stock, one action or breech being represented open, and the other closed. The action which contains the lock mechanism consists of two parts which screw into one another: one of these is hung on a cross axis in the rear of the recess; the other is fitted with a finger-piece, which, when the breech is closed, lies close by the side of the stock. To open the breech, the forefinger is applied to this, which, when the breech is closed, lies close by the side of the stock. By means of the finger-piece, the cap is then turned round about a third of a revolution. This movement retracts the needle, i.e., cocks the lock, and at the same time withdraws the nose of the action or breech-piece from the barrel sufficiently to permit the whole mechanism to be thrown into a position at right angles with the bore, as in fig. 5. The charge can thus be introduced, and the breech-piece replaced. The needle

is held back by a catch, which is released by the action of the trigger, and a strong spring then darts into the rear of the cartridge. On opening the breech to reload, a cam in the action pushes back the needle, and so cocks the lock for the next shot.

Rigby's needle-gun, fig. 6, deserve notice because of the ingenious way in which the difficulty of withdrawing the exploded cartridge case is solved. The barrel is hinged to the breech-piece, and held in its place by a peculiar contrivance. In the breech-piece, and opposite the bore of the barrel, a hole is bored and tapped with a four-threaded screw of rapid pitch. A screwed plug fits in this hole, and has a nose which enters the breech end of the barrel for about $\frac{3}{4}$ of an inch. Close alongside the gun, and attached to this plug, is a lever or handle, by means of which the plug can be screwed back and the barrel released. Fig. 7 represents Adam's breech-loader, showing the method of attaching the barrels to the breech-piece. Underneath a steel T-piece, attached to the barrels, and in the centre of the breech-piece, is a lever hung on a cross-pin, the longer end of which projects downward, and is bent to lie around the trigger-guard.

Revolving Pistols.—Those by Adams, shown in fig. 8, are well known. Most pistols of this kind, of the more valued varieties, are provided with a double action, so that they can either be cocked by the thumb, before taking aim, or fired by repeated pulls of the trigger only. Fire-arms of this kind, since their introduction in 1851 by Colonel Colt, have undergone great improvements.

Fig. 9 represents an air-gun, showing the air chamber in the stock, with a condensing syringe, which screws on to that part when the latter is to be charged, by the operation of a T-headed piston acting in the cylinder of the syringe. There is a valve, opening inwards, in the air chamber, and as the piston is driven home, the charge of air it carries before it opens the valve, which again closes all the more closely as repeated charges are sent into the chamber.

Fowling Pieces.—Here, as in the case of the rifle, the most essential part is the barrel, the interior of which is usually a smooth cylinder, but the exterior is made slightly conical by thickening the metal at the breech or under end. The commoner barrels are formed of tenacious soft iron, which is rolled into the form of flat bars, called *skelps*, each of which is sufficient to form a single barrel. The length of a skelp is usually about three feet, and the breadth about four inches at one end, and two and a half at the other. This laborious process of welding is now to a great extent superseded by improved methods. In one of these methods, the barrels, instead of being formed of skelps forged to the length of the barrel, are made from slabs of refined bar-iron, ten or twelve inches long, and weighing from ten to eleven pounds. [GUN-BARREL ROLLING-MILL.] *Twisted* barrels are made of long and very narrow strips of iron; one of which, being moderately heated to increase its pliancy, is wrapped spirally round a cylindrical mandril, in such a way as to form a tube, which may be slipped off the mandril at pleasure. *Damascus* barrels are composed of similar metal, but the rods are twisted upon their own axes until their component fibres have from twelve to fourteen turns in an inch, and the rods are

thereby doubled in thickness and proportionately reduced in length. Most barrels are now *bronzed* by the application of some chemical liquid aided by heat.

The wooden *stock* upon which the barrel is mounted is most commonly made of walnut-tree. When the shaping of the stock is completed, it is shod with brass, the trigger-guard and other metallic fittings and ornaments are let into the wood, and every part is fitted with suitable screws and fastenings, after which the whole is taken to pieces; the woodwork is finished by staining and polishing, the brasswork is filed and polished, and the barrels are sent to be finished, which is done in various ways. Sporting guns are often made with two barrels fixed side by side upon one stock. Such barrels are made separately, and have their adjacent sides filed flat, in order that they may lie close together. They are secured together by ribs running between them from end to end.

GUN-BARREL ROLLING-MILL. The use of machinery for rolling gun-barrels has been of great advantage in this branch of mechanical art. The process has been made both much cheaper and speedier than before. If the reader will turn to the Plate with this title, he will find a good illustration of one of the best machines in use for this purpose. It was designed and constructed by Mr. Joseph Taylor, of the Derwent Iron Works, Birmingham, for the Colt's Small Arms Company, Hartford, United States, and supplied by him soon after the breaking out of the recent war. Fig. 1 is a side elevation of the rolling mill and its driving gear, and in vertical section through the foundation. Fig. 2 is a transverse vertical section of the large set of rollers for the final welding and shaping of the gun-barrels. The principal part of the mill only, which is shown in the engraving, comprised three pairs of rolls for bending the 'skelps,' and three pairs for welding the barrels and rolling them out into the proper form, with one furnace to each set of rolls; and similar machinery has been supplied to the government Small Arms Manufactory, at Enfield, Middlesex. He also sent out, in 1862, to the American Government eleven sets of these rolls for the rolling mills at Harper's Ferry, and Springfield, U.S., to replace some Mr. Taylor had supplied a few years before, which, it will be remembered, were taken possession of by the Confederates when they entered Harper's Ferry; and this valuable prize was removed by them to Richmond, where the mill was employed rolling gun-barrels night and day, until that place was taken possession of by the troops of General Grant. Fig. 3 represents an end view of a piece of iron technically called a 'skelp,' from which the barrel is to be formed. Fig. 4 represents the form it receives after being heated in the furnace, and passed through the first aperture in the bending rolls. Figs. 5, 6, 7, and 8, represent the form it takes during its progressive passage through the bending rolls, A. The 'skelp' is now in the form required for 'welding up,' for which purpose it is put in the furnace, and when in a thorough welding state, is taken out on a mandrel, *a*, and being applied to the largest, or 'welding grooves' of the rollers marked B, is instantaneously caught and forced through the aperture by the rapidly-revolving rolls; it will be understood by the transverse

section, fig. 2, that the mandrel is firmly held in its place by the shoulder, *b*, coming in contact with the front bars, *c*, the end of the mandrel extending no farther than the centre of the rolls, and thus preventing the hole in the centre of the barrel from being collapsed by the outward pressure from the rolls. The barrel being now welded, it requires only to be moderately heated and passed through the other grooves, which are so formed as to give its proper size and required form. This operation completes the forging of the barrel, with the exception of a piece of iron suitable to screw the nipple to, which is placed under a forging machine made for this particular purpose, after which it is bored or turned, and placed under other cutting tools to bring it to its proper shape.

The barrels are now ready for *proving*, which consists in firing them in a building in which their explosion can do no harm, with a charge four or five times as great as they will have to bear when in use. A great number of barrels are fired at once, by laying them upon a strong framework of wood, with their touch-holes downwards, and connected with a train of powder which is conducted outside the building, within which is laid a heap of sand to receive the bullets. They are then carefully examined, and such as show any defect are returned to be reformed, after which they must be proved again, while such as have stood the test satisfactorily are stamped with a distinguishing mark.

GUN-CARRIAGE. [ORDNANCE.]

GUN-COTTON. [COTTON, GUN.]

GUN-FACTORIES. [ORDNANCE.]

GUN-SHOT WOUNDS. Under this head writers on military surgery have usually considered not only all the injuries produced by cannon-balls, bullets, &c., striking against the body, but those which arise from the projection of stones, splinters of wood, and other substances broken off and thrown about by heavy balls, or by the explosion of shells, &c. The former are alone properly included in this term.

When a shot strikes the body, it seldom produces much immediate pain; a slight stinging sensation is felt, but the wounded man often becomes aware of the injury only by his inability to move the part, or by feeling a trickling of blood. Whole limbs are known to have been shot off in the heat of action, without the consciousness of the individual. Sometimes, when discovered, the injury produces but little effect on the system: the courage and intellect remain unaffected; the pulse and respiration unaltered. Most frequently, however, if the injury be at all severe, it is followed by intense depression; the man becomes deadly pale, and is covered with profuse sweat; he trembles, and imagines death instantly at hand; he has shivering, nausea, and sickness, and remains unconscious of pain from his wound. These symptoms may soon subside if stimuli be given; but if they continue unabated for some hours they afford strong reason to fear that some important organ has been injured. If the heart or the brain be struck, the man is often seen to leap from the ranks into the air, and fall at once dead.

A part may suffer seriously from a shot without the skin being injured. These cases were long considered by surgeons (as they are still popularly) to be owing to the wind of the ball—that is, to the

impulse of the air, set in motion and compressed by its swift passage. The real cause of this kind of injuries is, that the ball, whose force has, perhaps, been somewhat spent by the obstacles it has previously met with, strikes the part obliquely, and therefore with only a small part of its surface, so that the force applied is not sufficient to break through the skin, which is not only remarkably tough and elastic, but, being placed on soft tissues, which serve it as a cushion, will yield considerably without tearing. The muscles and other tissues beneath the skin, however, being compressed between the ball and the bones, are more or less injured; there may be only a common bruise produced, but frequently the parts are found completely disorganized, broken down into a pulp with the blood effused from the vessels (often of considerable size) that have been ruptured, and sometimes even the adjacent bones are split and broken into fragments. If the ball penetrates the skin, a ragged opening is seen where it entered, with its edges inverted, and appearing somewhat smaller than the ball itself. The part around has a bluish or black colour from the bruise, and the cellular tissue in the track becomes black and dead. If it has struck a part perpendicularly, the ball will most likely enter straight; but if it have struck obliquely, it may be altogether slanted off, or at least its course through the skin will be made more oblique, so that it will fall on the subjacent muscles at a still more acute angle than it did on the surface of the body. Its force too being somewhat expended, it will be the less likely to penetrate the dense fascia of the body; and hence it is often found to have run for a considerable distance beneath the skin, till its force is completely spent, or till, meeting with a greater obstacle to its course onwards than outwards, it passes through the skin again, at a part considerably distant from that at which it entered. This remark, however, is only true of the old round ball. The new conical ball, now almost universally employed in warfare, is not thus deflected, but passes straight through the part, destroying all before it. The peculiar shape and motion, together with the great velocity of the conical ball, impart to its wounds characters of special severity.

When the ball passes quite through the part, the aperture by which it makes its exit has, in general, characters just the reverse of those which we have mentioned as belonging to that by which it entered. Its edges are everted, it looks somewhat larger than the ball, and it is less bruised. In these cases no foreign body may be found in the track of the wound.

Lastly, a part of the surface, or of the whole substance of a limb, or of the trunk, may be completely shot off, either by one large ball, or by a whole charge of small shot. The surface thus left is uneven, ragged, and bruised, the vessels and nerves lie exposed, or hanging out, the bone protrudes, and is often split up, even to the next joint.

Gun-shot wounds partake of the natures at once of penetrating, lacerated, and contused wounds, and they present the characters of all these in an extreme degree of intensity, from the velocity with which the ball, ill fitted by its shape for penetrating, has been propelled. The general rules of treatment are, however, the same as for similar injuries from common

causes, but there are some specialities requiring attention. If, on examination of the wound (which should be made as much as possible with the finger), the ball and the substances it has carried in with it be felt tolerably movable, and in a part where forceps can be easily applied, they should certainly be at once extracted, and sometimes it will be advisable to dilate the wound by incisions along its sides for this purpose.

It has been already said that the ball may pass through a part, and lodge just beneath the skin of the opposite side, or that, after a circuitous course, it may be found under the skin at a distance. In either case, if it can be felt, it should be cut down upon and removed, the usual precautions as to avoiding blood-vessels, &c., being attended to. If the ball or other substances be not extracted at first, and remain fixed after the sloughing and suppuration, no further attempt to remove them should be made till the inflammation that has supervened is fairly subdued: then, if much irritation continues to be excited, if abscesses form about its track, and much constitutional disturbance is produced, it may be necessary to use every effort to find out their seat, and if possible remove them.

Whether the ball be extracted or not, the simplest possible dressings should be at first applied. Lint dipped in cold water covered with oil-skin, is the best and most comfortable application.

The question of amputation, when that operation is applicable, must be decided as in common cases by the character of each; no general rule can be given except that amputation will be advisable in many cases in military practice in which, in civil practice, it would be scarcely justifiable.

Secondary hæmorrhage not unfrequently ensues, when the parts around the track of the wound slough by ulceration of the larger vessels injured by the ball. The bleeding vessel must, if possible, in this case, as well as if it is observed at the first receipt of the injury, be at once cut down upon, and tied both above and below the opening.

GUNNERY, or the science of artillery, is that branch of the art of war which comprehends the theory of military projectiles, and the method of the employment of ordnance in the attack and defence of fortresses and positions. The introduction of heavy guns or cannon into the western part of Europe cannot be traced to an earlier period than the commencement of the fourteenth century, although a species of artillery, similar to our cannon, must have been common in the far East, in India and China, many ages before. When first employed by European nations, cannon received the name of *bombarda*, on account of the noise they made; and are described as mere cylinders like barrels, constructed of long bars of iron soldered together lengthwise, and strengthened by iron hoops. The celebrated Mons Meg, at Edinburgh Castle, is a good extant example of this kind of gun. The upper part of the chambers being made to open for the admission of the can which held the charge. The cannon of this period were fixed on sledges, and made of large calibres, for the purpose of throwing stone balls, some of which were five feet in circumference. Guns of this sort were unwieldy and unmanageable, and of course unfit for quick or expeditious use, and incapable of any precision in firing. Cannon are stated to have been first employed for

naval purposes on the Baltic Sea in 1350, and by the Venetians in 1380.

It appears to have been early noticed that the line of flight taken by projectiles described with tolerable accuracy a definite mathematical curve; and greater accuracy of aim, it was naturally thought, might be attained by giving attention to the mathematical and mechanical conditions of the discharge. The first author professedly treating on the flight of cannon shot was Nicholas Tartaglia, a distinguished Italian mathematician, who in 1537 published his work, '*La Nuova Scientia*.' He showed that no part of the track of a projectile is a straight line; and to him artilleryists owed the invention of the *Gunner's Quadrant*. Later investigations showed that the path of a projectile, supposed to move without resistance, is always a parabola. This interesting proposition was first discovered by Galileo ('*Dialogues on Motion*,' 1638), and it follows very readily from the doctrine of the composition of motion, combined with the laws which that philosopher established concerning the fall of heavy bodies. [PROJECTILES.] Galileo expressly says, however, that this curve would be described by the shot if it were not resisted by the air, and he proposes a method of finding the effects of that resistance. Subsequent writers, with the exception of Newton and Bernoulli, till the time of Robins, 1742, assumed that the atmospheric resistance was but nominal, and consequently asserted that all shot described parabolas in their course. Some practical artilleryists, or officers in charge of the working of guns, in the meantime wrote treatises of some value on gunnery, without adding much to the theory of the art. The real founder of the science of gunnery was Benjamin Robins, whose work, the result of long and elaborate experiment, entitled '*New Principles of Gunnery*,' appeared in 1742. It was soon found in practical cases on a large scale, where the velocity of a projectile is considerable, the resistance of the atmosphere is so great as to render the Galilean proposition of little or no use; and a complete determination of the path, including all the circumstances which may influence it, is attended with difficulties almost insuperable. It appeared from Robins's experiments, that the resistance of the air to an iron ball of $4\frac{1}{2}$ inches in diameter, moving at the rate of 800 feet per second, is equal to four times its weight; and that where the velocity is much greater, the resistance increases much more rapidly, or nearly as the square of the velocity. His experiments appear to have been conducted with defective smooth bores, inasmuch as he found a ball sometimes deviates three or four hundred yards laterally, without any apparent reason. By means of the BALLISTIC PENDULUM, he measured the speed of balls at the very cannon's mouth. Using the work of Robins as a basis, Euler, towards the end of the eighteenth century, extended our knowledge of this subject considerably. The mathematician and physicist, Dr. Hutton, laboured successfully in the same field. From the experiments of the latter it was found that the resistances that a shot meets in passing through the atmosphere, are rather in a higher ratio than the squares of the diameter of the ball. It was found, also, that there is a gradual increase in the exponent of the resistance as the velocity increases.

As the parabolic theory of gunnery, which this speculation on military projectiles is called, continues to have a place in treatises on the subject, it may be proper to indicate the fundamental proposition, and explain a little the principal deductions that are usually made from it.

Let AB represent a horizontal line on the ground,

and ΔG the produced axis of the gun at A ; then, if Δc be taken on ΔG to represent the space which the shot would describe in that direction by the force of the powder in a small portion of time, and Δa , or cb , the space through which the shot would descend by gravity in the same time; by the theory of the composition of motions, the shot would describe the diagonal Δb in the same time, and Δb may be taken to represent the velocity at b in the path. Producing Δb and making $b'c'$ equal to Δb , the line $b'c'$ will represent the space which would be described by the shot in an interval of time equal to the former, if the action of gravity were to cease; then if we make $b'a'$, or $c'b'$ equal to Δa , to represent the deflection caused by gravity in this next interval of time, the shot would evidently describe the line $b'b'$ in the same time; and this would represent the velocity in the path at the end of the second interval. Therefore, producing $b'b'$, making $b''c''$ equal to $b'b'$, and proceeding as before, we should have a series of points, $A, b, b', b'', \&c.$, in the path of the shot; being considered as a curve, the several lines $\Delta c, b'c', b''c'', \&c.$, would become tangents at those points.

On account of the equality of the lines $a\delta$ and $b\epsilon'$, $b\delta'$ and $b'\epsilon$, &c., respectively, it is evident that the parallel vertical lines passing through A , b , b' , b'' , &c., will be equally distant from each other; and as the deflections which are produced by the action of gravity in equal times are equal to each other, we have also $c b$, $c' b'$, $c'' b''$, equal to each other, which is a known property of the parabola. And thus the trajectory of the shot is proved to be that species of curve.

The tangential spaces $A, C, b', b'', \&c.$, being, by hypothesis, described in equal times, they may be taken to represent the velocities of the shot at the points $A, b', b'', \&c.$, in the curve; and these being resolved in directions parallel and perpendicular to $A B$, will give the velocities of the shot in the horizontal and in the vertical directions respectively at the same points. It is evident from the equality of the distances in directions parallel to $A B$, between the vertical lines passing through $A, b, b', b'', \&c.$,

that the horizontal velocities will be the same at every point in the trajectory.

The initial velocity of the shot and the angle BAG , or the elevation of the gun, being given, if the vertical line AI be taken to represent the height due to the initial velocity, and IH be drawn perpendicularly on AG ; on making AG equal to 4AH , and drawing GB perpendicularly on AB , the length of the line AB will express the extent of the range. This will be a maximum, the original velocity being given, when the angle BAG is 45° ; and it is evident that to every other range there will correspond two angles of elevation, of which one will exceed 45° as much as the other falls short of it. The whole time of flight is equal to that in which a body would descend by gravity through a height equal to GB .

The following circumstances relating to the path of the shot is proved by writers on dynamics:—1. With equal initial velocities, the ranges are proportional to $\sin. 2 \text{ B A G}$, or the sine of twice the angle of elevation. 2. In the same case, the greatest height, E D , varies with $\sin. 2 \text{ B A G}$. 3. When the elevations, B A G , are the same, the ranges are proportional to the squares of the initial velocities. 4. The times of flight vary with the sines of the angles of elevation. The theory of the motions of projectiles would therefore be abundantly simple if it were permitted to neglect the effects produced by the resistance of the air during the flight of the shot; but, in fact, when high charges of powder are employed, the trajectory bears no resemblance to any other kind of curve, and can only be expressed by equations of a transcendental nature.

The mathematical theory of gunnery, from the resistance of the air and many other disturbing causes, general and incidental, has been found of little avail in practice. As an essential datum in calculation, it is of great service; but the practical artillerist deduces his rules from experiment, superimposed upon theory, and the following are a few of the maxims thus arrived at:—

For a given charge and weight of projectile, there is a certain length of bore for the gun that gives the greatest velocity, because in this length the full combustion of the powder is realized in impelling the shot before it leaves the muzzle. If the gun is short of the required length, a part of the powder will be expelled undecomposed; and with more than the proper length, the combustion is spent too soon; the ball having to contend with the friction of the gun in making its escape, so much of the impulse given to it is thus lost under the most disadvantageous circumstances. Additional length given to the gun, with a proportionate increase of charge, increases the velocity in the proportion of the cube root of the additional length.

The elasticity of the air affects its resistance, so as to exalt the effect on the shot as it passes through it, by causing the condensation of the air in front, and its rarefaction behind. The displaced air behind does not return freely to fill up the vacuum, until the speed of the ball is reduced to 1400 feet per second. The maximum effective velocity is computed to be 1600 feet, and that, or any higher speed, is reduced to 1400 feet, after a flight of 400 feet.

The resistance to bodies by the air is as their surfaces; in the case of round or cylindrical bodies

as the squares of their diameters; and the power of such bodies themselves to overcome resistance is as their weights, or the cubes of their diameters. Hence the great range of solid as compared with hollow shot. Solid shot, impelled with equal velocities and elevations, range as their weights—the heavier overcoming the atmospheric resistance better than the lighter. Shot of the same weight and diameter will range according to their velocities, but obviously not in direct proportion, for the retarding power of the atmosphere varies as the square of the velocity. Velocities of shot of equal diameters are as the square roots of the charges.

The influence of the atmosphere in retarding shot is well exemplified in the gradual diminution of velocity experienced by a projectile discharged from a 32-pounder, whose initial velocity is taken at 1600 feet per second:—

Velocity, 500 yards from the gun, 1126 feet.

" 1000	"	" 1000
" 1500	"	" 608
" 2000	"	" 465
" 2500	"	" 367

What is called point-blank range, is the distance from a point on the ground, vertically under the chamber of the gun or howitzer, to the point at which the shot strikes the ground after the discharge—the axis of the bore being supposed to be in a horizontal position parallel to the ground if the latter should be inclined to the horizon. It is experimentally demonstrable, that a shot dropped from an equal height with the axis of the gun, and another shot at that moment fired point-blank from the gun, they will both strike the ground at the same instant of time. This same fundamental proposition was in form established by Tartaglia to the effect, that the trajectory or path of a point-blank discharge, is in time equal to that taken by a ball in falling by gravity from the muzzle of the gun. The following table shows the effect of varying the charge and elevation on different sorts of guns:—

Ordnance.	Elevation.	Charge.	Range in Yards.
12-pounder iron gun, ...	Point-blank,	4 lbs.	300
	1 degree,	"	700
	3 degrees,	"	1200
	6 "	"	1800

With a 12-pounder, and 1·75 lbs. of powder, Whitworth has attained a range at 35° of 10,000 yards, or nearly six miles, being about the same distance that an old-fashioned musket-bullet would go, *in vacuo*, at 45° elevation.

The recoil of a gun on its discharge is a consequence of the well-known law in physics, that action and reaction are equal and opposite in direction. This effect is to be overcome as much as possible; and in the case of the mounting of the heavy Armstrong guns on dwarf platforms, the result has been the production of a severe recoil. The weight of the gun itself, and its secure attachment to a ponderous carriage, and by making the beam of the gun carriage, by which it fits into the waggon that goes before, so long that it lies at an acute angle to the ground, are the best counteractives. The existence of an interval between the rear of the shot and cart-ridge, which is apt to occur in breech-loaders, increases the recoil; and rifled guns recoil more than smooth bores. When the shot is too heavy for the gun, a severe recoil is a consequence. The momentum of the free recoil being the product of the weight of the shot into the velocity, its amount is easily calculated. It is held as a general principle among artillerymen, that it is desirable to obtain the lowest possible trajectory, and to do this they should put as much powder into the gun as it can consume. The common charge of a 24-pounder gun being one-third the weight of the shot, or 8 lbs., the momentum of both shot and gun, in the recoil, will be 1600 (the initial velocity) $\times$ 24 = 38,400, which, divided by 5600, or the gun's weight in pounds, gives about seven as the unpurged kick or recoil; if the gun is attached to a carriage, the weight of it must be added to that of the gun for a divisor. The service charges of the Armstrong rifled 100-pounder gun, 7 inch bore and four tons weight, and of the Whitworth 150-pounder same calibre, 7 tons, are severally 14 lbs. and 25 lbs., or about one-sixth of the weight of the shot. The quantity of powder that a gun can consume depends on its calibre.

As regards the penetrating power of guns, this has recently been tried variously, and in innumerable instances, by the 'Committee on Iron,' acting under the orders of the British Admiralty. Mr. Whitworth's success in this, by means of peculiarly formed steel projectiles, has been remarkable, when solid elongated steel shot, and hollow shell of the same form, from a 70-pounder have pierced 4½ in. plates of iron. It was found by experiments against a martello tower at Eastbourne, with a range of 1832 yards, that solid spherical shot from the 40-pounder Armstrong penetrated into good masonry from 47 to 65 inches, and from an 80-pounder Armstrong 51 to 90 inches. For other particulars relative to the art of gunnery, the reader is referred to **LOADING, PROJECTILES, WINDAGE, &c.**

GUNPOWDER, a mixture of nitre, sulphur, and charcoal, possessing great explosive power. The proportions of these ingredients vary according to the uses that are to be made of the powder:—

	Common Gunpowder.	Shooting Powder.	Shooting Powder.	Mining Powder.
Saltpetre, . .	75	78	76	65
Charcoal, . .	15	12	15	15
Sulphur, . .	10	10	9	20

The explosive force of gunpowder depends upon the sudden formation of nitrogen and carbonic acid gases, which, at the high temperature at which they are evolved, may be considered as amounting to about 2000 times the volume of the powder employed. The fetid odour that attends the explosion of gunpowder comes of sulphide of potassium that is formed. The Chinese have long been acquainted with the use of gunpowder, and that as early as the year A.D. 85; and singularly enough, the composition of their powder in the 100 parts was, on analysis, found to be almost exactly that employed by European nations, as the following table will show:—

	Nitre.	Charcoal.	Sulphur.
English, . . .	75·	15·	10·
French, . . .	75·	12·5	12·5
Prussian, . . .	75·	13·5	11·5
Chinese, . . .	75·	14·4	9·9

It was very probably also an invention of the Greeks, and employed by them in the fabrication of fireworks. It has been asserted upon doubtful evidence that the knowledge of this substance was conveyed to Europe from the Arabs by the Crusaders; and it has been further alleged, that the Arabs employed it at the siege of Mecca in 690, and that they obtained a knowledge of it from India. The earliest authentic record that we have of this composition is to be found in a work written by Roger Bacon at Oxford in 1216, and entitled 'The Secrets of Art and Nature,' wherein he states, that 'from saltpetre and other ingredients we are able to make a fire that shall burn at what distance we please, and that sounds and coruscations resembling thunder and lightning might be formed in the air, much more to be dreaded than those that happen naturally, inasmuch as by its power armies and cities might be destroyed.' Roger Bacon has been supposed to allude in an enigmatic way, by a formula of Latin words, to the composition of gunpowder. A knowledge of its destructive power, and the advantages to be derived from it in war, is said to have originated early in the fourteenth century, through an accidental discovery of Bartholdus Schwartz, a German chemist: while operating in a mortar with a pestle on a mixture of charcoal and nitre, an explosion occurred which blew the vessel to a considerable distance. The introduction of cannon into the operations of warfare by sea and land soon followed the discovery of gunpowder; as we find the Moors using artillery against Alonzo, king of Castile, in 1343 and 1346. Edward III. of England used five field-pieces against the French at the battle of Cressy. Cannon, and of course gunpowder, are said to have been first employed for naval purposes on the Baltic Sea in 1350, and by the Venetians in 1380.

In the manufacture of gunpowder, the nitre (nitrate of potash) and sulphur must be pure, the charcoal carefully selected and prepared, and the whole perfectly mixed in fine powder. This mixture is moistened, ground, and pressed into a cake; it is then dried and granulated, and, associated with plumbago in powder, it is afterwards polished by attrition in revolving barrels. The granular form of the powder increases the rapidity of its combustion, by enabling the flame to penetrate it so as to kindle every grain nearly at the same time. For this rea-

son, the powder used for artillery and mining, where it is desirable the combustion should be comparatively slow, is coarse-grained. The corning or graining of the powder is effected in wooden mortars, by wooden pestles actuated by machinery, and a certain number of blows is given to a definite amount of the material. Parchment sieves are in succession employed to separate the grains of a required size from the pulverized mass. The process of glazing the powder by attrition then follows the operation of corning. Another method is that of pressing the composition into a firm cake in the corning house; after which it is broken up into small lumps, and the graining process is conducted in revolving sieves, each containing a flat circular piece of lignum-vitæ. The sieve-holes are sized, to permit the escape through them of the grains as they are formed by the abrading action of the plate of wood. The grains are separated from the dust by proper sieves and reels; they are then hardened, and the rougher edges are taken off by being run a sufficient length of time in a close reel, which has a proper circular motion given to it. A cubic foot of good gunpowder should weigh about fifty-eight pounds; and two ounces of it when exploded in a mortar eight inches in diameter, and placed at an angle of 45°, should throw a sixty-eight pound shot about 270 feet. Gunpowder is sometimes tried by placing two heaps of about sixty grains each upon clean paper, three or four inches asunder, and firing one of them by a red-hot wire. If the flame ascends quickly with a good report, sending up a ring of white smoke, leaving the paper free from specks and not burnt into holes, and if no sparks fly from it so as to set fire to the contiguous heap, the powder is good. The temperature at which gunpowder explodes is about 600° Fahr.

White Gunpowder.—In this composition, the charcoal of the ordinary gunpowder is substituted by the carbon contained in tannic or gallic acid, or the resin of commerce, and a mixture of chlorate and nitrate of potash. This new gunpowder—the discovery of Ehrhardt, a German—is stated to possess three times the explosive force of that now in use, and to be one-half cheaper. It leaves little or no solid residuum when exploded. It can be stored in magazines with safety, by the resin and potash salts being kept separately, and mixed as wanted.

Protected gunpowder—the invention of Mr. Gale—is a method of rendering ordinary gunpowder inexplosive. The means employed for this purpose is simply glass ground down to an exceedingly fine powder, which, on being mixed with the gunpowder, prevents it from exploding, even if touched with a red-hot iron. Three pounds of pounded glass to one of the powder is found to be the safest proportions. With equal parts of each the gunpowder will burn, but not explode. Slow matches may be burned in vessels holding gunpowder mixed with the protective powder, and they only serve to ignite a few grains. A red-hot poker may be stirred through the mixture without ignition. Even a quantity of pure gunpowder may be exploded in the centre of the protected powder, and no other effect will follow but the dispersion of a part of the mixture by the explosion. The mixture can be stored in magazines or on shipboard, or transported by land to any point, without more risk than attaches to commodities in general.

This novelty of protected gunpowder assists, as by experiment, to explain the theory of the ignition of gunpowder under ordinary circumstances. That particle of gunpowder on which a spark falls undergoes combustion, which it transmits to adjoining particles, and these to others with such rapidity, that their united inflammation takes the form of an explosion. The pounded glass mixed with the gunpowder acts in keeping the particles of the latter apart, and so prevents the local transmission of the necessary heat to cause ignition of the mass. Besides, the glass powder melts under the intense heat caused by the ignition of the gunpowder when it may be fired by any heated body, and it surrounds the spot with a glassy flux, which prevents sparks, and intercepts the heat. The chemical changes produced by the explosion of gunpowder are rather complex, and are attended with the production of a variety of new compounds. The most simple representation of the reactions that take place, and of the chief products that are formed, is expressed in the following equation— $\text{KO NO}_3 + \text{S} + \text{C} = 3 \text{CO}_2 + \text{N} + \text{KS}$: or otherwise, from the nitre, sulphur, and carbon of the powder, there result carbonic acid three parts, free nitrogen, and sulphide of potassium. Doubtless carbonic oxide, sulphurous acid, and sulphuretted hydrogen are also at the same instant formed from the same original ingredients.

The exports of gunpowder from the United Kingdom in 1864 amounted to 15,466,844 lbs., of the value of 432,208*l*. The whole of this was British and Irish produce. The countries taking the largest quantities were Western Africa, 3,614,088 lbs.; India and Ceylon, 2,102,305 lbs.; China, 1,755,189 lbs.; Chili, 1,466,737 lbs.; Brazil, 1,432,355 lbs.; Australia, 940,460 lbs.; and British North America, 876,378 lbs.

GUNPOWDER-PLOT. [FAWKES, GUIDO.]

GUNDAMUK, a village of Afghanistan, 28 miles W. from Jellalabad. Here the last surviving portion of the British force (100 soldiers and 300 camp-followers) retreating from Cabool in 1842, was massacred, one man only making his escape.

GUNJAH, the Indian name for the dried hemp plant (*Cannabis sativa*) before the resinous juice has been removed. It is chiefly sold for smoking with tobacco.

GUNSTOCKS are turned by machinery from strong light wood. Walnut-wood is best adapted and principally used for the purpose. In 1863, the quantity of stocks for guns imported into the United Kingdom was 28,882 cwt*s*., value 65,465*l*. Sardinia supplied 22,398 cwt*s*., value 50,769*l*.; Belgium 3482 cwt*s*., value 7891*l*., and other parts 3002 cwt*s*., value 6805*l*. In the same year 160 cwt*s*., value 363*l*. were exported.

GUNST, PIETER VAN, Dutch portrait engraver, was born at Amsterdam about 1667. He engraved a set of ten full-length portraits, after Vandyck, from drawings made in England in 1713 by Arnold Houbraken. He also engraved a set of portraits after Vander Werff, for Larrey's 'History of England,' and he engraved the portrait of Franciscus Junius, after Vander Werff, which is inserted as a frontispiece to the 'Pictura Veterum,' Rotterdam, 1694. His works are extremely neat in execution, especially the heads. Among his historical or figure pieces,

which are inferior to his portraits, are nine Loves of the Gods, after Titian. The date of his death is not known.

GUNTER, EDMUND, was born in the county of Hertford, but of a family originally from Gunter's Town, in Brecknockshire. He was educated on the royal foundation at Westminster School, and elected from thence to Christchurch College, in Oxford, in the year 1599, being then eighteen years of age. He invented the sector, and wrote the description and use of it in Latin. He was appointed professor of astronomy in Gresham College, March 6, 1619. He died on the 10th of December, 1626, about the forty-fifth year of his age.

Gunter's writings (the 'Canon Triangulorum' excepted, which is a table of logarithms) consist almost entirely of a description of graphical methods of constructing problems in trigonometry, navigation, &c. He was the first who laid down a logarithmic scale upon wood, and used it for the purposes of the draughtsman. This scale is still used, and goes by his name. The common chain used by surveyors also goes by his name. The first observation of the variation of the compass is due to Gunter.

Gunter is the first who introduced the words cosine, cotangent, &c., in place of sine of the complement, &c. In the preface of the 'Canon,' he speaks of the 'sine of the complement, which in one word may be called the cosine,' as if he were introducing a new word. There is also the testimony of Briggs ('Arith. Log.,' cap. 13) that Gunter suggested to him the use of the arithmetical complement. Whatever, in short, could be done by a well-informed and ready-witted person to make the new theory of logarithms more immediately available in practice to those who were not skilful mathematicians, was done by Gunter.

GURNARD. [TRIGLA.]

GURWAL. [HINDUSTAN.]

GUSTAVUS ERICKSON, commonly called *Gustavus Vasa*, a descendant of the ancient Swedish kings, was born May 2, 1490, at Ockestadt, near Stockholm. The independence of Sweden, which had been recovered by a successful insurrection, being again lost through the success of the Danes, Christian, the Danish monarch, caused himself to be crowned king of Sweden. Before his coronation he promised to release all prisoners, and to maintain the rights and freedom of the Swedish nation; but within three days after, on November 8, 1520, he violated his promise, by ordering the chiefs of the most respectable Swedish families, and also the members of the senate, to be arrested, and afterwards beheaded in the market-place. Thus perished in one day eighty-four persons, all belonging to the first families, and among them the father of Gustavus Vasa. The Danish troops then rushed upon the unarmed multitude, and massacred all who fell into their hands, without distinction of age or sex. These executions were continued for several days. In the meantime young Erickson had escaped the prison where he had been confined, and fled to the mountains of Dalecarlia, where he could obtain neither food nor shelter from the peasants, who feared the threats of Christian. He wandered about the country half dead with cold and hunger, but succeeded in obtaining employment for

a short time as a labourer. He was soon recognized, and in danger of being betrayed and taken. At length, after a variety of adventures and some narrow escapes, he succeeded in reaching Rattwik in safety.

Here Gustavus began his preparations for his great undertaking. With unwearied zeal he went from house to house, and from hut to hut, and soon found himself surrounded with a number of resolute combatants. With this force he marched towards Stockholm. His forces increased with each step, and in May, 1521, Erickson was at the head of 15,000 men. Victory crowned the arms of the Dalecarlians, to whom the inhabitants of the plains of Sweden quickly united themselves. At length, after various vicissitudes, Stockholm fell into the hands of Gustavus, and Christian was forced to withdraw to Denmark. The nation which he had freed offered Gustavus the crown of Sweden, but he declined to accept sovereignty. Under the title of Stadtholder, however, he conducted the government of Sweden. But the adherents of the Catholic party and the expelled king of Denmark still continued to disturb the country by their intrigues, and the Swedes, in order to obtain peace and security, again solicited Gustavus to ascend the throne; and in June, 1527, he was solemnly crowned king of Sweden, and became the founder of a new dynasty.

Gustavus Vasa reigned in Sweden upwards of thirty-three years. During this long period he displayed such virtues and talents for government, that he acquired fresh and imperishable claims upon the gratitude of his country.

GUSTAVUS ADOLPHUS, King of Sweden, was born on December 9, 1594. He was the sixth monarch of the dynasty of Vasa. His father, Charles, had been declared king of Sweden to the exclusion of Sigismund, the heir of the elder line of the house of Vasa. Charles died October 30, 1611, leaving the Swedish sceptre to his son, then in his seventeenth year. As long as Charles lived, Sigismund never ventured to renew his claims to the crown of Sweden; but upon his death he invaded Sweden, and laid claim to the crown for his son Ladislaus, then a minor; but Gustavus fought successfully against the czar of Russia, the ally of Sigismund, and also against Sigismund himself, until, by the mediation of England and Holland, a peace was concluded in 1629, upon the most advantageous terms for Adolphus. Gustavus next declared war against Austria, his principal motive being to protect the oppressed German Protestants, notwithstanding that the ground of quarrel alleged in his declaration was the enmity shown to Sweden by Austria, and the violation of her territories.

Gustavus landed in Pomerania on the 24th June, 1630, with not more than 8000 men. He made himself master of the islands of Usedom and Wollin, and pressed Bogislav, the duke of Pomerania, so warmly, that he was compelled to agree to a treaty by which the town of Stettin was put in possession of the conqueror, and the whole country placed at his disposal.

The army of Gustavus was reinforced by six Scottish regiments, under the conduct of the duke of Hamilton, and he provided himself with money by raising a contribution of 50,000 rix-dollars in Pomerania. After several other successes, he divided his

force into four parts. One division, under the duke of Lauenburg, was ordered to the relief of Magdeburg; General Bauditz was sent to make an attack upon Kolberg; Horn was left with a garrison in Stettin; and Gustavus himself encamped at Ribbenitz in the duchy of Mecklenburg. While lying there, he received a letter written by the Emperor Ferdinand, containing proposals for peace, in which he made the most advantageous offers to the Swedish king, including the possession of Pomerania. Gustavus rejected these proposals, and continued to make himself master of the towns and fortresses of Pomerania and Mecklenburg. By the end of February, 1631, in the course of only eight months, he had already taken eighty fortified places; but the towns of Rostock and Wismar yet remained in the hands of his enemies. The emperor sent against him Field-marshal Tilly, at the head of the Imperial army. The army of Gustavus pressed forward into the heart of North Germany, gaining continual victories, and on August 1, 1631, encamped near Wittenberg, where Gustavus received Count Arnheim, the ambassador of the elector of Saxony. A treaty was quickly concluded, by which the Saxon dominions were opened to the king of Sweden, and the whole military power of the electorate placed under his command; the elector to provide the army with ammunition and provision, and to conclude no peace with Austria without the consent of the king of Sweden. Gustavus then prepared to encounter Tilly, who had advanced against him to Eilmarschen. On the 7th September, 1631, they met on the plains of Leipzig. The force of the king of Sweden, to which the Saxon troops under Arnheim were joined, amounted to about 40,000 men; Tilly's army was somewhat more numerous. The victory was long doubtful; but at length Tilly's defeat was complete.

All Germany was now open to the Swedes, and Gustavus hastened forwards in an uninterrupted course of conquest. But the progress of the Swedish arms excited the jealousy and apprehension of the whole German population—even among the Protestants. Gustavus was also accused of having designs on the Imperial crown. His allies became lukewarm, and the inhabitants everywhere viewed the Swedes with dislike. Upon the defeat of Tilly at Leipzig, and the Saxon army making itself master of Bohemia almost without opposition, Ferdinand called in Wallenstein, who drove the Saxons out of Bohemia, and threatened Gustavus, who in the meantime had gained a second victory over Tilly, in which that general lost his life. Wallenstein took up a strong position in the neighbourhood of Nürnberg. In fruitless attacks upon the camp, and through hunger and disease, in the course of seventy-two days, Gustavus lost 30,000 men. At length Wallenstein moved towards Saxony, and on November 1, 1632, he offered battle to his opponent at Lützen.

Gustavus opened the battle to the sound of music, with Luther's hymn, 'Eine feste Burg ist unser Gott.' He led the attack in person, descended at the critical moment from his horse, and killed the foremost of the enemy with a lance. While heading a second attack on horseback against the enemy's cavalry, a ball struck him from behind, and he fell. Duke Bernhard of Weimar, crying out to the Swedes that the king was made a prisoner, inflamed them to such

a degree that nothing could resist their impetuosity, and after a frightful carnage the enemy was forced to retreat. The Swedes gained a victory, but with the loss of their king. A strong suspicion of the crime of assassination rests upon his cousin, the duke of Saxe-Lauenburg.

Gustavus Adolphus married, in 1621, Maria Eleonora, the sister of the duke of Mecklenburg, by whom he had one daughter, Christina, who was his successor.

GUSTAVUS III., King of Sweden, born in 1746, was the eldest son of Adolphus Frederic, duke of Holstein, who had been called to the Swedish throne in 1743. On the 12th of February, 1771, Gustavus III. succeeded to the crown on the death of his father. The country was at this time divided by two factions, the Hats and Caps, as the aristocratic adherents to the Russian or French policy respectively called themselves. Gustavus took the bold resolution of subverting both these parties with the assistance of the people. The execution of the king's plans was commenced by the insurrection of the commandant of Christiansstadt, who issued a violent proclamation against the States-General. Gustavus sent Prince Charles with a powerful force ostensibly to subdue the rebel, but in reality to unite with him. On the 19th of August, 1772, the king began to follow out his plans in person. He arrested the heads of the parties and the most powerful members of the States, and publicly announced his plans for the establishment of a new constitution. The next day the magistracy of the capital took the oaths of fidelity, and the States-General were invited to assemble. Gustavus entered the assemblage in order to submit to them the proposed new constitution. His armed force was apparently sufficient to subdue every scruple of the assembly; but as the constitution only restricted and circumscribed the privileges of the nobility, and did not infringe the liberties of the citizens, it was received by the majority with real satisfaction, and confirmed by oaths and signatures. Those who had been arrested were immediately afterwards released, and the revolution was completed.

The nobility were silenced, but they nourished a secret hatred, which at length broke out in the year 1788, when they prevailed on the States to refuse the supplies while the king was engaged in a war with Russia and Denmark. In order to free himself from the ever-active intrigues of the nobles, the king, on April 3rd, 1789, caused the leaders of the opposition in the Diet to be arrested, and a law to be passed, by which the royal prerogatives were very considerably increased. After varying fortunes in the war, Gustavus concluded a peace on the 14th August, 1790, with his foreign enemies; but the nobility, who apprehended the loss of all their privileges, resolved upon his death. Accordingly they formed a conspiracy under the direction of Counts Horn and Ribbing, and Colonel Lilienhorn; and a nobleman, named Ankerstroem, undertook to murder him. Ankerstroem chose a masked ball, given on the 16th of March, 1792, at Stockholm, as affording the fittest opportunity. The king was warned by some anonymous friend; but he went to the ball, and the assassin shot him through the body. The king suffered with much firmness, and died on the 29th of March. His murderer was discovered and executed, and

many of the conspirators were banished from the country.

GUSTAVUS IV., King of Sweden, son of the preceding monarch, was born November 1st, 1778, and ascended the throne on the 29th of March, 1792. This king displayed, while a prince, a capricious humour and an obstinacy that bordered upon madness. He entered into a negotiation for a marriage with the granddaughter of the Empress Catherine of Russia, and the whole court was assembled in order to be present at the ratification of the marriage-treaty, when he departed secretly, and married a German princess of the house of Baden. Of all the European monarchs he was the most zealous partisan of legitimacy, and he proposed, as the great object of his life, the restoration of the dethroned family of the Bourbons to the crown of France. He involved his country in indescribable difficulties, irritated all his neighbours, and even offended England, his only ally, whom he certainly could not reproach with any friendly feelings towards Napoleon. Gustavus appears to have discovered that a storm was gathering about him, and in order to avert it he endeavoured to possess himself of the funds deposited in the bank of Sweden. At first he made an attempt to get the money by a loan of eighty-two millions of Swedish rix-dollars (about twelve millions sterling); but as the bank commissioners refused to comply with this demand, he resolved to carry his plan into effect by force.

On March 29, 1809, he repaired to the bank, accompanied by a detachment of military, with the intention of taking possession of the money deposited there. By order of the Diet, a resistance was made, and the king arrested, and confined in an apartment, where he raged like a madman. On March 29 there appeared the decision of the Diet, by which Gustavus IV. and all his direct descendants were declared to have forfeited their right to the Swedish crown; and the duke of Sudermania ascended the throne under the name of Charles XIII.

Gustavus left the Swedish territories. During his exile he assumed the name of Colonel Gustavson, and renounced all external observances that might remind him of his former rank. He refused the appanage which Sweden offered him, declined having any communication with his family, and obstinately rejected all assistance from them. He subsisted on the produce of his labours as an author, together with a little pension which he drew as a colonel.

He died at St. Gall, towards the end of the year 1837.

GUSTROW. [MECKLENBURG.]

GUSTO, or GUSTO'SO (Ital. *taste*), in Music, a word (generally written *con gusto*) prefixed to such movements as are to be performed in an elegant and spirited style.

GUTENBERG, believed to be the first inventor of the art of printing with movable types, whose real name was Johannes Gensfleisch, was born in 1397 at Sulgelo, a village near Mainz. During his residence there he became implicated in an insurrection against the nobility, and was compelled to fly to Strasburg, where necessity compelled him to employ himself in mechanical occupations, and by accident he made the discovery so pregnant with future consequences. On returning to Mainz, Guten-

berg experienced the hard fate that most great inventors have to endure from the misconceptions and ingratitude of mankind. The members of the Guild of Writers, together with the priests, persecuted him; his partners Fust and Schoeffer joined with his enemies against him; through litigation he was deprived of all his property; and once more he was forced to turn his back upon the ungrateful town. In the meantime Fust and Schoeffer pursued their business as printers, and thus reaped all the profit, while the inventor was wandering in exile. After many years Gutenberg returned to Mainz, where he died, February 24, 1468. His statue in bronze was set up at Mainz some years ago.

The 'Statuta Provincialia antiqua et nova Moguntina,' quarto, are thought to have been printed by Gutenberg, as well as two or three editions of Donatus, of which fragments only remain. Some have thought the Mazarine Bible to have been a production of his press.

GUTHRIE, GEORGE JAMES, F.R.S., President of the Royal College of Surgeons, &c., was born in 1785, and placed at an early age under the celebrated Dr. Hooper. For many years he practised as a regimental surgeon in North America and the Peninsula. After the Peninsular campaigns he returned to London, and commenced lecturing on surgery, which practice he continued for nearly thirty years. In 1827 he was appointed surgeon to the Westminster Hospital, and in 1833 was elected president of the Royal College of Surgeons. He also held the office of professor of anatomy and surgery; and such was the high opinion the members of the college entertained of his abilities and surgical skill, that in 1842 and 1855 the same honours were again conferred upon him, this being the only instance on record of the same person being three times honoured with this distinguished position. Mr. Guthrie was the author of several works which rank high in the profession; among others, his 'Treatise on Gun-shot Wounds of the Extremities,' 'Clinical Lectures on Compound Fractures,' 'On Injuries of the Hand, Chest, and Abdomen,' 'Diseases and Injuries of the Arteries,' 'On the Anatomy and Diseases of the Bladder and Urethra,' 'Extraction of Cataract,' &c. He died on the 1st of May, 1856.

GUTHRIE, WILLIAM, was born at Brechin in the county of Angus, Scotland, in 1708. He was educated at the University of Aberdeen. He came to London, and became one of the most popular compilers of his day, and must have been one of the most industrious writers ever known, if he was the author of all the voluminous works to which his name is prefixed. Among them are a 'History of England,' 3 vols. folio; a 'History of Scotland,' 10 vols. 8vo; and a 'General History of the World,' 13 vols. But in the preparation of most of these works he is believed to have had little share beyond lending them his name. The 'Geographical Grammar' which bears his name is believed to have been compiled by a bookseller in the Strand, of the name of Knox. Soon after his arrival in London, Cave published the first number of the *Gentleman's Magazine*, and Guthrie, by way of reporting the speeches in Parliament, concocted from such hints as he could gather the debates in the 'Senate of Lilliput,' which

were published in that periodical. In the performance of this duty he was subsequently superseded by Johnson. To what he gained by his pen was, in course of time, added a pension from government. He died in March, 1770, and was buried in Marylebone Churchyard.

GUTHRY, HENRY, a Scottish ecclesiastic, was the son of John Guthry, clergyman of Cupar-Angus in Forfarshire, where he was born soon after the commencement of the seventeenth century. He studied at St. Andrews, and was presented to the church of Stirling. In 1638 he subscribed the Covenant, but he is said never to have had much sympathy with its promoters. In 1647 he was one of those who joined the 'Engagement' for the support of Charles I. against the Parliament, which occasioned his deposition from the ministry. He was succeeded by a celebrated namesake, apparently a member of the same family, James Guthry, who, having shown a resolute hostility to Charles II., his followers, and his ecclesiastical polity, was beheaded for high treason in 1661. The more moderate or cautious Henry was then restored to the benefice. He conformed to the re-establishment of Episcopacy, and was appointed bishop of Dunkeld in 1665. He died in 1676, leaving behind him a MS. 'History of his Own Time,' which was published in 1748.

GUTTA PERCHA. This valuable substance, the name of which is the same in all languages, and which was unknown in Europe previously to the year 1843, is the inspissated juice of a tree which grows in the Malayan forests and the islands of the Eastern Archipelago. In its origin, character, and composition, it is analogous to caoutchouc, but wants the peculiar elasticity of that substance; on the other hand it possesses special and distinct properties, which render it applicable to an extraordinary variety of important uses, and which, within the short time that has elapsed since its introduction into Europe, have given a remarkable development to its manufacture.

The word 'gutta,' in the Malay language, means a gum which exudes from a tree; and 'percha' is derived from 'pertscha,' the particular tree from which the gum is produced.

The merit of first appreciating its value and making it known in Europe, is claimed by two individuals who seem to have endeavoured about the same time, and quite independently of each other, to bring it into public notice, namely, Dr. William Montgomerie, who was for some years surgeon to the residency at Singapore, and Sir Jose d'Almeida, who had been for many years resident in the same settlement. The valuable qualities of the substance were no sooner publicly announced, than it came into general demand. The immediate effect of its discovery may be compared to that of the gold fields in California and Australia; and perhaps no commodity, except the precious metals, has been more eagerly sought after or more highly appreciated.

A knowledge of the article gradually spread from Singapore northward as far as Penang; southward along the east coast of Sumatra to Java; eastward to Borneo, where it was found not only at Sarawak, but also at Brunè and Pontianak on the west coast, and at Reti and Passir on the east.

This eager demand for the precious gum was pro-

ductive of a reckless destruction of the valuable trees that produced it. Instead of simply tapping the trees, as is practised in the case of caoutchouc, the monarchs of the forest were felled; a magnificent product of fifty or a hundred years' growth was cut down, the bark stripped, and the milky juice collected, and poured into a trough formed by the hollow stem of the plantain leaf; and some idea may be formed of the havoc thus made to procure the large supplies which were imported into Singapore, when it is stated that on an average not more than twenty or thirty pounds were procured from one tree. The result was that in the course of four years 270,000 trees were felled. It was therefore apprehended that the tree, although at first sufficiently plentiful, would soon become difficult to be

Gutta Percha Tree.

procured; and this would undoubtedly have been the case, had not the Gutta Percha Company, subsequently formed in England, acted with a wise precaution, and embarked a considerable capital in seeking to promote the tapping instead of the felling of the trees.

For some time after its introduction, the character of the tree remained a mystery. At length, from specimens sent home by Dr. Oxley in 1847, Sir W. J. Hooker was enabled to refer the plant to Dr. Wright's new genus *Sapotaceae*, called by him *Isonandra*; accordingly, he proposed to designate the gutta percha plant *Isonandra gutta*—the name by which it is now known. The tree is from forty to seventy feet high, and from two to six feet in diameter. The wood is peculiarly soft, fibrous, and spongy, pale-coloured, and traversed by longitudinal receptacles of reservoirs filled with the gum, forming ebony-black lines.

The sap coagulates in a few minutes after it is collected; but before the crude gum becomes quite hard, it is kneaded by hand into compact oblong masses. When quite pure, gutta percha is of a greyish-white, but as brought to market it is generally found of a reddish-brown hue, arising from chips of bark that fall into the sap in the act of making the incisions, and which cause the tinge.

The articles now made of gutta percha are numerous and varied. The toughness of the material and the facility with which it may be softened by heat, render it peculiarly apt to receive and to maintain permanently, any form that may be imparted to it. Pressure in moulds, while the gutta percha is in a warm and plastic state, is one of the most convenient modes of giving it a determinate form. Whether wet or dry, its uses are confined to cold purposes, as it is very readily affected and thrown out of shape by heat. For many purposes, naphtha and other inflammable liquids act as cements and even solvents for the gutta percha. It resembles very tough leather, and emits a peculiar odour; its surface is, however, capable of being prepared so as to receive paint, gilding, japaning, bronzing, and other ornamental modifications. The crude substance, as brought to England, is reduced to a pulp by macerating machines, purified by water, combined with many different substances according to the purpose to which it is to be applied, and pressed into sheets or other forms by rollers; and familiar mechanical processes are then sufficient to work up this prepared material to the required forms.

Gutta percha is used for making a vast variety of ornamental articles, too numerous to detail, but which might, if necessary, be grouped into such headings as domestic, artistic, surgical, chemical, manufacturing, agricultural, electrical, maritime, engineering, and ornamental. Perhaps its most important application has been the coating of underground and submarine electric telegraph wires. But apart from these uses, it is more especially to the manufacture of tubes and chemical utensils for the conveyance and conservation of acids, *et cetera*, that the article seems calculated to render the greatest services.

The imports of the raw material amounted, in 1863, to 21,655 cwts., value 224,961*l.*, or an average value of 10*l.* 10*s.* per cwt. India, Singapore, and Ceylon, sent 18,597 cwts.; Borneo, 1854 cwts., and Holland, 875 cwts. The exports were 786 cwts.; value 8165*l.* In the same year 190 cwts. of gutta percha manufactures, value 2493*l.* were imported; and 1418 cwts. of British, value 18,351*l.*; and 106 cwts., value 1274*l.*, of foreign make, were exported. In 1864 the imports had increased to 35,636 cwts.

In Dr. Muspratt's 'Dictionary of Chemistry' is given an invaluable treatise on the properties, composition, and manufacturing processes of this singularly useful article of commerce.

GUTTA SERENA is that kind of blindness which arises from derangement or disease of the nerves of the eye, whether before or after their separation from the brain. The name originated in a notion, long prevalent in the schools, that all diseases are attributable to some deleterious fluid or humour circulating in the blood, or diffused in the substance of the part affected. The epithet *serene*

was intended to intimate the comparative freedom from pain, and the absence of any unpleasant change in the appearance of the eye, which distinguish this class of ophthalmic complaints from others equally destructive of sight. Hence Milton, whose blindness was of this kind, thus addresses Light ('Paradise Lost,' iii. 22)—

'But thou
Revisit'st not these eyes, that roll in vain
To find thy piercing ray, and find no dawn;
So thick a drop serene hath quenched their orbs,
Or dim suffusion veiled.'

and, in the lines to Cyriack Skinner, he notices both the external peculiarity and the cause (by far the most frequent one) of his blindness, as well as the occasional suddenness of its attack:—

'Cyriack, *this three years day* these eyes, *though clear*
To outward view of blemish or of spot,
Bereft of light, their seeing have forgot.'

But the rejection of the humoral pathology has been extended to the nomenclature derived from it; and this fanciful though still popular term, which seems to have been devised expressly for the poets, has given place in modern systems of nosology to that of *amaurosis* (ἄμαυρος, 'blind').

The most frequent seat of the complaint is the retina; the next is probably the brain itself, or that part of the optic nerve which, lying near the cranium, is in contact or communication with the brain, and partakes of its diseases. It may likewise be symptomatic of irritation in some distant organ. The temporary failure of sight during a bilious attack is of this nature. It is sometimes merely hysterical, in which case, though the blindness may be total, it is rarely permanent; and the same remark may be made of a kind of amaurosis which occasionally results from the irritation of worms in the intestinal canal.

Confirmed amaurosis is seldom cured, but in its early stages much may be effected by careful and skilful treatment; and the means may generally be adapted with great precision to the nature of the case, by attentive consideration of its symptoms and history.

Depletion, aperient medicines, abstinence, and a darkened chamber, with mercury, must of course form a part of the treatment when the case is inflammatory; but, when the symptoms arise from exhaustion, an opposite plan of treatment is obviously proper.

GUTTIFERÆ, or CLUSIA/CEÆ, form a small natural order of exogenous plants, inhabiting the hotter parts of tropical countries in both the Old and New World. Their fruit is succulent, juicy, and in many cases resembling a large apple or orange. The Mangosteen (*Garcinia mangostana*) is probably the most delicious of any known; but it has never been seen in a fresh state in Europe, for the tree will hardly exist out of its native, humid, heated atmosphere in the Indian Archipelago. In general the fruit of these plants is acrid and astringent, and quite unfit for food. The most remarkable product of the order is Gamboge, which is secreted by the branches of *Hebradendron cambogioides*, and perhaps some other species. Others yield an astringent gum-resin, called Tacamahaca.

GUTTURAL (Lat. *guttur*, 'the throat'), in Elo-

cution and orthoëpy, a term applied to sounds, letters, or syllables, pronounced or formed in the throat. In music, it is an epithet applied to that style of intonation which the Italians call 'singing in the throat.'

GUTZLAFF, REV. DR. CHARLES, a distinguished Chinese scholar, and secretary to the Hong Kong government, was born in Pomerania in 1803. He was first sent to the East by the Netherlands Missionary Society in 1827; and after spending four years in Batavia, Singapore, and Siam, he went to China, where his critical knowledge of the language and manners of the inhabitants enabled him to enter the country on a familiar footing, and thus obtain a more intimate acquaintance with China and its inhabitants than any other European. He subsequently published his journals, which are of a most interesting character. On the death of Dr. Morrison in 1834, Mr. Gutzlaff was engaged as interpreter to the British Superintendency, which position he held during the war with the Chinese Empire in 1841-42. He afterwards received the appointment of Chinese secretary to the British plenipotentiary and superintendent of trade. This position he held to the time of his death, which took place in 1851.

Mr. Gutzlaff's researches in China have been published in various forms. In addition to his journals of different voyages along the coast of China, he published 'A Sketch of Chinese History, ancient and modern;' 'China Opened, or a Display of the Topography, History, &c., of the Chinese Empire;' 'Memoirs of the late Emperor of China, and the Court of Peking,' &c.

GUYANA, GUAYANA, or GUIANA, is the north-eastern portion of South America, extending from the banks of the river Orinoco southward to those of the river Amazon. It is bounded on the west by the Guainia or Rio Negro, the natural canal of Cassiquiare, and the middle course of the Orinoco. Its surface covers an area of more than 650,000 square miles, but more than five-sixths of it are included within the boundaries of the empire of Brazil and the republic of Venezuela, under which articles these portions are noticed. We limit the present description to those parts which comprehend the English, Dutch, and French settlements, and which cover a surface of about 130,000 square miles. The boundaries between these settlements and the other two portions are only vaguely determined; but for the most part the districts drained by the rivers which fall immediately into the Atlantic Ocean belong to the European nations, while those which are drained by the streams which fall into the Amazon and Orinoco are appurtenances of Brazil and Venezuela respectively.

Surface, Rivers, &c.—The shores of this country are skirted by a mud bank, extending about seven or eight miles out to sea, rendering the approach from the sea exceedingly monotonous and difficult. Low land extends from the coast forty to seventy miles inland, and is mostly on a level with the sea at high water. This land can with difficulty be protected from the sea, but when drained and cultivated, it yields rich crops. In fact, such is the depth and fertility of the soil, that the same land has been productive annually through more than half a cen-

tury, without manure, without rotation of crop, and without a pause.

The high land does not rise immediately from the plain to a great elevation, the hills on its southern edge attaining only a height of from 50 to 200 feet above the plain. Behind these hills the high land stretches out in level or undulating plains, rising here and there into eminences; but farther south ranges of hills appear running north-west and south-east parallel to the coast; or rather to the northern edge of the upper region; and south of them the surface is again depressed and extends in plains. A considerable portion of this inland country consists of extensive savannahs covered with grasses and plants.

The largest river is the Essequibo, which traverses nearly the middle of British Guyana. At a point 230 miles from its mouth, the river is still some hundred yards wide, and forms a great cataract, called King William's Cataract. It is, however, only navigable for large vessels up to its first falls—a distance of 60 miles from the sea. In the wide estuary of the Essequibo there are numerous islands, some of which are extensive. Among them are Hog Island, Wakenaam, Leguan, and Tiger Island.

East of the Essequibo and parallel to it, runs the Demerara, whose sources lie a little south of 5° N. lat. At 5° 25' N. lat. it forms a great cataract, and below it becomes navigable for small craft. This river runs more than 200 miles; and, as it affords an easy means of transport for goods, there are many settlements on its banks.

Farther east runs the Berbice, whose source is situated about 3° 40' N. lat. It has many rapids and cataracts, but is navigable for 165 miles.

The Courantin River forms the boundary between the Dutch and British possessions. At 200 miles from its mouth it is still 900 yards wide. Like most of the other rivers of Guyana, it has many rapids and cataracts, and its course is very tortuous. Near its mouth is an island, Parrot Island, seven miles long. Seventy miles from the sea the tide rises thirty inches.

The river Surinam, which traverses the middle of the Dutch territories, rises somewhere about 4° N. lat. It enters the low plain at about 4° 40' N. lat., and so far it is navigable for river barges. Towards its mouth it increases to a mile in width, and north of Paramaribo it is still wider. Vessels of considerable size can enter it and sail up to that town.

The Marony, which divides the Dutch and French Colonies, has many rapids and cataracts south of Arminia, in 4° 45' N. lat. From this place, to which the tide ascends, as far as its mouth, it is not less than a mile and a half wide, but full of islands. Large river vessels can ascend to Arminia.

The smaller streams are the Pomeroon, the Moruca, the Wai-ini, between the Orinoco and the Essequibo; the Mahaica, the Mahaicony, and the Albany, between the Demerara and the Berbice; and the Canje, which joins the latter immediately before it falls into the sea. All these streams are continually bringing down quantities of detritus, and the coast-line is consequently undergoing considerable changes. In one place the drainage of the estates is blocked up by drift-mud, and in another, incessant exertion is required to repel the encroachments of the sea.

Climate and Productions.—Guyana has two rainy

and two dry seasons. The long rainy season sets in about the middle of April, and lasts till August. The long dry season continues from August to November. February and March constitute the short dry season, but they are not quite so free from showers as the long dry season. The heat is not so great as might be supposed, considering the position of the country near the equator and the lowness of the coast: the trade-winds and the land and sea breezes tend to cool the air. The thermometer, even in summer, seldom rises above 90°, and it does not often descend below 75°. Though Europeans are subject to some diseases on their arrival, it is now well known that the climate of Guyana is more healthy than that of most places in the West Indies. Thunder-storms, hurricanes, and earthquakes are rare.

Few countries on the surface of the globe can be compared with Guyana for luxuriance of vegetation, which shows itself especially in the great number of indigenous plants and the large forest-trees which cover perhaps not less than one-half of its surface. Timber, furniture-wood, and dye-wood are afforded in abundance. Indian corn, rice, wheat, cacao, vanilla, tobacco, cinnamon, mandioc, yams, sweet potatoes, arrow-root, bananas, pine-apples, coconuts, sugar, coffee, ginger, pepper, cloves, nutmegs, and cotton—all are grown in Guyana. The principal attention of the landed proprietors is now concentrated in the growth of sugar and the manufacture of rum; but the timber trade has of late years assumed a very great degree of importance, owing principally to the interest excited in the natural resources of the colony by the Great Exhibitions of London in 1851 and 1862, and of Paris in 1855.

The domestic animals are the same as in England. Black cattle grow to a greater size than in Europe, but their flesh is not so tender nor of so fine a flavour. The wool of the sheep is converted into hair. Among the ferocious animals are the jaguar and cougar. Other animals are the armadillo, agouti, ant-bear, sloth, monkeys, lizards, iguana, alligators, bats, and snakes. The birds and insects are very numerous.

Inhabitants.—Guyana is inhabited by Europeans, Africans, and native Americans. The Europeans are mostly descendants of Dutch settlers, but some are descendants of Englishmen and Frenchmen. The Africans were brought over to cultivate the country as slaves, and are much more numerous than the whites. In British Guyana there are six tribes of natives, who are much more civilized than the aboriginal tribes who inhabit the adjacent countries. Some of them work for the English settlers.

Guyana is, as we observed, divided among Great Britain, Holland, and France.

I. BRITISH GUYANA comprehends the countries extending from the Courantin River westward to the Orinoco, and from the sea-coast to the sources of the rivers Essequibo and Courantin. Its area has been estimated at 76,000 square miles, which considerably exceeds that of the two other territories taken together; but the possession of much of this has been disputed by Brazil and Venezuela. The population in 1861 was 148,026, including about 30,000 Indians. The total number of immigrants of all races introduced from 1835 to 1860 was 90,000, and there are now about 27,000 under indenture on the several estates.

Previous to 1831 the country was divided into three colonies, Essequibo, Demerara, and Berbice, but in that year they were united under one government, called British Guyana. The residence of the governor is in *Georgetown*, formerly called Stabrock, on the Demerara river, a short distance from its mouth. Its wide streets are traversed by canals. The houses are of wood, and seldom above two stories high. Before them are porticoes and balconies, shaded by a projecting roof, which is made of red wood, resembling mahogany. The population is 25,000—the great majority being negroes, or persons of colour. There is an episcopal cathedral and a Smith chapel—the latter erected to commemorate the memory of a missionary who suffered in the cause of the negroes during the struggle for emancipation. There is also a very elegant town-hall, with marble-paved galleries resting on cast-iron columns; a mariners' hospital, numerous churches and schools, astronomical and botanical societies, barracks, theatres, and a market-place surrounded by elegant and well-stocked shops. Owing to the low and swampy nature of the district, the town is unhealthy, and yellow and intermittent fever, diarrhoea, dysentery, and dropsy, are local diseases.

Berbice was first settled by the Dutch in 1626, and remained mostly in the hands of Dutch companies or traders till 1803, when it was finally ceded to Great Britain. The former capital of this province was Old Amsterdam, which was replaced by New Amsterdam, higher up the river Berbice, in 1796. It extends about a mile and a half along the river shore, and each house has an allotment of garden ground around it.

Public affairs in British Guyana are administered by a governor invested with large powers, responsible to the queen in council, and aided by a peculiarly-constituted colonial assembly, based to a great extent on the system under which affairs were formerly administered by the Dutch. The three counties of Berbice, Demerara, and Essequibo, form a diocese of the Anglican church. The colony is altogether divided into seventeen parishes, of which seven belong exclusively to the Church of Scotland, and eight to that of England; while the two in which the towns are situated, have a minister of each church appointed to them. The ministers of both churches, as well as those of the Roman Catholic and Wesleyan, are supported by the state, but independent missionaries throughout the colonies are maintained by their congregations.

The revenue of the colony in 1863 was 266,000*l.*, and the expenditure 267,000*l.*—both sums being rather under those for 1862. The public debt amounts to 600,000*l.*—a great portion of which has been incurred in bringing immigrants to the colony.

The value of the imports in 1863 was 1,121,979*l.*, against 1,107,181*l.* in 1862. The value of the exports was 1,679,885*l.*, against 1,365,295*l.* in 1862. This increase is to be attributed partly to the advance in price of the staple product of the colony, but also to a considerable increase in the quantity exported.

The important colony of British Guyana has made very rapid progress during the last fifteen years, but like other sugar-producing countries, it has had to contend with great difficulties, owing to the com-

paratively low price of the product, and in this colony also with the want of drainage. To meet the necessary low rate of wages, Chinese and Coolies have been imported in large numbers to supply the labour-market. The Chinamen are liked by the planters, who have an agent regularly stationed at Canton to procure recruits. In his last published report (1865) the governor of the colony says:—'There is great room for improvement in the condition of the masses of the people. It is satisfactory, however, to be able to report that, with regard to the immigrant class, which is chiefly located on the estates, a marked improvement has of late years taken place in their dwellings, as well as in the estates hospitals. The Creole population, which is chiefly located in villages, must always be a source of the deepest anxiety. There is so much to be done, so many difficulties to be encountered, and so much obloquy to be endured, that the task of ameliorating the condition of the villagers is anything but an encouraging one. Their stubborn resistance to taxation is the main obstacle to any measure of improvement. I have no doubt that this obstacle will ultimately be overcome, and that means will be obtained to place the villages of British Guyana in a satisfactory condition. It would not be proper for me to omit to notice the fact that in all the villages, so far as my knowledge extends, there are intelligent negroes fully alive to the value of those measures of improvement which the Government is anxious to carry out. There are also some villages in which the well-disposed are much better supported than in others.'

An active commerce is carried on with Guyana by Great Britain—the exports from British Guyana alone amounting to one million and a half annually. In 1863 the sum was 1,510,500*l.*, consisting of unrefined sugar valued at 1,138,792*l.*; rum, 257,507*l.*; wood for shipbuilding, 69,808*l.*; cotton, 27,054*l.*; cocoa-nuts, 4118*l.*, and a few other articles. In the same year the imports from the United Kingdom were valued at 578,006*l.*; of which amount 512,391*l.* was for British produce and manufactures. The principal articles were cotton manufactures, 85,361*l.*; apparel and haberdashery, 50,845*l.*; casks, staves, and hoops of wood, 41,949*l.*; machinery, iron manufactures, ale and beer, coal, drugs, linen and woollen manufactures.

II. DUTCH GUYANA, or SURINAM, extends along the coast from the Courantijn River to the Marony, and between them inland to their sources. The area is 45,000 square miles, and the population in 1861 was 53,700, of whom nearly three-fourths are negroes. Slavery has recently been abolished by the Dutch government, but in lieu of compensation it was agreed that the negroes should labour for a considerable time for their former masters without wages.

The physical character, climate, and productions of the country, are very similar to those of British Guyana, but the natural advantages of the country are not so fully developed, and in some parts the land is totally uncultivated. The principal river is the Surinam, which has a course of 300 miles, but is not navigable for large ships for more than about thirty miles. Dutch laws are in force, and the country is ruled by a governor-general, appointed by the king, and a general council of native freeholders. All religions are tolerated, and the Jews—who are

very numerous in the colony—have establishments and synagogues in many places.

The principal exports are sugar, rum, cocoa, and cotton; but besides these articles, the colony also produces fine woods, cassava, gums, and drugs. The imports consist principally of machinery, cotton goods, iron, &c., and are chiefly supplied from the mother country and the United States; but the exports to Great Britain in 1863 were valued at 109,220*l.*; and the imports thence to 89,077*l.* The total value of the exports is about 500,000*l.* per annum, and the imports half that amount.

Paramaribo, the capital, is about ten miles from the sea, on the western bank of the river Surinam, and contains about 16,000 inhabitants. The streets are unpaved, but wide, and traversed by canals, and lined with orange, lemon, and tamarind trees. The houses are generally two stories high, and built of wood. The town is provided with Lutheran, Calvinistic, Roman Catholic, and English churches, and Portuguese and German Jewish synagogues, and is the centre of the trade of the colony. In an hospital for lepers, 450 patients are maintained at the expense of the colony. Near to it is the fortress of Zelandia, in which the governor resides.

III. FRENCH GUYANA, or CAYENNE, extends along the coast from the river Marony, which separates it from Dutch Guyana, to the Oyapock, which divides it from Brazil. The area is not well-defined, but, according to good authorities, is supposed to be about 18,000 square miles. The population is 23,107. Nearly the whole tract is still covered with large forest trees; and the settlements are neither so large nor so numerous as in British and Dutch Guyana, but the physical aspects, soil, climate, &c., are generally the same. The principal rivers are the Marony and the Oyapock. The colony is divided into two cantons, and its government is similar to that of other French possessions. The Roman Catholic is the dominant religion, although other forms of faith are tolerated. The trade with French Guyana is unimportant, and its chief importance to the mother-country consists in its being the principal seat of her penal settlements, which are maintained at Cayenne at the national charge; all persons sentenced to eight years' hard labour are condemned, on the expiration of their sentence, to reside for the remainder of their lives in the colony, unless specially pardoned by the emperor. The discipline amongst the prisoners is very severe, the labour heavy and continuous, and, as a natural consequence, the death-rate is very high. The number of prisoners at present in the colony is about 6500.

Cayenne is the only town of any importance, and even that is small and mean-looking, although some improvements have recently been effected in the part designated 'the New Town.' The population is about 8000. The name originates in a spice, Cayenne pepper, made of the dried seeds of a native plant, a species of capsicum.

History.—Guyana was discovered, before the end of the fifteenth century, by Vincent Pinzon. The Dutch formed the first settlement about 1590 on the Demerara River, and afterwards at other places. The English settled in 1634 in the neighbourhood of the Berbice and Surinam; but in 1667 the English settlements were given up to the Dutch. The

French occupied Cayenne in 1633. During the last war with France the English occupied the Dutch settlements; and by the treaty of Paris, 1814, they restored only those between the Courantin and the Marony to the Dutch, retaining possession of the remainder.

GUYENNE or GUIENNE, and GASCOGNE, two provinces in the south-west of France, formed together the largest of the thirty-two military governments into which that country was divided previous to the revolution of 1792.

Gasconne, which nearly coincides with the Aquitania of Julius Cæsar, and the Novempopulana of Augustus, takes its name from the Gascones or Vascones, a Spanish people, who wrested it from the Franks in the beginning of the seventh century. It included the countries west of the Garonne, and is distinguished by the names of Couserans, Comminges, Bigorre, Armagnac, Condomois, Marsan, Landes, and Labour, and now forms the departments of Landes Gers, Hautes-Pyrénées, Haute-Garonne, and parts of Basses-Pyrénées, and Ariège, under which heads the particular features of the country are noticed. AUCH was its capital. From this province the Bay of Biscay is sometimes called the Gulf of Gasconne.

Guienne lay to the north of Gasconne, and extended from the Cévennes Mountains to the Bay of Biscay, including the districts of Rouergue, Quercy, Agenois, Périgord, Bazadois, and Bordelais. BORDEAUX was its capital. It now forms the departments of Gironde, Lot, Lot-et-Garonne, Dordogne, Aveyron, and part of Tarn-et-Garonne. The name is said to be a corruption of Aquitania, which designation was extended in the later divisions of Roman Gaul so as to include the districts northwards as far as the Loire. The entire government of Guienne and Gascony was sometimes spoken of under the name of Guienne.

The historical connection of Guienne and Gascony with the Plantagenet kings of England, is noticed under AQUITANIA.

The Gascons, though a very simple, industrious, and sober people, are generally represented as boasting exaggerators. This notion is supposed to have originated from the circumstance, that in former times the younger sons of Gascon families were compelled, in consequence of their poverty, to seek their fortunes as adventurers in other countries, where, in order to gain attentions, which their circumstances generally failed to command, they were wont to speak in hyperbolic language of the great valour and wealth of their ancestors, immediate and remote. Hence the term *gasconade* came to be equivalent to a harmless, amusing, and oftentimes highly comical vaunting.

GUY'S HOSPITAL, London, was built in the year 1724. The founder, Thomas Guy, was the son of a lighterman in Horsleydown, Southwark, and contrived, by a long career of industry and frugality, to amass a large fortune, which he devoted to works of charity and benevolence, besides making ample provision for the claims of consanguinity. He followed the occupation of a bookseller, and occupied as a place of business a house situated at the angle of Lombard Street and Cornhill, long since pulled down to make way for the improvements in front of the Mansion House. He was an alderman of the

city of London, and in this capacity took an active interest in its various charities, particularly in St. Thomas' and Christ's Hospital, both of which institutions he endowed liberally during his lifetime. He was also member of Parliament for the borough of Tamworth, and built and endowed numerous almshouses there for the benefit of his poorer relatives and friends. This charity is now under the management of the local magistracy. Many interesting anecdotes are related of Guy's domestic life, illustrative of his shrewdness of character, frugality, and practical benevolence. He was never married, but his relations appear, from his testamentary dispositions, to have been very numerous. For their immediate use he bequeathed 80,000*l.*, and gave their posterity a prior claim to the benefits of Christ's Hospital and the almshouses at Tamworth. But his largest bequest was the sum of 220,000*l.* for the endowment of the hospital which bears his name, and which he lived to see erected but not occupied—his death occurring at Christmas, 1724, a few weeks before the first patients were admitted to the wards. The hospital in Guy's time consisted only of two square blocks, which still exist. These were afterwards remodelled, and additions made to them, to accommodate 400 patients. By an act of incorporation, obtained shortly after Guy's death, the management of his estate was vested in the names of fifty gentlemen, who also became perpetual governors of the hospital. The residue of the property was profitably disposed of in the purchase of estates in Lincolnshire, Essex, and Herefordshire, which now yield an annual income of upwards of 35,000*l.* Thomas Hunt, another London merchant, residing at Petersham in Surrey, greatly improved the resources of the charity, by bequeathing, in 1829, the bulk of his property, amounting to 196,000*l.*, on condition that the governors should increase the accommodation by 100 additional beds. This has been done by the erection of a new hospital, which is now (1866) on the eve of completion, and which is intended to accommodate 300 patients. The chapel, placed in the front square of the hospital, contains a fine statue of the founder in marble, representing him in the act of pointing out to a suffering female the home he had furnished for her relief. There are also memorial windows in the chapel in acknowledgment of Hunt's bequest; and the governors have recently erected a tablet to the memory of Sir Astley Cooper, who was for thirty years surgeon to the hospital. The remains of Guy, Hunt, and Cooper, are placed in the vault underneath the chapel. The medical school of the hospital has long enjoyed a high reputation, on account of the distinguished names of its medical officers, among whom may be enumerated Sir Astley Cooper, Aston Key, Dr. Bright, and Dr. Addison. For some years past it has had the largest number of students enrolled of any of the Metropolitan medical schools. The average yearly number of patients admitted to the hospital is 5000, while the number of outpatients, including minor accidents, poor pregnant women, and others, has been annually increasing, and has latterly averaged upwards of 70,000 persons.

GUYTON, DE MORVEAU, LOUIS BERNARD, was born in 1737 at Dijon, in the University of which his father was professor of civil law.

In early life he showed a turn for mechanics, and after studying at home he went to college, which he quitted at sixteen years of age; he then became a law student, and acquired much skill in that profession. Having been admitted honorary member of the Academy of Dijon, the lectures he heard there gave him a taste for chemistry; and in 1772, having previously published some less important papers, he gave to the world a collection of scientific essays, entitled 'Digressions Académiques.' The memoirs contained in this work on phlogiston, solution, and crystallization merit particular notice, and evince the superior knowledge which he had acquired on the subjects that he had undertaken to illustrate. In 1773 he discovered the mode of destroying infection by the vapour of muriatic acid. In 1766 he commenced a course of well-attended lectures on chemistry at Dijon.

The fame of Morveau now began to extend to every part of Europe; and in 1767 he published the first volume of a course of chemistry, entitled 'Elémens de Chimie de l'Académie de Dijon.' The work was completed in four volumes, and was much admired. He afterwards supplied many articles to the 'Encyclopédie Méthodique.' He published a paper in the 'Journal de Physique' for 1782, to show the necessity of establishing a new and scientific chemical nomenclature.

On the breaking out of the French Revolution he became a decided friend to the popular cause, and was a member of the Convention and of the Council of Five Hundred. In 1799 Bonaparte appointed him one of the administrators-general of the mint, and in the year following director of the Polytechnic School; and after having been made one of the Legion of Honour he was created a baron of the French empire in 1811. At an advanced period of life he married, but left no children. After teaching about sixteen years in the Polytechnic School he gave up the appointment; and after about three years' retirement he died on 3rd January, 1816.

The publications of Morveau on chemical subjects are very numerous, and few of his contemporaries contributed more to the advancement of the science.

GUZERAT, or GUJERAT. [HINDUSTAN.]

GWALIOR, a principality in Central India, is a fragment of the great empire of the Peishwa, and has been under British protection since 1803. In 1843, the death of the sovereign caused universal anarchy, and led to the forcible interposition of the British government, and since that time some of our troops have been stationed there, in addition to about 9000 native soldiers. During the mutiny of 1857, the young Maharajah remained faithful to the English, though the troops rebelled. The population of the state is estimated at 3,250,000. The chief towns are:—

Gwalior, the capital, about sixty miles south of Agra, has a population of 50,000, grouped around a rock-fortress of remarkable strength, which rises almost perpendicularly to a height of 300 feet, and is completely isolated. The summit is crowned by a citadel, which can accommodate a garrison of 15,000 men, and is provided with large tanks of water. It is impregnable to native troops. But the revolt of the garrison in 1857 placed it in the hands of the rebels, and it was a centre of rebellion for more than

a year, when it was recovered by Sir Hugh Rose. *Jhansi* is a fortified town on the south of Gwalior, with considerable trade and a large population. All the Europeans, men, women, and children, fell by the hands of the native troops in 1857, not one being left alive to tell the story of their fate. The town was taken by storm in the following year by Sir Hugh Rose, after a desperate defence.

Oojein, or *Ujein*, an ancient capital, in a southern part of the country, contains 130,000 inhabitants, and has many mosques and temples, with extensive trade. It is one of the seven sacred cities of the Hindus.—(Milner's *Gallery of Geography*, 1864.)

GWILT, GEORGE, an eminent architect and antiquary, was born in the county of Surrey in 1775. He was the son of George Gwilt, an architect of some celebrity, who erected the Newington Sessions House, Horsemonger Lane Gaol, and many other public edifices in the locality. The professional knowledge of the son was chiefly obtained in the office of his father, whom he succeeded in business. At a very early age he displayed considerable taste for antiquities, which eventually introduced him to an extensive connection. In 1815 he became a fellow of the Society of Antiquaries, and in 1818 he was engaged upon the restoration of the steeple of Bow Church, a work which required considerable skill and knowledge of ancient architectural details. In 1822 he undertook the restoration of the tower and choir, and afterwards of the lady chapel, of St. Mary Overy's Church, in Southwark, which are considered as among the most interesting works of art in the Metropolis. He died in 1856, at the advanced age of eighty-one.

GWYNN, JOHN, R.A., architect, was born at Shrewsbury in the early part of the eighteenth century. Gwynn erected a church and some other buildings, but is remembered on account of his bridges and his writings. He built the well-known Magdalen Bridge at Oxford; and the picturesque, but not very convenient, English bridge at Shrewsbury. He also competed for the erection of Blackfriars' Bridge, London, and carried on a brisk controversy (assisted by Dr. Johnson) with Mylne, whose design was selected. As a writer Gwynn has the merit of having suggested various important public improvements, which, though neglected at the time, have since been to a remarkable extent adopted. In 1749 he published 'An Essay on Design, including Proposals for erecting a Public Academy.' This was to be an English academy of painting, sculpture, and architecture; and when, nineteen years later, the Royal Academy was founded, Gwynn's suggestions were to a considerable extent followed. Gwynn was one of the original members of the Royal Academy. His most remarkable work was a quarto volume, which appeared in 1766 under the title of 'London and Westminster Improved,' and for which Johnson wrote a dedication to the king. In this Gwynn not only proposed to replace old London Bridge by a new one, and to erect another bridge almost on the exact spot long afterwards selected for Waterloo Bridge; to widen the Strand, and other main thoroughfares; to form open central spaces, and to construct a great number of new streets, which should more directly connect the various public places and centres of business;

VOL. VII.

but also to embank the Thames between the bridges, and to form a river-side road one hundred or one hundred and twenty feet wide, half being devoted to quays, and half to a carriage way; to improve the sewers, and to remove the burial-places to a convenient distance outside the city. In this work, strange to say, a very large proportion of the chief improvements which have only within the last few years been made in the Metropolis, and many which sanitary reformers and others are still vainly urging, were not merely indicated by him, but clearly explained in maps, as well as in descriptions. Gwynn had spent many years in elaborating his plans, he having, as he states in an introduction, first proposed a less comprehensive scheme (founded on Wren's plan for the rebuilding of London) seventeen years before. His projects seem, however, to have been regarded as visionary, and to have been long utterly neglected. Within the last few years attention has been directed to them; but Gwynn himself has hitherto not found a place in any biographical dictionary, English or foreign, and it is with some difficulty we have found the materials for this scanty notice. We cannot ascertain the exact date of his death; but as a new academician was elected in his place in October, 1786, there can be little doubt that it occurred in that year.—(*Imp. Dict. of Universal Biography*, Mackenzie, 1866.)

GY'AROS, one of the smaller Cyclades, situated nearly at an equal distance between Andros, Ceos, and Syros. It is about four miles long, and three miles in its greatest breadth, and is rocky and barren. It is now called Ghioura, and is not inhabited, except occasionally by fishermen. Under the Roman emperors it was used as a place of banishment.

GYGES. [LYDIA.]

GYMNADE'NIA, a genus of plants belonging to the natural order *Orchidaceæ* and the tribe *Ophrydineæ*. There are two British species, *G. conopsea* and *G. albidæ*. They are found in mountainous and hilly pastures, and blossom in June and July.

GYMNAPISTES (γυμνός, 'bare,' or 'naked,' and ἀπιστος, 'treacherous'), a genus of fishes of the family *Scorpenidae*, whose bodies are naked, and the anal fins furnished with three strong spiny rays.

GYMNARCHUS (Gr. γυμνός, 'bare,' and ἄρχης, 'head'), a genus of fishes of the eel kind, and of the family *Sternarchidae*.

GYMNASTICS, or more properly *gymnastic* (γυμναστική, from the word γυμνός, 'naked,' it being customary among the Greeks to strip themselves, wholly or in part, before engaging in bodily exercises). Gymnastic games may be said to be prehistoric; they are mentioned in the second and twenty-third books of the 'Iliad.' The rewards given to the conquerors in these games were called *athla*, which gave origin to the word athlete, as applied to those who contended for them. Before the time of Hippocrates gymnastics were made a part of medicine, as a means of counteracting the bad effects of increasing luxury and indolence. The various exercises were gradually reduced into a complete system: public buildings called *Gymnasia* were erected for the purpose, and superintending officers appointed by the state.

The first gymnasia were built by the Lacedæmonians (Plato, *Nóμοι*, lib. i.), and after them by

D

the Athenians. Those built by the Romans were on a more magnificent scale, and from the extensive baths which were attached to them are not unfrequently called *Thermæ*.

The exercises practised in the gymnasia were—dancing, wrestling, boxing, running, leaping, quoits, and hurling the javelin or some similar instrument. Since the introduction of gunpowder, science and skill have had more to do with warfare than mere strength of muscle, and consequently gymnastics went out of repute in military life, and were soon little thought of in civil life. During the present century, however, the practice has revived, and in Prussia, Sweden, France, and England, is daily gaining more attention and improvement.

In the English army recruits have to undergo daily gymnastic training for two months instead of musketry instruction. Young officers, while at recruit, drill the same. Weak and awkward men are kept at it for six months. As soon as they have passed all the courses of gymnastic exercise, it is left optional with them to further improve themselves by voluntary practice. The object aimed at is to harden and strengthen the trained soldier, so as to enable him to cover 1000 or more yards of ground at a rapid pace, and leave him in good wind, and able to use his bayonet efficiently. A medical inspection of the recruits is made at the gymnasium once a fortnight, and of the trained soldiers once a month. The men are also measured and weighed at stated periods, in order to observe the progress made in developing muscle, height, breadth of chest, and weight. The cavalry officers and privates have to go through a course of fencing drill; and swimming is also taught at all stations where facilities for it exist.

The principle on which gymnastic exercises act is evident; their immediate effect is an increase both in the size and power of the parts exercised, in consequence of an admirable law which obtains in living bodies, that (within certain limits), in proportion to the exertion which it is required to make, a part increases not only in strength and fitness, but also in size. Instances of the application of this law may be seen daily. A person is called on to engage in some new avocation, in which muscular exertion is required, and every day he is not only improved in strength and dexterity, but the muscles brought into unusual action increase rapidly in size and vigour, so as soon to surpass those of the rest of the body which have been less employed. Nor does the beneficial influence stop here. If the exertion be not carried so far as to produce excessive fatigue, all other parts of the body sympathize with the improving condition of that which is chiefly exerted; the circulation, being excited from time to time by the exercise, acquires new vigour, and, the blood being thrown with unusual force into all parts of the system, all the functions are carried on with increased activity. Improvement in the general health is soon manifested; and the mind, if at the same time judiciously cultivated, acquires strength, and is rendered more capable of prolonged exertion. As instances of the bad effects of a deficiency of exercise, it will be sufficient merely to allude to the condition of those who, being compelled to a sedentary occupation during the greater part of the day,

neglect to occupy a part of their leisure time in some active exertion, as walking, riding, &c.

Excessive exercise, on the other hand, should be carefully avoided; for, though less frequent, instances are not uncommon where undue exertion has produced effects scarcely less injurious than those which result from inactivity. The existence of either class of evils is sufficient to prove that gymnastics should form a part of the education of youth, as much as 'literary instruction, music, and the art of design,' which with 'gymnastic' are mentioned by Aristotle ('Polit.,' lib. viii.) as the four branches of instruction recognized in his day. In order that gymnastics may produce their proper results, some general system should be established in all schools, by which one sex may be preserved from the evils of deficiency, and the other from those of excess in exertion; and the beneficial influences which gymnastics exercise on the mind as well as on the body may thus be secured to both.

Gymnastics, properly so called, are simple exercises, whose primary and direct aim is muscular development and health. They should commence with elementary and special movements, with a view to render every part of the body supple, and proceed to the exercises of leaping, suspension, standing and walking on beams, walking on stilts, climbing, swinging, vaulting, &c. The games that bring the greater number of muscles into successive or harmonious play are the best to strengthen the system during infancy and adolescence, and to maintain it in vigour and health during manhood. A few of the most appropriate are, cricket, foot-ball, rackets, tennis, golf, battledore and shuttlecock, dancing, rowing, skating, climbing, and swimming. Reading aloud and singing are also admirable agents in expanding the chest.

GYMNE'MA (Gr. *γυμνός*, 'bare,' and *νημα*, 'a thread,' in reference to the stamens), a genus of twining shrubs, of the order *Asclepiadaceæ*. There are many different species which possess a variety of uses; for instance, *G. tingens*, of the East Indies, produces indigo of a most excellent quality. From the *G. lactiferum* of Ceylon a milky juice is exuded, which, together with the boiled leaves, is used by the Cingalese for food. The leaves of the *G. sylvestre*, when chewed, have the singular property of taking away the power of tasting sugar for twenty-four hours, without otherwise injuring the general sense of taste.

GYMNETES (Gr. *nakedness*), a genus of the family *Gymnetres* or Ribbon-fishes, with thin bodies and long ventral fins.

GYMNOCANTHUS (Gr. *γυμνός*, and *ἀκανθα*, 'a spine'), a genus of fishes, of the family *Cottidæ*, or Bull-heads; the head naked, and the ventral fins very long.

GYMNO'CLADUS, a genus of plants belonging to the natural order *Leguminosæ*. There is but one species, *G. Canadensis*, the Kentucky Coffee-tree. The branches of this tree are without any appearance of buds, which, during the winter, gives it the aspect of a dead tree, and hence the Canadian name Stump-tree. The wood is hard, compact, and of a fine rose colour. In America it is used in cabinet-making and carpentry. It has the property of rapidly converting its sap-wood into heart-wood, so

that the smallest trees may be applied to useful purposes. This tree grows well in Great Britain, but does not ripen its seeds.

GYM'NOGENS (Gr. *γυμνός*, and *γεννέω*, 'to bring forth'), an order of plants comprising (according to Lindley) the natural orders *Cycadaceæ*, *Pinaceæ*, *Tazaceæ*, and *Gnetaceæ*, or Joint-firs.

In Zoology and Botany, the word *gymnos*, denoting 'bareness,' or 'nakedness,' is extensively used as a compound in the formation of numerous scientific terms. Thus *Gymnocephalus*, 'bare-headed,' in zoology, is a genus of birds belonging to the Coraciæ, or Fruit-crows, commonly called Bald-tyrants; *Gymnodactylos*, 'bare-fingered,' is a genus of Saurian reptiles belonging to the Gecko family; *Gymnodontes*, 'naked-toothed,' is a term applied to a family of malacopterygious fishes, of the order Plectognathes, whose jaws, instead of teeth, are furnished with a smooth ivory substance; *Gymnogaster*, 'bare-bellied,' is a genus of fishes of the tribe Gymnetres, or Ribbon-fishes; *Gymnomyza*, 'naked fly,' a genus of dipterous insects of the Muscidæ tribe; *Gymnophryx*, 'naked eyebrow,' a genus of birds of the Meliphagidæ family, or Honey-sucker; *Gymnopleurus*, 'bare-ribbed,' is a genus of coleopterous insects of the family Scarabeidæ; *Gymnosoma*, 'bare-bodied,' a genus of the order Aporobranchiata, which have no shells; *Gymnotus*, 'bare-backed,' is a genus of apodal fishes, with eel-shaped bodies; *Gymnure*, 'bare-tailed,' is a genus of animals of the digitigrade tribe; *Gymnandra*, 'naked male,' in botany, is a genus of glabrous shrubs, of the order Scrophulariaceæ; *Gymnanthera*, 'naked anther,' is a genus of plants of the order Asclepiadaceæ; *Gymnocarpus*, 'naked fruit,' is a genus of shrubby plants, of the order Illicebraceæ; *Gymnogramma*, 'bare characters,' is a genus of ferns, of the order Polypodiaceæ; *Gymnosperma*, 'naked seed,' is a genus of composite plants, of the sub-order Tubulifloræ; *Gymnostachys*, 'naked spike,' is a genus of leguminous plants, of the sub-order Papilionaceæ, natives of New Holland.

GYMNO'PS, a genus of birds (*Goulin*) established by Cuvier, and described by him as having a bill as strong as that of the Orioles, the nostrils round, without scales or any membranous *entourage*, and a great part of the head denuded of feathers. He refers to *Gracula calva*, Gmel., *Mino Dumontii*, Less., and *Gracula cyanotis*, Lath. (*Merops cyanotis*, Sh.), as examples.

GYMNO'SOPHISTS (Gr. *γυμνός*, 'naked,' and *σοφιστής*, 'a sophist'), a sect of Indian philosophers, frequently mentioned by the Greek writers, and so called from their habit of going almost naked. Their manners and habits were not unlike the Cynics of the Greeks, as personified by Diogenes. They were frequently consulted by the highest personages in cases of difficulty or importance; and great reliance was reposed in them. They would not, however, wait upon their inquirers, but obliged them to send their messages, or to come themselves. They lived upon the natural productions of the earth without culture, and did not form themselves into societies, as other sects did; but each one had his particular place of retirement, where he studied in solitude, and performed his devotions. They were very strict in their frequent examinations of their disciples, or scholars, in order to ascertain the improvements

they had made in the different branches of learning, or the especial virtues or good deeds they had practised since the previous examination. They believed in the immortality of the soul, and its migration into different bodies. The Gymnosophists are mentioned and particularly described by Diogenes Laërtius. According to Jerome and Clemens, their great leader was one Buddas, or Butta; but Suidas classes him among the Brachmans, from whom the modern Brahmins have doubtless originated.

GYMNOSPERMS, one of the five divisions under which the vegetable kingdom is now classified. The name is derived from the seeds being naked, that is to say, unprotected by a pericarpial covering, and fertilized by the pollen coming in direct contact with the ovule, not by the intervention of the apparatus called stigma and style. In this respect Gymnosperms are analogous to those reptiles which, in the animal kingdom, have eggs that are impregnated by the male after they have been deposited by the mother.

The number of plants in which this peculiarity exists is inconsiderable; they entirely belong to the natural orders, *Conifera* in its most extensive sense, and *Cycadaceæ*. *Equisetaceæ* perhaps have to be added, but this is a point at present involved in doubt.

In their manner of growth Gymnosperms correspond on the one hand with Exogens, the wood of *Conifera* being arranged in concentric circles, and on the other with Endogens, the wood of *Cycadaceæ* being very nearly like that of a palm-tree. In fact, the class of Gymnosperms may be considered to unite the two classes of Exogens and Endogens so perfectly that not a link remains to be supplied. They also closely border upon Acrogens, of which *Cycadaceæ* have the gyrate venation, *Conifera* the veining, and in some cases the peculiar arrangement of the male apparatus.

In addition to the differential characters of these plants, we have to add that their sexes are always separate, and that their leaves, if furnished with veins at all, have them parallel as in Endogens, or forked as in ferns, and never reticulated as in the class of Exogens.

GYMNO'TUS, a genus of fishes of the section *Apodes*. Generic characters:—Gills partially closed by a membrane, and opening before the pectorals; the vent placed very far forwards; body without any perceptible scales, and without dorsal fin; anal fin extending the greater part of the length of the body.

Gymnotus electricus (Linn.), from the resemblance it bears to an eel, and the electric power which it possesses, has been called the Electric Eel. It is about five or six feet in length; the head is rather broad and depressed; the muzzle is obtuse; the body, compared with that of the common eel, is stouter and shorter in proportion; the anterior part is nearly cylindrical, but towards and at the tail it is compressed; the pectoral fins are small and rounded; the anal fin commences at a short distance behind the line of the pectoral fins, and extends uninterruptedly to the tail; there is no caudal fin. Its colour is brownish black.

The Electric Eel is said to communicate shocks so violent that men, and even horses, are overpowered by them. This power is dependent on the will of the animal, but decreases in strength if frequently

repeated, unless at considerable intervals. The organs by which this shock is produced are minutely described by Hunter in the sixty-fifth volume of the 'Philosophical Transactions.' All the species of *Gymnotus* inhabit the rivers of South America.

The genus *Cerapus* of Cuvier contains such species of *Gymnotus* of the older authors as have the tail lengthened and tapering, and the body compressed and furnished with scales. They also inhabit South America.

GYMNU'RA, a genus belonging to the order *Insectivora*, and established by Dr. Horsfield and Mr. Vigors for the reception of an animal brought from Sumatra, and first introduced to science by Sir Stamford Raffles, who described it under the title of *Viverra Gymnura*. Cuvier (vol. i. 'Add. et Corr.') observes that it appears to approach *Cladobates* (*Tapia*, Raffl.) in its teeth, and the Shrews in its muzzle and scaly tail. The feet (plantigrade) are each furnished with five toes; the eyes are small; the whiskers long. The fur consists of a short dense woolly undercoat and of long coarse thinly set hairs.

Example, *Gymnura Raflesii*.—This animal has the body, feet, stripe above the eyes, scattered occipital hairs, and the basal half of the tail, black; the head, the neck, the scattered hairs of the back, and the other half of the tail, white. (Horsfield and Vigors.) Length of head and body (adult) 1 foot 2 inches, of the tail 10½ inches. Habits unknown; exhales a strong musky smell. Original specimens in the Museum of the Zoological Society.

GYNA'NDRIA, one of the classes in the artificial system of botany invented by Linnaeus.

GYNE'CIUM (Gr. *gynè*, 'a woman,' and *oikos*, 'a dwelling'), among the ancient Greeks a room set apart for the women, who were occupied with operations of the needle or the loom, or other domestic duties. Among the Romans it was a depôt for clothes or furniture, where females were constantly at work. In the Middle Age, the term was also applied to any private apartment in the house or mansion, where the women were in the habit of making clothes, or preparing the needle-work furniture of the household.

GYNOCH'THODES (Gr. *gynè*, 'a female,' and *ochthos*, 'a wart'), a genus of plants, of the order *Cinchonaceae*, natives of Japan.

In Botany, there are many genera of plants compounded of the word *gynè*, 'a female,' in allusion to the pistil of the flower; as *Gynopachys*, 'thick pistil,' a genus of climbing shrubs, of the same order and country as the above; *Gynophore*, 'a bearing female, or pistil,' a term applying to the receptacle of a flower having the petals, stamens, and pistil, but not the calyx; *Gynostemma*, 'a crowned female,' a genus of climbing shrubs, of the order *Memispermaceae*, natives of Java, and so named from the ovaries being crowned by the permanent stigmas.

GYPA'ETOS, Storr's generic name for the Lämmergeyer, or Bearded Griffin (*Gypaëtos barbatus*), a bird of prey which may be considered as intermediate between the eagles and the vultures. [VULTURIDÆ.]

GYPOGE'RANUS, Illiger's generic name for the Secretary Bird, which some have placed with the gallinaceous tribe, others among the wading birds, and others again among the vultures. We agree with those who regard it as one of the aberrant

forms of the *Falconidæ*, destined for terrestrial habits, and for feeding on reptiles and small quadrupeds.

Generic Character.—Bill rather slender, shorter than the head, strong, very much hooked, curved nearly from its origin, and furnished with a cere at its base, rather vaulted, compressed at the point; nostrils placed at a small distance from the base, lateral, pierced in the cere, diagonal, oblong, open. Feet very long, slender, the tibia feathered behind, but not quite to what is called (improperly) the knee, whilst the feathers come a very little below the joint before; tarsus long, more slender below than in its upper part; toes short, warty below, the anterior

Secretary Bird (*Gypoggeranus serpentarius*).

toes united at the base by a membrane; hind toe articulated upon the tarsus. Wings long, armed with obtuse spurs; the five first quills the longest and nearly equal. Locality Africa; the Philippines.

Sparman, Le Vaillant, Smith, and others, have described at length the habits and manners of this singular and most useful bird, at considerable length; and to the works of these travellers we refer our readers. Their details relate to the Cape species (*G. serpentarius* of authors, *G. capensis*, Ogilby). It inhabits arid plains, and destroys great numbers of serpents, often not without a severe conflict. Quervoert, as quoted by Le Vaillant, says:—'In descending from a mountain into a very deep bog (fondrière), I perceived, nearly perpendicularly below me, a bird which raised and lowered itself very rapidly, with very extraordinary motions. Although I well knew the secretary, and had killed many of these birds at Natal, it was impossible for me to recognize it in the vertical situation in which I found myself, and I only suspected that it was one from its bearing. Having found means, by favour of some rocks, to approach sufficiently near, noiselessly and without being discovered, I found that this bird was a secretary combating a serpent. The fight was very sharp on both sides, and the skill (la ruse) equal on the

part of each of the combatants. But the serpent, which perceived the inequality of its strength, employed that adroit cunning which is attributed to it, in order to save itself by flight and regain its hole; while the bird, divining its intention, stopped it at once, and, throwing itself before the serpent by one spring, cut off its retreat. Wherever the reptile essayed to escape, there it always found its enemy. Then, uniting skill with courage, it erected itself fiercely to intimidate the bird, and presented, with a frightful hiss, a menacing gape, inflamed eyes, and a head swollen with rage and poison.

'Sometimes this offensive resistance suspended hostilities for an instant; but the bird soon returned to the charge, and covering its body with one of its wings, as with a shield, struck its enemy with the other, with the bony protuberances of which I have already spoken, and which, like small clubs, overpowered it the more surely, inasmuch as it presented itself to the blows. In effect, I saw it reel and fall extended: then the conqueror threw himself upon it to finish his work, and with one blow of the bill split its skull.

'At this moment, having no further observations to make, I killed it. I found in its crop (for it has one, which nobody has stated), on dissecting it, eleven rather large lizards, three serpents as long as one's arm, eleven small tortoises very entire, many of which were about two inches in diameter; and, finally, a quantity of locusts (*sauterelles*) and insects, the greater part of which were sufficiently whole to deserve being collected and to be added to my specimens. The lizards, the serpents, and the tortoises, had all received the stroke of the bill upon the head.'

According to Lesson, attempts have been made to introduce the breed into the French sugar islands (Martinique, &c.), in the hope that it might diminish the race of the formidable *Trigonocephalus*, the yellow serpent of the Antilles (*Trigonocephalus lancoletus*, Opp.), the most dangerous reptile of those parts, six or seven feet in length, and rivalling the rattlesnake in the intensity of its poison.

The secretary bird is about three feet in length; it lives in pairs and builds upon high trees, sometimes in dense thickets; it is very wary, and runs with considerable swiftness. Plumage, when perfect, for the most part bluish-grey, with a reddish-brown tinge on the wings; greater quills black. Throat and breast nearly white; rest of the under surface black, reddish, and white intermingled, the plumage of the legs bright black, with a slight intermixture of brownish rays. Occipital crest, which can be raised or depressed at pleasure, consisting of feathers without barbs at the base, but spreading out as they advance, and coloured of a mixed black and grey. Eyes surrounded by a naked skin, full, and over-

shadowed with hairs in the form of an eye-brow; eyelashes long and strong.

GYPSUM, or sulphate of lime, is a mineral which is found in a compact and crystallized state, as alabaster [ALABASTER] and selenite, or in the form of a soft chalky stone, which in a very moderate heat gives out its water of crystallization, and becomes a very fine white powder extensively used under the name of Plaster of Paris. In 1863 the quantity of gypsum imported into the United Kingdom was 3015 tons, value 3826*l.*, of which quantity only two tons were exported. [CALCIUM; MANURE.]

GYR-FALCON, or JERFALCON. [FALCONIDÆ.]

GYRACANTHUS, a genus of fossil placoid fishes, from the mountain limestone and coal strata: four British species. (Agassiz.)

GYRATION, CENTRE OF. When a system of heavy bodies, or any system possessing weight, has a fixed axis of revolution, the centre of gyration is a point at any such distance from the axis, that the moment of inertia would not be altered if the whole mass were collected at that point.

GYRINIDÆ (Gr. *gyros*, 'a circle'), a family of coleopterous insects (the Water-beetles, or Whirligigs), of which *Gyrinus* is the type. They are so called from their habit of swimming in circles on the surface of the water; and the velocity with which they execute their evolutions is really surprising. The French have given them the name of *Tournequets*.

GYROCARPUS, a genus of plants containing few species, but these few are widely distributed in Asia and America. The Asiatic species grows to be a large tree, with cordate leaves, which are deciduous about the end of the rainy season; after which the flowers make their appearance in the cold weather, but are shortly followed by the new leaves. The wood of this tree is whitish-coloured and very light. It is preferred whenever procurable for making the catamarans, or rafts, on which the natives come off to ships through the heavy surf of the Madras coast.

GYRODUS, a genus of fossil ganoid fishes from the oolite and cretaceous strata chiefly: ten British species. (Agassiz.)

GYROLÆPIS (Gr. *gyros*, and *lepis*, 'a scale'), a genus of fossil fishes, whose remains occur in the bone-beds of the lias formation, and also in the new red sandstone.

GYRONCHUS (Gr. *gyros*, and *onux*, 'a nail'), a genus of fossil ganoid fishes, from the oolite of Stonefield. (Craig.)

GYROPRISTES (Gr. *gyros*, and *pristēs*, 'a saw'), a genus of fossil placoid fishes, from the new red sandstone.

GYROSTEUS (Gr. *gyros*, and *ostēon*, 'a bone'), a genus of fossil ganoid fishes found in the lias formation.

H.

H is an aspirate of the guttural series, and is a faint pronunciation of the sound which in the High German alphabet is denoted by *ch*. In the earliest alphabets, as the Greek and Hebrew, the symbol whence the modern character is derived denoted the syllable *che* or *he*. Hence the Hebrew name was *cheth* or *heth*; and the Greek probably at first *heta*, as it was afterwards *eta*. As the guttural sound disappeared in the latter language, the letter finally denoted the simple vowel *ē*. In the Latin alphabet it was retained as the symbol of the aspirate. The English name *aitch* was probably at first *ech*, with the vowel prefixed, as in *ef*, *el*, &c. The guttural sound of *ch* is often confounded with the sibilant *ch*, as heard in *church*.

The letter *h* is liable to the following changes in different dialects:—

1. *H* is interchangeable with *c* [see C, 3]. To the examples there given may be added the Latin *decem* compared with the German *zehn*.

2. *H* is interchangeable with *ch*. Thus the Greek forms *χημων*, *χημαρινος*, *χημαι*, are severally connected with the Latin *hiems*, *hibernus*, *humi*.

3. *H* with *chth*. Of the interchange between the aspirates there are examples in the Greek *χθες* compared with the Latin root *hes* in *heri* and *hesternus*.

4. *H* is interchangeable with *g*. Examples: the German *zehe* compared with the Latin *digito*; the German *fliehen*, *sehen*, compared with the English substantives *flight*, *sight*.

5. *H* with *s*. Compare the Latin *sub*, *sex*, *septem*, *sus*, with the Greek *ὑπο*, *ἕξ*, *ἑπτα*, *ὑς*.

6. *H* with *f*. Hence the Latin words *hostis*, *hostia*, says Festus, were sometimes written *fostis*, *fostia*. The French word *hors* is derived from the Latin *foris*. The Spanish language abounds in examples of this change, as in *hermoso*, from the Latin *formoso*; the Portuguese retains the form *formoso*. [F.]

7. *H* with *w*. Many Greek words which had originally the digamma (another name for the letter *w*) at the beginning, took a mere aspirate afterwards. In English the word *who* has nearly exchanged the *w* for what is sounded as an *h*; and the relative adverb *how* is no doubt derived from the relative itself.

8. When any consonant or consonants in the middle of words had nearly lost all sound, the letter *h* appears to have been employed as a representative of the vanishing sound. Hence in Latin *mihi*, for what would appear by analogy to have been once *mibi*; and in German *stehen* and *gehen*, for what must have been *standen* and *gangen*.

9. The letter *h* is often dropped altogether in pronunciation, and hence in writing also. In Latin many words are written indifferently with or without

HAARLEM.

an *h*, as *arena*, *harena*; *onustus*, *honustus*. The Italians for the most part are averse to all aspirates; but the people of Tuscany still maintain their ancient character for the strongest pronunciation of these harsh sounds.

HAARLEM, **HAERLEM**, or **HARLEM**, a city in the Dutch province of North Holland, stands on the Spaaren, which runs from the Lake of Haarlem into the Y, four miles from the shore of the North Sea, in 52° 23' N. lat., 4° 38' E. long., and had in 1862, 29,426 inhabitants. It is connected by canals with all the principal towns in Holland, and by railway with Amsterdam and Leyden, from which it is respectively 12 and 13 miles. Haarlem is famous for its resistance to the Spaniards in 1572, and for the cruel treatment of its citizens by the son of the duke of Alva after their surrender. The town is well built; the streets are clean, planted with trees, and traversed by numerous canals. It contains several Roman Catholic churches, one of which, the cathedral of St. Bavon, is the largest church in Holland, and celebrated for its great organ, which has 5000 pipes, sixty stops, and four rows of keys. It was built in the fifteenth century, and, until recently, was the largest in the world. There are also Calvinistic and Lutheran churches. The finest building in the town is the Stadhuis, or town-house, which stands on one side of the market-place. The Prinzenhof, in which the States-general of Holland formerly met, is now converted into a museum of arts, antiquities, medals, and pictures. The public walks on the site of the ancient ramparts are exceedingly agreeable. Haarlem, besides many benevolent institutions, has numerous public schools, an academy of sciences, a botanic garden, a public library, a national normal school for schoolmasters, and the Teyler institution, which comprehends an establishment for the poor, a society of natural history, valuable collections, and an observatory. The library boasts of the early productions of Laurence Coster, a native of this town, for whom the Dutch claim the invention of the art of printing. [COSTER.] The neighbourhood of the town is studded with handsome country seats, and laid out in gardens. In the southern suburb of Haarlem are the famous nursery flower-gardens, in which are raised the flowers and flower-seeds, which form such important articles of Dutch commerce. Haarlem is the centre of the trade. They consist principally of hyacinths, tulips, and other bulbs. There are extensive bleaching establishments here, which formerly supplied large quantities of linen to England, whence the article came to get the name of *Holland*, as coming from that country. Silk, carpets, ribands, lace, and soap, are among the principal manufactures.

The Lake of Haarlem, which lies S.E. of the town,

is 14 miles long, 10 broad, and 14 feet deep, between water and mud. The mud of the lake is manufactured into valuable bricks called clinkers. The lake has been drained, and it is calculated that 45,000 acres of land have thus been gained.

HAARLINGEN. [FRIESLAND.]

HABAKKUK, one of the twelve minor Hebrew prophets. We have no particulars respecting the place and time of his birth; but it appears probable that he prophesied in the beginning of the reign of Jehoiakim (B.C. 609). The prophecy of Habakkuk is written in an energetic style, and contains many beautiful passages. The third chapter is considered by Bishop Lowth as one of the finest specimens we possess of the Hebrew ode. The canonical authority of the book has never been disputed. It is quoted in the New Testament: compare Hab. ii. 4 with Rom. i. 17, Gal. iii. 11, and Heb. x. 38; and Hab. i. 5 with Acts xiii. 40, 41.

HABEAS CORPUS is a writ at the common law, used for various purposes. It derives its name, like other writs, from the formal words contained in it. When the writ of Habeas Corpus is spoken of without further explanation, it always means the important writ which will presently be described; but it is also used for certain purposes in the courts of common law at Westminster, as for removing prisoners from one court into another, and for compelling the attendance of prisoners as witnesses, &c. But the great writ of Habeas Corpus is that which in cases of alleged illegal confinement is directed to the person who detains another; and the purport of the writ is a command to such person to produce the body of the prisoner, and to state the day and the cause of his caption and detention, and further to do, submit to, and receive (*ad faciendum, subjiciendum, et recipiendum*) whatsoever the judge or court that awards the writ shall direct.

All persons, whether natives or aliens, are entitled to this writ. The statute 31 Car. II. c. 2, which is called the Habeas Corpus Act, declares the cases and mode in which this writ may be obtained; and, lest this statute should be evaded by demanding unreasonable bail or sureties for the prisoner's appearance, it is declared by the 1 Wm. and Mary, stat. ii. c. 2, that excessive bail shall not be required. The provisions of the 31 Car. II. c. 2, are extended to Ireland by the Irish act, 21 & 22 Geo. III. c. 11.

It has been customary in times of alleged danger to suspend the Habeas Corpus Act. A suspension of the Habeas Corpus Act is effected by an act of Parliament, which empowers the crown, for a limited period, to imprison suspected persons without stating any reason for the imprisonment. 'The effect of a suspension of the Habeas Corpus Act is not in itself to enable any one "to imprison suspected persons without giving any reason for so doing." But it prevents persons who are committed upon certain charges from being bailed, tried, or discharged, for the time of the suspension, except under the provisions of the suspending act, leaving, however, to the magistrate or person committing all the responsibility attending an illegal imprisonment. It is very common, therefore, to pass acts of indemnity subsequently, for the protection of those who either could not defend themselves without making improper disclosures of the information on which they acted,

or who have done acts not strictly defensible at law, though justified by the necessity of the moment. See 57 Geo. III. c. 3 and c. 55, for instances of suspending acts; and 58 Geo. II. c. 6, for one of an indemnifying act.'

The 56 Geo. III. c. 100, which was passed 'for more effectually securing the liberty of the subject,' after reciting that the existing acts only apply to cases of imprisonment on criminal charges, enacts that, if any person is imprisoned, except for crime or debt, any baron of the exchequer, as well as any judge of either bench in England or Ireland, shall, on complaint on behalf of the party confined, if reasonable cause appear to them, award in vacation time a writ of Habeas Corpus, returnable immediately before the judge awarding the same, or any other judge of the same court.

The statute 31 Car. II. c. 2, introduced no new principle into the English law. From the date of the Great Charter at least, if a man was confined in prison on a criminal charge, he could apply to the court of King's Bench for the writ of Habeas Corpus *ad subjiciendum*. This writ could not be refused. The object of the statute of Charles was to prevent the abuses which had grown up to the detriment of this important privilege.

Habeas Corpus is not a form known in the law of Scotland. The form by which a person imprisoned gets his trial brought on, or his release if he is not brought to trial, is there called 'Running Letters.'

HABENARIA, a genus of plants belonging to the natural order *Orchidæ*. There are three species natives of Great Britain. *Habenaria viridis*, the Frog Orchis, is the *Peristylus* of Lindley, and the *Himantoglossum* of Reichenbach. It grows in pastures. *H. bifolia*, the Lesser Butterfly Orchis, has white flowers. It is found in heathy places. *H. chlorantha*, the Great Butterfly Orchis, grows in moist woods and thickets.

HABERDASHERY technically comprises small ware composed of various descriptions of articles, such as of cottons, woollens, linens, muslins, silks, &c., and forms a large article of export from the United Kingdom. The quantity exported in 1863. (not including embroidery or millinery), was valued at 3,298,244*l.* The largest markets were Australia, 623,824*l.*; United States, 545,562*l.*; British North America, 497,643*l.*; India, 168,807*l.*; France, 154,145*l.*; and Egypt, 93,779*l.* The whole of the haberdashery exported was of British and Irish manufacture.

HABERE FACIAS POSSESSIONEM, a judicial writ directed to the sheriff, commanding him to put the recoverer of a chattel interest in lands into possession.

HABERE FACIAS SEISINAM, a judicial writ directed to the sheriff, commanding him to put the recoverer of a freehold interest in lands into possession. In the execution of this writ, as well as of the writ of *Habere facias Possessionem*, the sheriff may justify breaking open doors if the possession be not quietly delivered up.

HABINGTON, WILLIAM, the son of Thomas Habington, a Roman Catholic gentleman of family and fortune in Worcestershire. His mother, the daughter of Lord Morley, has been supposed to have been the writer of the famous letter which revealed

the Gunpowder Plot. [FAWKES, GUIDO.] Habington was born upon the very day now marked as the date of the plot, the 5th of November, 1605. He was educated in the Jesuit college of St. Omer, and afterwards at Paris; and endeavours were used, but in vain, to induce him to enter the society. He married Lucy, daughter of William Herbert, the first Lord Powis. He died at Hindlip on the 13th of November, 1645, when he had just completed his fortieth year. His published writings were the following:—1. 'Castara,' a collection of poems, first printed together in 1635. 2. 'The Queen of Arragon, a Tragi-Comedie,' printed in 1640. 3. 'The History of Edward IV.,' 1640, folio, said to have been partly written by his father. 4. 'Observations upon History,' 1641, 8vo.

HABSBURG, THE HOUSE OF, was the original title of the House of Austria. Rudolf, the founder of the Austrian dynasty, was born in 1218, and was the son of Albert, count of Habsburg in Aargau, and of Hedwige of Kyburg, who was descended through her mother from the once powerful House of Zähringen, and whose possessions he afterwards inherited. Having distinguished himself in the management of his own dominions, he was chosen, after the death of Conrad IV., emperor of Germany by the electoral diet of Frankfort in 1273. The dignity became in reality hereditary in his family, and was enjoyed by his descendants [GERMANY] till the death of Charles VI. in 1740. His daughter, Maria Theresa, having married Francis of Lorraine, grand-duke of Tuscany, an attempt was made to dispossess her of the imperial crown, but it failed, and the succession has been ever since transmitted in the line of Habsburg-Lorraine.

The castle of Habsburg, the manorial residence of Rudolf I., has long since ceased to belong to his posterity. While Rudolf's successors were extending their sway over both hemispheres, they lost by degrees in the wars of Switzerland all their patrimonial domains in that country. Two square towers of the castle of Habsburg still remain, standing on a steep hill on the right bank of the Aar, not far from Brugg, and opposite the baths of Schinznach. The sepulchres of the Habsburg family, which were at Königsfelden, in the neighbourhood, have been removed to St. Stephen's cathedral at Vienna.

HABZELIA, a genus of plants belonging to the natural order Anonaceæ. *H. Ethiopica* is the *Piper Æthiopicum* of the shops. It is a native of Sierra Leone. *H. aromatica* is another species, yielding a pungent aromatic fruit. It grows in the forests of Guyana, and the fruit is used by the negroes as a condiment.

HACHETTE, JEAN NICOLAS PIERRE, was born at Mezières, May 6, 1769. He began his studies at Mezières, where Monge then held a professorship. At the age of twenty-three he was the successful competitor in the *concours* for a professorship of hydrography at Collioure. Some memoirs on mathematical subjects which he addressed to Monge, then minister of marine, procured him to be called to Paris, from whence he was sent to fill a professorship at Mezières, and at the end of 1794 was appointed to the Ecole Polytechnique, at its establishment. In this post he continued till the accession of Louis XVIII., by whose feeble and fanatical

government he had, in 1816, the honour of being deprived of his professorship, at the same time when Monge was expelled from the Institute. The government above mentioned refused to sanction his admission to the Academy of Sciences; nor was it till after the Revolution of 1830 that the fellow-labourer of Monge, the instructor of Poisson, Fresnel, Arago, and of more than two thousand of the best qualified public officers in France, was permitted to sit among his former pupils at the Palais de l'Institut. M. Hachette died in January, 1834, at the time when the cholera was raging in Paris, though not of that disorder.

The greater part of the life of M. Hachette was devoted to the development of the descriptive geometry of Monge, and its application to the arts of life, particularly in the description and construction of machinery. Monge left the details of the descriptive geometry for the most part to Hachette, who made the first special applications, and particularly to the construction of machinery. His works on descriptive geometry (that of Monge being comparatively elementary) and on machinery are in high repute.

HACKERT, PHILIPP, a celebrated landscape painter, was born at Prenzlau, in Prussia, in 1737. His father was a portrait painter and a native of Berlin. Hackert's first works of importance were the six large pictures of the Russian naval victory of Tschesme, and the burning of the Turkish fleet by Count Orlov in 1770, painted for the Empress Catherine II. of Russia, and for which he was paid 2950 zechini, about 16,000 florins, or 1350*l.* sterling. Hackert was highly patronized in Rome both by Italians and foreigners. Pius VI. was delighted with his works. In 1786 the king of Naples appointed Hackert his principal painter. His salary was 100 ducats per month, with his apartments free, both in Naples and at Caserta. Hackert lived, after his departure from Naples in 1799, a short time in Leghorn, whence he removed to Florence, where he resided till his death in April, 1807.

HACKET, JOHN, was born in the year 1592, and educated at Westminster School, whence he was elected to Trinity College, Cambridge, at the age of sixteen. In 1618 he took orders, and became chaplain to the bishop of Lincoln. During the civil war he espoused the cause of Charles, and his house was a kind of rallying point for his party. His zeal, however, led him into difficulties, and he suffered a short imprisonment; but after the Restoration he accepted the bishopric of Lichfield and Coventry, where he died in 1670.

To Bishop Hacket we are chiefly indebted for the restoration of Lichfield Cathedral.

HACKNEY. [MIDDLESEX.]

HACKNEY-COACH. The derivation of the word hackney, as applied to a class of public conveyances, is uncertain. It was applied to horses let for hire, and then, by a very natural transition, extended to coaches employed in a similar way.

Hackney-coaches appear to have originated in London. It was in 1625 that they began to ply in London streets, or rather at the inns, to be called for as they were wanted, and they were at this time only twenty in number. In 1652 the number of hackney-coaches daily plying in the streets was limited by the Government to 200; and an increase was at

different times allowed till 1771, when the number of coaches was further increased to 1000. They were long assailed as public nuisances.

The first hackney-coach *stand* was established in 1634, by one Captain Baily, near the Maypole in the Strand. The monopoly long enjoyed by the London hackney-coachmen produced great indifference to the increasing wants of the community; even down to the year 1823, while that monopoly was undisturbed, hackney-coaches appear to have sunk lower and lower in the scale of efficiency. While this was the state of things in London, a lighter kind of vehicle, called *cabriolets de place*, had been brought into extensive use in Paris. In 1823, licences were obtained for eight cabriolets (or as more commonly called for brevity, cabs), to be started in London at fares one-third lower than those of hackney-coaches. With the rapid extension of this lighter class of vehicles, numerous varieties of construction have been introduced, in which comfortable and safe accommodation, with complete shelter from the weather and separation from the driver, is provided for two, three, or four persons. The name *cab* is still commonly applied to all hackney-carriages drawn by one horse, whether on two or four wheels. During the first few years of the employment of such carriages their number was restricted to 65, but in 1832 all such restrictions were removed.

The hackney-carriages of the metropolis are now regulated as to vehicles, drivers, and fares by the Act 16 & 17 Vict. c. 33 (1853). Every owner of a stage-carriage must take out a licence, which licence the police commissioners are empowered to suspend at any time if the regulations are not strictly observed. The fares for hackney-coaches are fixed at 6*d.* for every mile, or fraction of a mile, or 2*s.* per hour. Each cab is to be provided with a table of fares, and a numbered plate. The driver must not refuse to carry a fare, if the distance be within six miles, or the time within an hour; beyond these limits he may exercise an option. When hired by time, the driver is not bound to go more than four miles an hour, unless paid 6*d.* per mile extra. A reasonable quantity of luggage is to be taken free of charge. If more than two persons ride in a cab, 6*d.* for each is charged (over any distance) beyond the regular fare. All these provisions are enforced by fine or imprisonment.

The licence for every hackney-carriage is now 2*l.* per annum, and the duty 6*s.* or 7*s.* per week, according as the vehicle is worked six or seven days. Drivers are entitled to charge 1*s.* per mile instead of 6*d.* for any portion of their route beyond four miles from Charing Cross, provided the carriage is discharged beyond that limit.

Hackney-carriages, as regulated by law, comprise only those which work within the police limits of the metropolis. Beyond those limits the owners have to pay post-horse duty, and possibly some local tax imposed by the municipal authorities, but none of the duties mentioned in this article. The sum contributed to the national revenue by the London cabs is considerable. The duty of a shilling a day brings in about 80,000*l.* or 85,000*l.* per annum, while the licences raise this to about 4000*l.* more. Of this sum about 13,000*l.* is annually handed over to the Commissioners of Police to defray the expenses of supervision,

watermen, coach-stands, &c. It is computed that seven horses are on an average kept for three cabs. Some of the cab masters own fifty vehicles each; most of them own a few only; and in certain cases the cabman is the owner of the vehicle which he drives. The patent or 'Hansom' cabs, peculiar for their construction and high speed, are generally well-horsed; and there is observable a gradual improvement in the general condition of the horses employed in the London cabs.

HADDINGTON. [HADDINGTONSHIRE.]

HADDINGTONSHIRE is one of the three counties of Scotland included under the general name of the Lothians, and is very commonly called East Lothian. It is bounded S.W. by Edinburghshire, S.E. by the Lammermuir Hills, and N. and E. by the Forth and the German Ocean. It is comprised between 55° 46' and 56° 5' N. lat., and 2° 20' and 3° 2' W. long. The extreme length of the county from E. to W. is about 27 miles, and its extreme width from N. to S. is somewhat less than 16 miles. The area is 179,142 acres, or about 280 square miles. The population, in 1861, was 37,634.

Soil and Surface.—The surface of the county is extremely diversified, though not mountainous. The principal hills are those of the Lammermuir. The general inclination is from the foot of the Lammermuir range towards the N.E., but the descent is far from uniform. From the shore of the Frith of Forth the county consists of a series of parallel ridges running from W. to E., and successively increasing in altitude until they reach the Lammermuir Hills. The soil is very varied in quality in different parts; about four-fifths are under tillage, and the remainder consists of woods, plantations, pastures, and wastes. The climate varies extremely for so small a county, and the period of harvest is a month later in some spots than in others.

The geology of the county presents many points of considerable interest. The tract of country lying between Trapraane Law and North Berwick on one side, and Gallane Point and Whitberry Point on the other, is composed chiefly of porphyries and trap. The Lammermuir Hills, on the south-east of the county, consist, for the most part, of the Silurian rocks of the south of Scotland. Near Dunbar, and stretching to the south-west in the direction of the low slopes of the Lammermuir range, the old red sandstone formation is well developed. The rest of the county consists of rocks belonging to the coal measures, in which coal, ironstone, freestone, and limestone, occur. Patches of stratified rocks crop out on the coast in the neighbourhood of North Berwick. These have generally been set down as the old red sandstone. But the writer of this notice recently (September, 1865) found in them traces of plants characteristic of the coal measures.

The source of the Tyne is in Mid-Lothian, a few miles west of Haddingtonshire; and its mouth is about three miles westward of Dunbar. The river abounds with large trout, eels, and small salmon. The other rivers, or 'waters,' as they are provincially termed, are—the Coalstone, Biel, Whitewater, and Fastna, to the south of the Tyne, and the Peffer to the north, by means of which, and their tributaries, nearly the whole county is well watered. The roads are good, and the North British Railway traverses the county.

Manufactures and Produce.—There are several extensive distilleries in the county, pottery works at Preston-pans and Tranent, and fisheries at Dunbar. It has also manufactures of salt. Coal is worked in the west, and limestone abounds everywhere. The farms are generally large. From Haddingtonshire the improved system of agriculture has been diffused over Scotland, and this county continues to hold a high rank in respect of agriculture and produce. The smaller farms are on the most productive soils. Wheat is the principal grain cultivated, though large crops of beans and oats are likewise raised. The turnip crops are very large. Barley is also extensively cultivated. Since the increase of pasture-land the breeding of sheep and cattle has been extended, but breeding in the lowland and midland districts is carried on upon a very limited scale, the more usual practice being to purchase, chiefly from the Highlands, and fatten for the Edinburgh market. The manure of the farm-yard is that most generally resorted to throughout the county, but seaweed is employed along the coast, and lime in the upper districts. Guano and pulverized bones are also used. Great attention is paid to the drainage of the soil, and the best agricultural implements are used. The first steam-plough used in Scotland was introduced in this county in 1862.

Divisions and Towns.—The county is divided into twenty-four *quoad civilia* parishes, two presbyteries, and three royal burghs. Haddington is the county town. The registered electors in the whole county in 1862 numbered 688. It returns two members: one for the county, and one for the Haddington parliamentary district. The principal towns are the following:—

North Berwick, a royal burgh, is situated on the coast, at the mouth of the Frith of Forth. The town is 22 miles N.E. from Edinburgh. It is contributory to the Haddington parliamentary district. Population of the parish in 1861, 2071; of the borough, 1164. It has a harbour, an active trade in corn, and is much frequented as a bathing-place. The town is the terminus of a branch of the North British Railway. Near it are the remains of Tantallan Castle, one of the prominent scenes in 'Marmion,' and the Bass Rock, which formerly contained a fortress in which many of the leading Covenanters were confined.

Dunbar, a royal burgh, situated 28 miles E. by N. from Edinburgh. The harbour, though difficult of access, is safe and commodious, and will admit vessels of 300 tons burthen. Here once stood the castle to which Queen Mary fled in 1565, after the assassination of Rizzio. The town is now a station on the North British Railway. The population of the parish in 1861, was 4944; of the town, 3796; and of the parliamentary borough, 3516. There is a Gothic parish church, a town-hall, assembly-rooms, public libraries, shipbuilding docks, sail-cloth and cordage factories, iron foundries, breweries, and distilleries. The principal imports are coal and foreign grain; the exports consist of corn, whisky, and fish: there are extensive herring fisheries. The town is of some historical importance, owing to the successful defence of its castle against the English by 'Black Agnes,' countess of March, and to Cromwell's decisive defeat of the Scotch army in the neighbourhood.

Haddington is the county town. It is 18 miles

from Edinburgh, on a branch of the North British Railway. The parish comprises 12,162 acres, which are in the highest state of cultivation; population in 1861, 5548; of the borough, 3897. The town has parish and collegiate churches, a town-house, county buildings, corn exchange, an agricultural and a horticultural society, several public libraries, and a trade in wool. It is, perhaps, the largest market in Scotland for corn and other agricultural produce. Haddington is a very ancient royal burgh, and holds its last charter dated 1624. The town disputes with Gifford the honour of being the birthplace of the celebrated reformer, John Knox. The old abbey, a fine Gothic structure, in partial ruin, is a very interesting object. Haddington, in conjunction with Dunbar, Jedburgh, Lauder, and North Berwick, returns one member to Parliament.

Antiquities.—Circular mounds or encampments are occasionally met with in conspicuous situations. Very recently the proprietor of Seacliff, near North Berwick, discovered on a low skerry, west of Seacliff House, urns of the Roman and Celtic periods, a bone comb, a bone needle, a flint implement, and many bones of oxen, sheep, goats (?), dogs, foxes (?), birds, fishes, &c. With these, one or two fragments of human bones occurred. Some of the bones of the oxen are evidently those of the marsh cow (*Bos longifrons*). The discovery is full of interest to antiquaries. There are also numerous old castles, some of which are in a tolerable state of preservation. Of these it will be sufficient to mention those of Dunbar and Hailes, Tantallan, once the residence of the Douglasses, which stands close to the sea, Dirlton, Luffness, &c.

HADDOCK. [MORRHUA.]

HADES (Gr. *ᾍδης*, 'the grave'), in ancient theology and classical mythology, the nether world, or place of departed spirits, of which various opinions have been formed, and most horrible pictures drawn, according to the imagination or fanaticism of the writers. In Scripture history it is translated *hell*, which, in modern times, is considered as too harsh-sounding for ears polite. In Luke xvi. 23, we have, *Καὶ ἐν τῇ Ἀβύσσῳ τοῦ ἐφθάρμηνος* ('and in hell he lifted up his eyes'). As Calmet observes, 'Jews, Mussulmans, and Christians have all depicted the horrors and the punishment of hell as their several fancies have conceived, and according to various images derived from bodily tortures and pangs.' The term, in all probability, was derived by the Greeks from the ancient Egyptians, who considered Hades as a place of separate abode for the soul preparatory to judgment; whence, in all probability, the Romish doctrine of purgatory, as derived from the Romans, originally sprang.

HADLEY, JOHN, the reputed inventor of the sextant which bears his name, became a fellow of the Royal Society in 1717, and died February 15, 1744. He was author of several useful papers, which appear in the Transactions of the Society, from vol. 32 to vol. 39. He was also upon intimate terms with Sir Isaac Newton, from whom it is supposed he borrowed, without acknowledgment, the idea of the sextant. It is now generally believed that Newton and Godfrey were the original and independent inventors of that instrument. Hadley gave an account of the instrument in the 'Philosophical

Transactions' for 1731; but Newton, previous to his death in 1727, had given a description of the instrument to Dr. Halley, by whom it was, for some unknown reason, suppressed, though it was communicated to the Royal Society in the year 1742, after Halley's death, by his executor, Mr. Jones.

HADRAMAUT. [ARABIA.]

HADRIANUS, ÆLIUS, son of Ælius Hadrianus Afer (a cousin of Trajan, and a native of Hatria Picena, but of Spanish descent), and of Domitia Paulina of Cadiz, was born at Rome, in January, A.D. 76. He was left an orphan at ten years of age, under the guardianship of Trajan, and of Tatianus, a Roman knight. He made great progress in literature, especially in the study of Greek. In the reign of Domitian he served as commander of an auxiliary legion in Mœsia. Trajan gave him his niece Sabina in marriage, and he accompanied the emperor in his Dacian and Eastern campaigns. When Trajan died at Selinus, in Cilicia, in August, 117, Hadrian, whom he had left in charge of the army in Syria, was proclaimed emperor by the soldiers at Antioch, and he wrote to the senate for their confirmation. His election being confirmed by the senate, Hadrian, after making peace with the Parthians and the Armenians, set off for Rome. He refused to appropriate to himself the triumph which had been destined for Trajan, and he caused the image of the deceased emperor to be carried in the triumph. He remitted all the arrears due to the public treasury by individuals in Rome and the rest of Italy, and all that was due from the provinces for sixteen years past; and he burnt in the Forum of Trajan the schedules of the debts, which are said to have amounted to several millions sterling. Medals were struck on this occasion with the figure of Hadrian holding a torch and setting fire to the heap. In 119 he repaired to Mœsia, and drove back across the Danube the Sarmatians and Roxolani, who had invaded the Roman territory. The year after, Hadrian began his travels through the various parts of the empire, which occupied, with few interruptions, the remainder of his reign. We have memorials of his travels in numerous medals, struck in the various provinces on the occasion of his visit. An Italian medallist, Mezzabarba Birago, has put these medals in order and illustrated them. Hadrian first visited Campania, whence he proceeded to Gaul, and the provinces called the Germanies. He affected no pomp or state in his travels. He lived like a soldier among the soldiers. But his liberality for all useful purposes was unbounded.

In 119 he crossed over to Britain, where he reformed many abuses. While in Britain, he constructed a rampart of earth, extending from the Solway Frith to the German Ocean near the mouth of the Tyne, a little to the south of the more substantial wall afterwards raised by Septimius Severus. On his return to Gaul he passed into Spain, and spent some time at Tarraco (Tarragona), where he held a general assembly of the deputies of the various provinces of Spain. Hadrian returned to Rome in 122; but the next year he was at Athens, a city to which he was much attached. He ordered the embankment of the Cephissus, which had damaged the town of Eleusis, and the construction and reparation of various edifices. From thence he went to Syria, where peace was confirmed between the Romans and the Parthians.

In the year following he visited various parts of Asia Minor, and after building temples and other edifices at Nicomedia, Cyzicum, Nicaea, and other towns, he sailed to the islands of the Ægean Sea, and spent the winter at Athens, where he was initiated in the Eleusinian mysteries, and presided at the public games. He next went to Sicily, and ascended the summit of Ætna to see the sun rise. He returned to Rome in 126, and we know nothing of his movements for the two following years. In 129 he set off for Africa, where he distinguished himself, as he had done on his previous travels, by his munificence. Plautina, Trajan's widow, having died meantime, Hadrian returned to Rome, and celebrated her funeral with great ceremony. In the following year (130) he raised a magnificent temple in honour of Venus and Rome, some remains of which are still seen near the arch of Titus. In that year Hadrian set off again for the East. He visited Cappadocia, Syria, Palestine, and Egypt, in which last country he remained two years.

There is a letter of Hadrian, written from Alexandria, to Servianus, his brother-in-law, in which he describes the state of the population of Egypt and speaks of the various sects, Jews, Christians, Samaritans, who were very numerous in that country. He says that they all adored but one god, their own interest. He restored the palace and museum of Alexandria. About this time his favourite Antinous died; some say he drowned himself in the Nile, and Hadrian disgraced himself by the apotheosis and other absurd honours which he paid to his memory. He next went to Cyrenaica. In 133 Hadrian repaired to Syria, from whence he set off for Thrace and Macedonia, and lastly stopped at Athens. The insurrection of the Jews of Palestine under Barcochebas raged about this time, and the Romans had to carry on against the Jews a war for three years. [BARCOCHEBAS.] Hadrian raised a new city on the ruins of Jerusalem, which he called Ælia Capitolina, and he peopled it with a Roman colony. Jews and Christians were forbidden to enter the new city. Hadrian meantime made another long residence at Athens, and he greatly embellished that city, a district of which was called by the name of Hadrianopolis. He also completed the temple of Jupiter Olympius. He returned to Rome in 135. Soon after, falling ill, he thought of choosing a successor, and he fixed his choice upon Ceionius Commodus Verus, whom he adopted and appointed Cæsar by the name of Ælius Verus. In the following year Hadrian retired to the neighbourhood of Tibur, where he built a magnificent villa, many remains of which still exist. Protracted illness seems to have soured his naturally suspicious temper, and he condemned several individuals to death, among others his brother-in-law Servianus. Ælius Verus having died in the second year after his appointment as Cæsar, Hadrian fixed his choice upon Titus Aurelius Antoninus, on condition that he should adopt Lucius Verus, son of Ælius Verus. Antoninus accepted the proposal, and the double adoption was solemnized in February, 137. Sabina, Hadrian's wife, died about this time, and was numbered among the gods. Hadrian still finding his illness increasing, at last removed to Baia. He died in July, 138, in his sixty-third year, and the twenty-first of his

reign. (Spartianus, 'Life of Hadrian,' Dion; Aurelius Victor; Eusebius.) Hadrian was a man of great abilities and large acquirements, an encourager of sculpture and architecture, a good administrator, and very attentive to business. But he was not free from vices, if we may trust the evidence of the historians. It is said that he was the first emperor who allowed his beard to grow, in order to conceal some blemish on his face. Under Hadrian the distinguished jurist Salvius Julianus compiled the 'Edictum Perpetuum.'

The busts, statues, and medals of Hadrian are very numerous, and all bear a striking resemblance to each other in the character of the countenance. There is a full-length statue of him and two busts in the Townley Gallery, British Museum.

Coins of Hadrianus. British Museum.
Actual Size. Copper.

Reverse.

HÆMATITE (sometimes written *Hematite*), the name of one of the iron ores. Two species are distinguished. The one, *Red Hæmatite*, which yields peroxide of iron 94.0, silica 2.0, lime 1.0, and water 3.0; the other, *Brown Hæmatite*, affords peroxide of iron 84.0, water 11.0, oxide of manganese 2.0, and silica 2.0. It is thus a hydrous peroxide of iron; the proportion of peroxide of iron and water being as 85.30 to 14.70.

HÆMATOCOCCUS, a genus of plants belonging to the natural order of *Algæ*. Several species of this genus have been described. One of the first observed was the *H. sanguineus*, which, like the Red-snow Plant (*Protococcus nivalis*), has its cells coloured red; hence the generic name. Several of the species, however, are of a green colour. They are found upon most rocks, on the walls of caverns, and in damp places. Mr. Hassall has described several new species of this genus; they belong, however, to a class of plants in which it is most difficult to discover permanent specific characters.

HÆMATOPS, a name given by Mr. Gould to a genus of birds inhabiting Van Diemen's Land and New South Wales.

Mr. Gould recorded two species, *Hæmatops valdirostris*, $6\frac{3}{4}$ inches in length (Van Diemen's Land), and *H. gularis*, 6 inches long (New South Wales).

HÆMATOXYLON CAMPECHIANUM (*Logwood*), a tree native of Campeachy, but cultivated also in Jamaica. The finest wood is the produce of the former place. The bark and alburnum being removed, there is within a dark red coarse-fibred duramen, having a violet-like odour, and a taste at first sweetish, afterwards astringent. It dyes the saliva violet-colour, and produces a similar change on many of the other secretions.

Logwood acts as a mild astringent in hæmorrhages or increased secretions; and in some forms of diarrhœa it often effects a cure where more powerful astringents fail. It may be exhibited in the form of infusion or of extract: the former is preferable. Logwood is also used extensively in the arts, especially for dyeing.

The imports of logwood into the United Kingdom in 1863 amounted to 38,404 tons, valued at 213,181*l*. The principal supplies came from the West Indies, United States, Honduras, Hayti, and St. Domingo.

HÆMODORA/CEÆ. Under this name Dr. Robert Brown proposed, in the year 1810, to separate several genera from the natural order *Iridacæ*. The order may be considered a connecting link between *Iridacæ* and *Liliacæ*. The rhizoma species, *Dilatris heritieri*, yields a dyeing matter.

HÆMOPITYSIS (from *αἷμα*, 'blood,' and *πίσις*, 'to spit'), a spitting or coughing of blood.

HÆMORRHAGE (from *αἷμα*, 'blood,' and *ρῥυσις*, 'to break'). The most common cause of hæmorrhage is external violence, by which the vessels of a part are divided, and the blood escapes from their cavities. When an artery is wounded, a bright scarlet stream of blood is emitted in a current, continuous, but increased in force at intervals corresponding with the pulsations of the heart. If a vein of some size be divided, a stream of dark crimson blood is projected in a perfectly continuous and equable current. In wounds in which no vessel of more than a line in diameter has been divided, the blood flows in a constant more or less rapid oozing.

When a large artery, as one of the main trunks of the limbs or head, is divided, the blood rushes forth with such impetuosity, that life is often destroyed almost instantaneously.

When an arterial branch of the second magnitude, as one of the primary divisions of the main trunks in the leg or fore-arm, is wounded, the flow of blood is at first profuse, and a large quantity is soon lost; but after a time the patient faints from extreme exhaustion, and then, the heart ceasing to act, the blood no longer flows, but begins to coagulate both within and around the vessel, whose extremities contract, and further loss may thus be prevented. More frequently, however, as soon as the patient recovers from his exhaustion, and the heart regains some of its power, the slight obstacles formed during the fainting are forced away, and the hæmorrhage recommences, and continues till the patient is again exhausted. Thus, by a suc-

cession of hæmorrhages and of temporary stanchings, he may at last be destroyed by extreme debility. From arteries of smaller size, as those about the fingers, &c., the blood flows at first in a rapid little stream; but after a few minutes, if they are exposed to the cold air, they retract, their orifices contract and close, and the bleeding altogether ceases, without much danger of returning.

Hæmorrhage from wounded veins is of less importance. It is much more slow, for the blood is prevented by the valves from flowing from that part of the vein which is between the heart and the orifice, and in the part which is beyond the orifice it has only the force of that in the smaller arteries. Hence it is seldom immediately fatal; but when the patient becomes faint the edges of the vessel fall together, instead of remaining open, as those of arteries. Thus a coagulum forms within and round them, and, except from the largest trunks, prevents any further flow.

But bleeding to a great extent may take place without visible rupture of any vessel. This form of hæmorrhage, which may take place in various parts of the body, is that popularly supposed to arise from the 'bursting of a blood-vessel;' but in the large majority of cases, where blood is poured forth in the interior of the body, the most careful examination can discover no aperture through which it had flowed. It is therefore called hæmorrhage by exhalation, from the idea that the vessels, which in health are traversed only by the fluids of the exhalations or secretions, now permit the passage of the blood.

The circumstances under which these hæmorrhages take place are various. In some cases they arise from distension of the vessels in consequence of some local excitement, either with or without increased activity of the circulation generally; and in these the flow of blood is preceded by a sensation of fulness and throbbing in the part, which, if visible, appears red and swollen. Such are those which take place in bronchitis, producing some rare cases of hæmoptysis; in dysentery and acute inflammation of the intestines; from the membrane of the nose, producing the epistaxis so common in young persons in robust health; in the brain, producing some forms of apoplexy, especially those connected with hypertrophy of the heart; and occasionally in the acute inflammations of nearly all the tissues. In other cases the main cause of the hæmorrhage is the existence of some obstacle to the free passage of the blood through the vessels. Such are those very frequent cases in which hæmoptysis, or spitting of blood, takes place in consumption, where the blood is obstructed in its passage through the pulmonary arteries by the masses of tuberculous matter deposited around them; those of hæmatemesis, or vomiting of blood, which arise from obstruction of the splenic or portal vein, by coagula, or by disease of the liver or other adjacent organs, and the consequent congestion of the vessels of the stomach; many of those which occur from the stomach, uterus, and other organs, in the early stages of various structural diseases; those which depend on disease of the heart, producing obstruction in the large vessels, and which may take place in the brain, lungs, and various other organs; and those arising from obstacles in the veins, as in hanging, or even from the influence of gravitation.

But a simply mechanical distension of the vessels, whether from an increased afflux of blood into them, or a retarded removal of it from them, cannot explain all the phenomena of these spontaneous hæmorrhages. In some persons there exists a peculiar tendency to bleeding in the vessels, and this is called the hæmorrhagic diathesis. In other cases the blood appears to be in fault, as in scurvy, purpura, and the low forms of typhus.

Of the means of arresting Hæmorrhages.—When an artery is wounded, unless death rapidly follow, a natural process takes place by which further bleeding may be prevented. If completely divided, both extremities retract into the sheath of cellular tissue in which they lie, so that a considerable interval is produced between them, bounded by loose and irregular walls, into which the blood as it flows infiltrates, and, coagulating, tends to fill it up and obstruct the vessel. The open mouths of the artery also contract, and gradually but at last completely close, either at or just above their extremities. As the stream is thus checked by the narrowing and closure of its canal, at the same time that by the faintness induced by the previous loss the action of the heart is weakened and the whole circulation retarded, it begins to coagulate within the vessel itself, till its tube is nearly filled by a clot adhering loosely to its walls. Further changes then ensue; the divided vessel and the parts around become inflamed; coagulating lymph is effused from the edges of the wound into the artery itself and over its extremities, forming a firmer plug than the blood alone had; in process of time this lymph becomes organized, vessels enter it from the parts around, and it becomes firmly and permanently united to them and the vessel, till at length its tube is rendered impervious from the point of division up to the first branch given off from it, and is at last converted into a solid cord, closely connected with the substance of the cicatrix around it.

But it is only in the very small arteries that the hæmorrhage can be confidently expected to terminate thus naturally, and hence various artificial means of checking bleeding from the larger ones have been invented. The simplest of these is pressure; if the finger be placed with moderate firmness over the mouth of a small bleeding vessel for a minute or two, on removing it the orifice will be found closed and no more blood will flow. Bandages and the tourniquet may be applied for the same purpose. But, if these means be insufficient, the artery must be tied; if it be completely divided, ligatures must be placed on both extremities; and, if only partially cut, then on both sides of the opening, for, from the numerous communications of the arteries, when the main current is checked, another in a retrograde direction is always established into the part beyond the ligature. Sometimes astringent applications, as alum or sulphate of copper, will arrest slight bleeding. Spongy substances, as lint, agaric, &c., act mechanically in arresting hæmorrhage.

Such are the principal modes of treatment applicable in cases of external or surgical hæmorrhage, in which vessels are divided by external injury, and are within the reach of the eye or fingers. In internal hæmorrhages, however, it is obvious that mechanical means can rarely be employed. From

the varied nature of the cases from which they arise, it is evident that different means will be required, according to the several conditions of the system. If astringent remedies be deemed advisable, and in many cases they are highly useful, the acetate of lead will generally be preferable, and next to it the different vegetable compounds of gallic acid.

HÆMORRHOIDS (from *αἷμα*, 'blood,' and *ρῆμα*, 'to flow'), varicose tumours of the veins of the rectum. [VEINS, DISEASES OF.]

HÆMULON, a genus of fishes of the section *Acanthopterygii* and family *Sciænidae*. Generic characters—a single dorsal fin; seven branchiostegous rays; lower jaw compressed, a small oval opening and two small pores under its symphysis; the vertical fins partially covered with scales.

These fishes generally approach to an elongate oval form; the body is moderately compressed; the tail is forked; the dorsal fin, which occupies the greater portion of the distance between the back of the head and the tail, although continuous, has a considerable indentation at that part where the spinous rays join the flexible. The portion of the under jaw which is covered by the upper when the mouth is closed is invariably of a bright red colour. The species of *Hæmulon* chiefly inhabit the Caribbean Sea, and are eaten by the inhabitants of the West Indian islands. They are of moderate size, varying from six inches to one foot in length, and generally adorned with longitudinal or oblique dark markings on a pale ground colour.

HÆMUS. [BALKAN.]

HAFIZ, MOHAMMED SHEMS EDDIN, a celebrated Persian poet, was born at Shiras, at the beginning of the fourteenth century of the Christian era. He appears to have remained in his native town the greater part of his life. The date of his death is uncertain; it is placed by Daulet Shâh in 1389. A splendid monument was erected over his grave, which is described by Kaempfer; and Franklin gives us an account of another monument erected to his memory in more modern times.

The poems of Hâfiz, like those of Anacreon, celebrate the pleasures of love and wine. They have always been greatly admired in Persia, though many Mohammedans have condemned them for their irreligious and licentious tendency. The admirers of Hâfiz, on the other hand, contend that his poems are not to be understood in a literal, but in a figurative or allegorical sense; and that they express in emblematical language the love of the creature to the Creator. The sect of the Sûfis, who interpret the poems of Hâfiz in this manner, possess many similar poems.

The poems of Hâfiz were arranged, after his death, by Saïd Kâsem Anvârî, and were entitled the 'Divân.' The 'Divân' contains, according to the best MSS., 571 odes, called ghazels. They were published in the original Persian, at Calcutta, 1 vol. folio, 1791; this edition contains only 557 ghazels, and seven cassidehs, or elegies. The whole 'Divân' was translated into German by Von Hammer, Tübingen, 1812; and several of the odes have been translated into English by Richardson, 'Specimen of Persian Poetry, or the Odes of Hâfiz, with an English translation and paraphrase, chiefly from the Specimen Poeseos Asiaticæ of Baron Rewuski,' London, 1774; Nott,

'Select Odes of Hâfiz translated into English verse,' 4to. London, 1787; Hindley, 'Persian Lyrics, or scattered poems from the Diwah-i-Hâfiz,' 4to. London, 1800.

HAGGAI, one of the twelve minor Hebrew prophets. We know nothing concerning the place or time of his birth. The date of his prophecy is fixed by himself (i. 1) in the second year of the reign of Darius, son of Hystaspes (B.C. 519). The canonical authority of the book has never been denied. It is quoted by the author of the Epistle to the Hebrews, xii. 26. Compare Haggai ii. 7, 8, 22.

HAGUE, THE (in Dutch, 's *Gravenhage*; in French, *La-Haye*), a large and beautiful city, the capital of the Dutch province of South Holland, stands in 52° 4' 50" N. lat., 4° 18' 32" E. long., at a distance of two miles from the North Sea, 37 S.W. from Amsterdam, and 13 N.W. from Rotterdam by the railroad which connects those cities. It is not fortified, but is surrounded with a moat crossed by drawbridges. It is ranked as one of the finest cities in Europe on account of its stately buildings, its broad and regular streets traversed by canals, and its pleasant, dry, and healthy situation. Many of the streets are planted with rows of trees and paved with coloured bricks. The finest parts of the town are the Voorhout, which is lined with trees, and contains several splendid hotels, and the Vyverberg, a sort of square, with a fine avenue of trees on one side, and on the other a spacious basin of water, backed by magnificent buildings. Among the public buildings are—the royal palace, a building of little pretension; the former residence of the stadtholder, in which the States-general now hold their sittings; the palace of the prince of Orange; the Buitenhof, which contains a gallery of pictures; the town-hall; the brass-cannon foundry; the theatres; and the state-prison. The Binnenhof, on one side of the Vyverberg, contains a magnificent Gothic hall, the only remaining portion of the original residence of the counts of Holland. The Maurits-huis contains the finest collection of paintings by Dutch masters in the world, a vast collection of Chinese and Japanese products and curiosities, besides numerous historical relics. The Royal Library in the Voorhout contains 100,000 volumes, and a collection of 34,000 medals. De Witt's house in the Kneuterdyk, and the Gevangpoort (prison-gate), from which Cornelius and John De Witt were dragged by the populace and torn to pieces in 1752, are historically interesting. There are fourteen churches—the most notable being that of St. James, with its lofty hexagonal tower, and peal of thirty-eight bells—two Jews' synagogues, several Protestant chapels, numerous charitable and scientific institutions, and fine private collections of pictures. There are a royal country seat and numerous elegant villas in the environs.

The Hague owes its origin to a hunting-seat built by the counts of Holland in 1250, and the Dutch name, 's Gravenhage, is said to be taken from the circumstance that houses came to be erected along the inclosure surrounding the Counts' Park ('s Gravenhage, 'counts' hedge'). In the sixteenth century the Hague became the residence of the States-general, the stadtholder, and the foreign ambassadors. The Hague ranked only as a village till Louis Bonaparte,

during his reign, conferred on it the privileges of a city. The population in 1862 was 82,620.

Canon casting, printing, and various manufactures are carried on, but the Hague is not important as a commercial or manufacturing city—depending for its prosperity almost entirely on the court and nobility. William III. of England, and Huyghens the mathematician, were born at the Hague. In the immediate neighbourhood of the Hague are Ryswick, celebrated for the treaty of peace signed there in 1697, and Schevingen, a famous bathing place on the sea-coast, two miles from the town, with which it is connected by a broad causeway, planted with rows of trees.

HAGUE, LA, CAPE. [MANCHE.]

HAGUENEAU. [RHIN, BAS.]

HAHNEMANN, SAMUEL, founder of the system of medicine called Homœopathy, was born at Meissen, in Upper Saxony, on the 10th April, 1755. His father, Gottfried Hahnemann, who was an artist of considerable merit, was employed in the painting of china in the celebrated porcelain manufactory of Meissen. He was placed at an elementary school, the director of which, Dr. Müller, remarking talents that only required cultivation to raise the boy to eminence, persuaded his father to place him at the High School of Meissen, into which they obtained him a free admission. Hahnemann gladly availed himself of these increased facilities; he made himself master of Latin, Greek, and Hebrew, and evinced a decided bias for the study of the physical sciences, natural history, and medicine. Botany was also a favourite pursuit, and his hours of leisure were devoted to the collection of plants and their systematic arrangement.

Having chosen medicine for his profession, at the commencement of 1775 he left the High School of Meissen, and he entered the University of Leipzig.

He supported himself during his residence at Leipzig by giving lessons in German to foreign students, and by the translation of English and French medical authors. Having passed two years in the study of the theory of medicine, and saved a small sum of money, he departed for Vienna, there being no clinical lecturer in the University of Leipzig, and entered himself at the Hospital of Charitable Brothers, with a view to the completion of his studies, and to acquiring a practical knowledge of his profession.

His moderate pecuniary resources were almost exhausted, when his talents and marked attention to his duties gained for him a firm friend in Dr. Quarin, physician to the emperor of Austria, and chief physician to the hospital, through whose recommendation, although he had not yet graduated, Hahnemann obtained the situation of family medical attendant and librarian to Baron von Brückenthal, governor of Siebenbürgen, then residing at Hermannstadt. He remained here for two years, and being allowed to attend private practice he saved a small sum of money; with this he removed to Erlangen, where, on the 10th of August, 1779, he took his degree of M.D. In 1781 he was appointed district physician at Gomers, near Magdeburg, where he married.

In the year 1784 he removed to Dresden, where he gained a high reputation in the hospitals as a judicious and skilful practitioner; but, struck with the absence of a guiding principle in therapeutics, and

the great uncertainty of the healing art, he gradually withdrew himself as much as possible from practice, and endeavoured to support his family by his old resource of translations of English and French medical authors, pursuing at the same time his favourite study of chemistry.

In the year 1790, while engaged upon the translation of the 'Materia Medica' of Cullen, he was struck with the different explanations given of the mode of operation of Peruvian bark in intermittent fever: and, dissatisfied with them, he determined to try its effects upon himself. Finding that powerful doses of this substance produced symptoms strikingly analogous to those of that form of intermittent fever, for which it was an acknowledged specific, he determined to try further experiments with other medicinal substances upon himself and upon some medical friends. He obtained similar results; that is, he produced by these agents factitious or medicinal disorders resembling the diseases of which they were esteemed curative; and thus the first dawn of the law of *Similia similibus* gleamed upon him.

In 1801 he published a short treatise on the efficacy of belladonna in the prevention and cure of scarlet fever, and affirmed that its curative properties were based upon the homœopathic law. In 1810 he brought out his great work, 'The Organon of the Healing Art,' in which he developed his new system of treating disease, and for the first time gave it the name of 'Homœopathy,' by which it has since been distinguished.

In the year 1812 he returned to Leipzig, where he was appointed Magister Legens. At Leipzig he had an extensive practice, and was assisted by a great number of friends and pupils in the proving of his medicines. The apothecaries of that city, however, rose against him, and appealing to an old law long dormant, that forbade a physician to dispense his own prescriptions, they eventually, after some litigation, succeeded in 1820 in obtaining a decision in their favour. Hahnemann, unwilling to risk his own reputation and that of his system upon medicines prepared and dispensed by individuals avowedly hostile to his medical tenets, had determined to retire from practice, when the duke of Anhalt Cöthen offered him an asylum in his dominions, with the enjoyment of those privileges of which he had been deprived at Leipzig.

Having been a widower for some years, he married in 1835 a French lady, who had visited Cöthen for the benefit of his advice, and with her removed to Paris. He remained there in the exercise of his profession, and surrounded by numerous followers of his system, of all nations, till the time of his decease, which took place on the 2nd July, 1843, in the eighty-ninth year of his age. On the centenary of his birth, in 1855, a statue was erected to his honour in Leipzig, at the expense of his disciples in England, France, Germany, and other countries, with the concurrence of the local authorities, who supplied the site in one of the best places in the town.

HAIL. [SNOW.]

HAILES, LORD. [DALRYMPLE, SIR DAVID.]

HAINAN, an island in the Chinese Sea, opposite the southern extremity of the province of Quan-tung, or Canton, from which it is divided by the Channel of the Junks, a strait only fifteen or sixteen miles

wide. It lies between $18^{\circ} 10'$ and $20^{\circ} 24'$ N. lat., and $108^{\circ} 25'$ and 111° E. long., and incloses the Gulf of Tonquin on the east. Its length from south-west to north-east may be about 200 miles, and its average breadth perhaps not less than 100 miles; its surface is estimated to cover an area of 12,000 square miles.

The interior of the island is occupied by an extensive mountain-mass, some parts of which rise above the snow-line), called Ta Utshi Shan, or the Great Utshi range: from this there issue a great number of offsets, which are separated from the south-eastern and north-western shore by a level tract of considerable width. The extensive forests which cover the sides of the mountains form the principal wealth of the island. The climate is not very hot, being exposed to the wind which blows over a large expanse of sea. Fogs and heavy dews are frequent, and maintain a vigorous vegetation.

The population probably comprises 1,000,000 Chinese, exclusive of aboriginal wild tribes in the interior, who are so far independent that, in 1831, they repulsed a strong Chinese force brought against them by the governor of Quan-tung in person.

In the south are several good harbours. Exports—rice, sugar, wax, pearls, coral, salt, gold, silver, and timber. There are large rivers, but the soil is not fertile, timber being the principal product. The island is divided into thirteen districts. *Kiong-tchou*, the capital, is a populous city, on the northern coast, containing, it is estimated, 100,000 inhabitants. It is inclosed by strong walls, has two colleges, a public library, and a trade with Macao, Assam, Siam, and Singapore. Its port, *Kiung-chow*, is one of those opened by the treaty of Tientsin. Near the island whaling is pursued with great success by Chinese fishermen.

HAINAULT (*Hene-gouwen*), a province of Belgium, bounded N. by East Flanders and South Brabant, E. by Namur, S. by France, and W. by West Flanders, lies between $49^{\circ} 58'$ and $50^{\circ} 48'$ N. lat., $3^{\circ} 17'$ and $4^{\circ} 33'$ E. long.; its greatest length is 63 miles, and its breadth 32 miles. The area is 1441 square miles, and the population in 1861 was 825,216. This province is extremely rich in coal, and contains the three principal mines of the kingdom.

The surface is for the most part level, but there are some hills towards the south and east. The soil, except in the arrondissement of Charleroi, in the south-east of the province, is very fertile. The chief crops are wheat, rye, oats, barley, beans, rape, flax, hops, and potatoes; tobacco and chicory are also grown. Much of the land near the rivers is laid out in meadow; in other parts trefoil, lucerne, and sainfoin are cultivated. Horned cattle, horses, and sheep of excellent breed are numerous; poultry, game, and bees abound. The *Schelde* enters the province from France a little below its confluence with the Scarpe, and flows N.W. to Tournay; then changing its course to north, it forms the boundary-line between Hainault and West Flanders, and quits the province at its north-western angle. The *Sambre* enters the province also from France, to the E. of Maubeuge, and flows N.E. past Charleroi to join the Meuse at Namur. The *Dender* rises within the province, flows eastwards to Ath, whence it turns almost due north, quitting Hainault at Grammont, and, having

crossed a great part of East Flanders, enters the Schelde at Termonde. The *Haine*, from which the name of the province is taken, is formed by three brooks, which rise a little to the west of Charleroi; it flows W. past Mons, below which it is navigable by means of sluices, and joins the Schelde at Condé in France. The *Trouille* rises on the southern frontier, and flowing W. enters France, but leaves it again almost immediately, and falls into the Haine near Jemappes.

The province is traversed by several good roads and numerous canals, by which communication was much facilitated, even before the making of railways; but like every other part of Belgium, it is now well supplied with this rapid means of transit.

The commerce of the province is composed of its varied industrial pursuits—glass, porcelain, pottery, salt, spirits distilled from grain, beer, machinery, woollen stuffs, linen, lace, Brussels carpets (the great manufacture of which is in Tournay), &c. The most considerable articles of export are coal, iron, and lime, which are transported by canals and railroads to France and the neighbouring countries. Slates, marble, and building stone are quarried.

The province is divided into three arrondissements, Mons, Tournay, and Charleroi. The principal towns are the following:—*ATH*. *Beaumont*, on the road from Mons to Chimay, stands on a hill commanding an extensive view over a very diversified country, the surface of which is broken by steep hills, and limestone and schistose rocks. It was formerly fortified, but its defences were demolished by the English in 1691; population, 2091. *Binch*, W. of Charleroi, on the right bank of the Haine, is a well-built walled town, with 5235 inhabitants. In a fine square, ornamented with a fountain, stand a church, a college, and an hospital. The principal articles of manufacture are cutlery and hardwares, lace, paper, marble, and coal. *Braine-le-Comte*, at the junction of the Brussels-Valenciennes railroads, has cotton-mills, breweries, dyehouses, tannards, oil-mills, and 6221 inhabitants. *Charleroi*, a strong fortress on the Sambre, 23 miles E. from Mons, stands on the Brussels-Namur Railway, and has 12,782 inhabitants. It is also a manufacturing town; glass, salt, sugar, leather, nails, woollen yarn, &c., are among its products. The town stands in a most extensive coal-field, which gives employment to upwards of 10,000 men, and yields annually 3,000,000 tons of coal. The number of smelting furnaces, iron foundries, and nail factories in the surrounding district is very great. *Châtelet* is a small town, 4 miles E. from Charleroi, with 4000 inhabitants, who manufacture cotton, woollens, pottery, salt, beer, and leather. *Chievres*, a small town with 3107 inhabitants, near Ath, has important linen manufactures, potteries, breweries, and oil-mills. *Chimay* stands 24 miles S. from Charleroi, near the French frontier; it contains a college, and 3041 inhabitants, many of whom are engaged in the numerous iron-works and coal-mines of the vicinity. There is a castle and park at Chimay, and several breweries. *Enghien*, 12 miles N.E. from Ath, contains 3742 inhabitants. The town is built on the side of a hill; it is regularly laid out, and well built; it contains a college and an hospital. The château of the duc d'Arenberg, which was surrounded by a beautiful

park, was destroyed at the first French revolution. The park still remains; it contains a temple, to which seven noble avenues of beech and chestnut converge. *Fontaine l'Evêque*, 6 miles E. from Charleroi, contains 3018 inhabitants. It has several smelting furnaces, iron foundries, and nail factories. *Gosselies* stands 5 miles N. from Charleroi. The population, including commune, is 4686, engaged in manufactures of woollen cloth, hats, nails, and cutlery. Near Gosselies is *Gilly*, which has a population of 5618. *Lessines*, a town with 4971 inhabitants, north of Ath, is almost surrounded by the Dender. This is a place of much trade. The neighbouring quarries furnish large quantities of paving and building stone. There are salt refineries, distilleries, and chicory factories. The other chief branches of traffic are coal, wood, and oil. *Leuze*, 10 miles E. from Tournay, stands near the source of the Dender, and has 5880 inhabitants, many of whom are employed in manufactures. *Mons. Péruwelz*, 12 miles E. by S. from Tournay, on a feeder of the Schelde, is a town of 7879 inhabitants, who are principally occupied in breweries, lime-burning works, and some linen factories. *Rœulx*, a small town containing 2701 inhabitants, is situated 8 miles N.E. from Mons. The castle of Rœulx, surrounded by gardens and grounds in the English style, is much admired. *St.-Ghislain*, 7 miles W. from Mons, in the middle of a great coal district, stands on the Haine, and has 1956 inhabitants, who are engaged in bleaching linen, tanning, salt-refining, soap-boiling, and brewing. *Soignies*, a well-built town on the Senne, is 9 miles N. from Mons, on the Brussels-Valenciennes Railroad, and contains 6776 inhabitants. Many of the houses are large and handsome. The town is surrounded by old ramparts. The church of St. Vincent is said to be the oldest building in the province. There is a college in the town, an orphan asylum, a convent of the Sisters of Mercy, and several other religious and charitable establishments. Beer, spirits, and leather are manufactured; and the large limestone quarries here are a source of considerable profit. *Thuin*, on the Sambre, 7 miles S. from Charleroi, stands partly on a steep rock, and contains 3989 inhabitants, many of whom are engaged in the iron mines and great iron works in the vicinity. There are also manufactures of woollens and linens. *TOURNAY. Courcelles*, 5 miles N.W. from Charleroi, contains 3226 inhabitants, who manufacture nails and table-linen. *Dour*, 8 miles S.W. from Mons, has a custom-house, and a population of 5833 inhabitants, many of whom find employment in the productive coal-mines of the district. *Fontenoy*, an inconsiderable village, 4 miles S.E. of Tournay, is historically famous for the great battle fought there, May 11, 1745, between the French under Marshal Saxe, and the allied English, Austrians, and Dutch, commanded by the duke of Cumberland, who was defeated with the loss of 15,000 men. *Hornu*, a village of 3050 inhabitants, 5 miles W. from Mons, is the seat of considerable coal-mines. The village is built on a regular plan, and inhabited almost entirely by the miners and iron-forgers of the neighbourhood. Steam engines are manufactured here. *Jemappes*, the first station S. of Mons, on the Brussels-Valenciennes Railway, has a population of 4670. It is celebrated for the

victory gained on the 6th of November, 1792, over the Austrians, by the French under Dumouriez and the duc de Chartres (the late king, Louis Philippe), and which led to the conquest of Belgium. *Jumetz*, 3 miles N. from Charleroi, contains 6528 inhabitants, who are engaged in the coal-mines and in manufacturing glass, beer, and spirits.

HAINAULT, FRENCH, a district in the north-east of France, which formed with the Belgian province of Hainault the territory occupied by the ancient Nervii, whose capital was Bagacum, now Bavay. It was ceded by Spain to France by the treaties of the Pyrenees (November 7, 1659) and Nimeguen (September 17, 1678). Valenciennes, Maubeuge, Condé, Bouchain, Avesnes, Le-Quesnoy, and Landrecies were the principal towns of this district, which is now included in the department of NORD.

HAINES, river. [ZANGUEBAR.]

HAIR. The hairy coverings of mammalia are composed of long delicate processes of a horny substance, which grow from bulbs situated in or beneath the skin. Each hair is contained at its lower part in a delicate sheath, or follicle, which passes obliquely from the surface of the skin on which it opens to a greater or less depth, and at its base dilates into a pouch containing the bulb of the hair. The bulb of the hair consists of a small cone-shaped body, the pulp, soft and delicate, and apparently made up of bloodvessels and nerves, and covered by a reflection of the smooth lining of the sheath of the hair, which is continued from the cuticle covering the surrounding skin. On the whole surface of this bulb the substance of the hair is secreted, and as each layer which is deposited pushes that previously formed onwards, the whole gradually advances along the

Fig. 1.

sheath till it projects beyond the skin, and thence continues to grow free. Into each hair-follicle, as Gurlt has shown, there open the ducts of one or two little glands, by which the oily matter is secreted to lubricate the hair and keep it supple and firm, and where these are deficient the same purpose seems to be performed by the follicle itself. Fig. 1 represents an oblique section of the pulp and lower part of the

whisker of a lion, in the Hunterian Museum, in which *a* is the body of the hair, *b* the conical pulp, and *c* a bloodvessel passing into and ramifying in it. Fig. 2 is a section of the skin, containing a hair

Fig. 2.

from the human scalp: here *a* is the thin cuticle, *b* the cutis, *c* the subjacent fat, *d* the cellular tissue, in which the base of the hair follicle, *e*, is seen; *f* is the hair itself, enlarged at its base, and *g g* are the two sebaceous glands opening into the sheath.

In man the hairs are not, as has been generally supposed, perfectly cylindrical. Weber has shown that they are all more or less flattened, so that a transverse section presents an elliptical form, or sometimes, from one side being grooved, has the shape of a bean. The hair of the whiskers, beard, and moustaches, and in general all short curly hair, is most flattened. In most instances flatness and curliness are directly proportionate, and both attain their maximum in the crisp woolly hairs of the negro, which are sometimes as much as two-thirds broader in one direction than in the other. The hair of the negro, however, though called woolly, differs considerably from the wool, properly so named, of sheep and other animals: the latter is not spirally curled, but wavy, all its curves being nearly in the same place; it is much more delicate, and perfectly round, and hence, from its being equally fitted to curl in any direction, is peculiarly adapted for spinning, while the flattened hairs of men have always a tendency to turn their broadest surfaces towards the middle of the curl.

Except at their base, into which the conical pulp enters to a variable distance, the hairs are perfectly solid, and in most animals their substance is similar throughout. The average diameters of hairs from the human head are respectively about 1-300th and 1-500th of an inch, and hairs often attain a length of six or seven feet in women. Instances are recorded also of the hair of the beard growing to a length of nine feet.

Hairs are very elastic; they admit of being stretched nearly one-third of their length, and regain their original length almost completely: in proportion to their size they are very tough and firm. In masses they are impenetrable, except to very great violence, and hence one of their uses in the thick coverings of animals; they are also adopted in armour, as for the coverings of helmets. Hairs are bad conductors of both heat and electricity, and their oiliness prevents the influence of moisture on the animal body.

In chemical properties hair resembles horn, nails, &c. It is soluble in water at a very high temperature, as in a Papin's digester, leaving a large quantity of oil mixed with sulphuret of iron, and some sulphuretted hydrogen. It is this oil, with the sulphuret of iron, which gives the colour to the hair, and by whose absorption grayness is produced. The iron is most abundant in the darkest hair, and the sulphur is the ingredient on which the action of the various black dyes for red or gray hair depends.

HAIR DYEING. This practice is very ancient, and has been resorted to by savages as well as by the more civilized nations. It is generally done to darken the hair, or to hide the approach of gray hairs. Vegetable dyes were formerly used, but those now sold for the purpose are chemical solutions, either oxides of silver, mercury, lead, or bismuth, and notwithstanding their general use are very injurious.

HAIR MANUFACTURES. There is a considerable amount of industry bestowed upon human hair and the hair of certain animals, in the production of manufactured articles. These consist of fabrics woven or felted of various kinds of hair, brushes, and ornamental hair-work. The latter are chiefly wigs, false curls, numerous contrivances for supplying a deficiency of hair, or giving an appearance of greater abundance to the natural supply, chains, guards, and hair-jewellery. For these purposes 15,821 lbs. of human hair, valued at 6330*l.*, were imported into Great Britain in 1864, chiefly from the continent of Europe. There are hair-merchants in France, who collect it from the various departments, and also from Holland and Germany. In the spring of the year quite a harvest of hair is raised, chiefly in the country districts, at an average price of about five francs per lb., but choice tresses fetch more. The light colours are obtained from Germany, and the dark from France.

Hair-brushes are of many kinds, the coarsest being made of pigs' bristles, of which 2,346,135 lbs. were imported in 1864, nearly all from Russia; the average price being 2*s.* 6*d.* per lb. They are chiefly used in the manufacture of hair and clothes brushes, tooth and nail brushes, brooms, and coarse brushes. The finer sorts are made of the hair of the camel, goat, badger, dog, &c. These require great care in sorting into the different lengths. The value of artists' and painters' brushes consists in their fine points.

Horse-hair forms an important article of commerce; in 1864 as much as 15,854 cwts., of the value of 78,813*l.*, were imported from South America, Russia, and Germany. The shorter kinds are used for stuffing sofas, chairs, &c.; and horse-hair cloth is woven of hair taken from the tail. If the hair be white, as in Russian horses, it admits of being dyed green, crimson, &c., by carefully conducted processes; but black or gray horse-hairs only admit of a black dye, which is done by logwood and coppers. The

process of weaving is a tedious one, for each hair usually constitutes only one throw or thread of weft. It can only be used for the weft, except for sieve-cloth; the warp being either worsted, cotton, or linen yarn. Hair-cloth is used for covering seats of chairs, couches, also for crinoline trimming, and as a material for making bonnets. Horse-hair is also made into ropes, sacks, and bags. Cow-hair is worked into a rough yarn and woven into carpets in Germany, made into socks in Norway, and used for stuffing furniture and mixing with mortar in Britain. In 1864 the quantity of cow-hair, including that of the ox, bull, and elk, imported was 43,281 cwts., value 205,218*l.*, or about 4*l.* 15*s.* per cwt.; of this quantity 18,610 cwts. came from France, 13,397 from Hamburg, and the remainder from Holland, Russia, and Belgium.

In the coarser manufactures various substances are used as substitutes for hair, such as aloe fibre, dyed hemp and flax, and China grass. One peculiar application of hair may be briefly noticed. The Russians work up the hair of rabbits and hares into a kind of felt, press or fashion it into bowls, dishes, plates, and other articles, and varnish it thickly. The materials thus made have the appearance of *papier maché* or varnished leather, and are strong, light, and durable.

For the uses of goats' hair and camels' hair in weaving, see WOOL. The importations of hair manufactures not being goats' wool, into the United Kingdom in 1863 were valued at 21,666*l.*; France supplying 16,183*l.*, Belgium 3119*l.*, Holland 1750*l.*, and other countries 614*l.* In the same year manufactures of hair of the value of 1240*l.* being foreign manufacture, and British manufacture to the value of 18,345*l.* were exported from this country.

HAIR POWDER, is made from starch, and scented with a dry perfume. In the seventeenth century, the fashion of powdering the hair was almost universal amongst both sexes of the higher ranks of society. The hair was well greased with pomade to make the powder stick. In 1795, a tax was first put on the use of hair powder, which for a short time yielded about 20,000*l.* per annum, but it had the effect of altering the fashion by a return to natural and unpowdered hair. Some of the nobility and gentry of the present day oblige their footmen and coachmen to wear it as part of their livery, for which they have to pay, in England and Scotland, a tax of 1*l.* 3*s.* 6*d.* each.

HAIRS. In plants these are long expansions of the cuticle, chiefly intended to answer the double purpose of collecting moisture from the atmosphere, and of protecting the surface of a plant from the too powerful influence of the sun's rays. They also assist in the conveyance of certain kinds of seeds through the air, and in other cases, as in that of cotton, they are specially adapted for the use of man. That the two first purposes are those for which hairs growing on the surface of plants are intended, seems sufficiently indicated by the following facts. Hairs are seldom found on water plants, which have no occasion for absorbing organs; and when water plants are accidentally obliged to grow in dry places, they acquire them; while, on the other hand, species naturally found in hot dry places, or in arid climates, are as usually provided with them, unless in those

cases where the cuticle becomes excessively thickened. If a hairy-leaved plant is observed in dry weather, it will be found that all its hairs are weak and flaccid; but no sooner does a shower of rain fall, or the atmosphere become humid, than the hairs acquire a rigid consistence.

In all cases hairs are composed of lengthened cells of cellular tissue, extending from one or more of the cells of the cuticle. Most commonly they are quite simple, and are merely formed of several cells of equally diminishing size, placed end to end, or of a single cell.

In consequence of the hairs of plants being an extension of cellular tissue, which is naturally thin-sided, all hairs are much weaker than the tough thick-sided tubes of which woody tissue is composed. This accounts for the well-known fact that all goods manufactured from cotton are far less tough and durable than those which, like linen, are prepared from the tissue of bark or wood. When the two forms of matter are submitted to microscopical examination, the thin sides and transverse partitions of the former will usually distinguish it from the thick-sided tubes of the latter, in which no partitions are discoverable.

HAJAR. [ARABIA.]

HAKE. [MERLUCCIUS.]

HAKLUYT, RICHARD, born in 1553, studied at Christ Church, Oxford, and applied himself particularly to geography, or cosmography, as it was then called, and was made a lecturer on that subject at Oxford. About 1584 he went to Paris with Sir Edward Stafford, ambassador of Queen Elizabeth, where he remained five years. On his return to England, he was made by Sir Walter Raleigh a member of the company of gentlemen adventurers and merchants of London, for the inhabiting and planting 'of our people in Virginia,' as appears from his 'Collection of Travels,' edition of 1589, p. 815, which he published in one volume, folio, and which he afterwards enlarged and published in three volumes, folio, 1599-1600, under the title, 'The Principal Navigations and Discoveries of the English Nation, by Sea or over Land, to the remote and farthest distant quarters of the earth, at any time within the compass of these 1500 years.' Hakluyt published also or edited translations of several foreign narratives of travellers, of which a selection has been since made: 'A Selection of curious, rare, and early voyages and histories of interesting discoveries, chiefly published by Hakluyt, or at his suggestion, but not included in his celebrated compilation,' 4to., London, 1812. Hakluyt died in 1616, and was buried in Westminster Abbey.

HAKODADI, a seaport town of Japan, on a peninsula on the south shore of Yesso, in Sangar Strait. Population in 1863, 45,000. It was opened to commerce in 1858. Trade is carried on chiefly by Russian, American, and British vessels. The exports consist of wood (hardwood, pine, fir, and hinoki), combou (seaweed), gensen, awabee, dried fish, cuttle-fish, oil, and silk; imports—linen, woolen, and cotton stuffs, velvet, and sugar.

Hakodadi is 650 miles from Jeddo. It has a fine harbour, and is likely to become a place of considerable commercial importance. From a report of the British consul in Hakodadi, in 1865, it appears that there is

gradual increase of British shipping at the port, but that in consequence of the absence of precautionary measures on the part of the Japanese Government to insure the safety of vessels going to and from the port, there had been several shipwrecks. The town has been compared in position and aspect to Gibraltar and Hong Kong. The winters are extremely cold: the thermometer has been observed to register 18° below zero, and the snow lies on the ground till the close of April.

HAL, or HALLE. [BRABANT, SOUTH.]

HALBERSTADT. [MAGDEBURG.]

HALBERT or HALBERD, a battle axe, consisting of a strong wooden handle about six feet long surmounted by a sort of bill-hook, formerly used for cutting and thrusting, and also for tearing down works against which an attack was made. It was first used in England in the fifteenth century, and was borne up to the end of the eighteenth century by all sergeants of foot, artillery, and marines, and by whole companies in some regiments, called Halberdiers.

HALCYONIDE. [KINGFISHERS.]

HALDE, DU, born at Paris in 1674, entered the society of the Jesuits, and was intrusted by his superiors with the care of collecting and arranging the letters written by the missionaries of the society from various parts of the world. This employment furnished him with materials for the collection styled 'Lettres Edifiantes et Curieuses.' He also compiled, from the reports of the Jesuit missionaries and their translations of Chinese works, a full and well-digested description of that empire, which was the first published in Europe: 'Description Historique, Géographique, et Physique de l'Empire de la Chine et de la Tartarie Chinoise,' 4 vols. folio, with an atlas, Paris, 1735, reprinted soon after at the Hague, in 4 vols. 4to., and translated into English by R. Brookes, 4 vols. 8vo., London, 1736.

Du Halde was at one time secretary to Father le Tellier, confessor of Louis XIV. He died at Paris in 1743.

HALE, SIR MATTHEW, was born November 1, 1609, at Alderley, in the county of Gloucester. Both his parents having died while he was an infant, Matthew Hale was educated, under the direction of a near relation on his mother's side, by a clergyman professing puritanical principles. At the age of seventeen he was removed to Magdalen Hall, Oxford, where he plunged into great dissipation. Accidental circumstances introduced him to Serjeant Glanvil, who, perceiving his good qualities, persuaded him to apply to the study of the law. He was admitted a student of Lincoln's Inn on the 8th of November, 1629, and immediately commenced a course of arduous study. One of his companions in a debauch having been taken dangerously ill, Hale was so struck with remorse that he gave up his intemperate habits. He was called to the bar some time previous to the commencement of the civil war. He resolved not to take any part in the political dissensions and contests which then agitated the country, and he steadily kept his resolution. His neutrality was favourable to his interest as an advocate; he was engaged as counsel for the court party in many of the most important state trials, and yet he was constituted counsel to the commissioners deputed by parliament to treat with the royal commissioners as to the

reduction of Oxford. After the execution of Charles I. Hale took the engagement to be true and faithful to the Commonwealth, and accepted the appointment of one of the commissioners for reforming the law. In 1653 he was made one of the judges of the Common Bench. After having discharged the duties of his office with consummate skill and strict impartiality, he suddenly affected to feel scruples of conscience at acting as judge in criminal cases, and refused to preside in the crown courts, though he still continued to administer the law in civil cases. On the death of Cromwell, Hale refused to act under a commission from the Protector Richard. He was a member of the parliament which recalled Charles II., and was made chief baron of the exchequer in 1660, and knighted. In 1671 he was raised to the chief-justiceship of the King's Bench, where he presided with honour to himself and advantage to the public till 1675, when, from the state of his health, he resigned his office. He died from dropsy on Christmas Day, 1676.

As a lawyer Hale's reputation is high, and his integrity is unimpeached. The only spot upon his memory as a judge is the fact of his having condemned two women for witchcraft, at the assizes at Bury St. Edmund's, in the year 1665. Hale in the course of the trial avowed himself a believer in witchcraft, and the jury found the prisoners guilty, notwithstanding many impartial bystanders declared that they disbelieved the charge. The prisoners were executed.

Sir Matthew Hale was a voluminous writer, though none of his productions were printed during his life. His 'Pleas of the Crown,' 'History of the Common Law,' and some other treatises connected with the law, have been published since his death, and also several others upon scientific and religious subjects. His valuable manuscripts he bequeathed to the Society of Lincoln's Inn, and he directed that they should not be lent out or printed.

A catalogue of the manuscripts was contained in his will, and a full account and catalogue of all his works is printed in Dr. Williams' 'Life of Hale.' His life has also been written by Burnet and Roscoe, and many anecdotes relating to him are detailed by that amusing gossip Roger North, in his 'Life of Lord-Keeper Guildford.' Notices of his life will also be found in the fourth volume of the 'Biog. Brit.'

Sir Matthew Hale was twice married: first to Ann, daughter of Sir Henry Moore, by whom he had ten children; and secondly, late in life, to one of his own domestic servants.

HALEB (commonly but erroneously called ALEPPO), the capital of an eyalet of Asiatic Turkey of the same name, is situated in the north part of Syria, in 36° 11' 32" N. lat. (according to Niebuhr), 37° 9' E. long. The population is estimated at 100,000; but previous to the earthquake of 1822 it was upwards of 200,000, comprising Turks, Armenians, Greeks, Jews, Maronites, Syrians, and Europeans, the Greeks being the most numerous and the richest. The city rose to importance on the destruction of Palmyra, and became the great emporium of trade between Europe and the East. With the suburbs, it is about seven miles in circumference. The houses are of freestone, and uniformly flat-roofed. The celebrated gardens are south-east of

the city. Aleppo has a castle, a Mahommedan college, Christian schools and churches, a Roman aqueduct, which supplies it with water, large inns, warehouses, and bazaars. The town is built on four hills, called Djeleb beni el-Kaka; and is surrounded by a stone wall, and has seven gates. The condition of the city was greatly changed by the earthquake which happened in August, 1822, and which destroyed almost two-thirds of the buildings, and upwards of 20,000 inhabitants. The small river Koik runs along the west side of the town.

Before the earthquake of 1822 Haleb was supposed to possess 12,000 artisans, and was celebrated for its gold and silver lace, its manufactures of silk and cotton goods, shawls, &c. Most of these are still carried on, and there are also soap-factories, dye-works, and rope-walks. Trade is conducted by more than 100 mercantile houses. Large caravans arrive from Bagdad, Bosra, Diarbekir, Mosul, Kurdistan, and Armenia. Imports—galls, silk, wool, goats' hair, and India piece goods; cotton yarns and fabrics, cochineal, sugar, indigo, silks, woollens, and colonial goods; glass, coral, paper, velvets, steel, &c.: exports—cotton, wool, and sesame. The goods are conveyed to and from the ports of Iskanderun and Latakia by caravans of mules—all destined for the European markets, being shipped from the latter place. Consuls from all the commercial states of Europe reside at Haleb.

The ancient name of the town was Chaleb, or Chalbyon, which was changed by Seleucus Nicator into Berœa. It continued to be called by that name until its conquest by the Arabs under Abu Obeidah in 638, when its original name of Chaleb or Haleb was restored. It afterwards became the capital of an independent monarchy under the sultans of the race of Hamadan. In the latter part of the tenth century Haleb was again united to the Greek empire by the conquests of Zimisceus, emperor of Constantinople. During the crusades Haleb was subject to the Seljuke princes. In 1260 it was plundered by the Moguls, and again in 1401 by Timur. It was afterwards annexed to the dominions of the Mameluk sultans of Egypt, but was conquered by Selim I., the Turkish sultan, and has since that time been subject to the sultans of Constantinople.

The inhabitants of the eyalet only cultivate the land in the mountainous districts, which produce wheat and other sorts of corn, melons, olives, cotton, tobacco, figs, &c.: the level parts of the country are abandoned to the Kurds and Arabs. The heat of the climate is seldom oppressive, in consequence of the west winds which blow from the Mediterranean. The country is reckoned healthy. The eyalet of Haleb is watered by the Euphrates, the Orontes, and the Koik. The Koik rises near Amtab in the north, and passing by Haleb loses itself in a morass about sixteen miles south of the city.

HALES, STEPHEN, D.D., was born at Beckesbourn, in Kent, September 7, 1677, entered of Benet College, Cambridge, in 1696, was elected fellow in 1702, and, having taken holy orders, was presented about 1710 to the perpetual curacy of Teddington, near Twickenham, where, though he obtained other church preferment, he resided to the end of his life. He was elected F.R.S. in 1717, and in 1753 was admitted a foreign associate of the Académie des

Sciences, in place of Sir Hans Sloane. He died in 1761.

During his residence at Cambridge he applied himself diligently to the physical researches which continued to be his favourite pursuit through life. His first important publication was 'Vegetable Statics, or an Account of some Statical Experiments on the Sap in Vegetables,' &c.; and he made the first essays towards the modern discoveries in vegetable physiology. This work obtained for him a foreign reputation, being translated into French, Italian, Dutch, and German. 'Hæmostatics,' a similar treatise on the circulation of the blood, followed in 1733. Dr. Hales' genius was of a very practical turn: most of his numerous inventions and writings refer to some direct application of science to daily use, such as ventilation, the preservation of meat, the distillation of salt water, &c.

HALE'SIA, a genus of plants belonging to the natural order *Styracæa*. The species are trees with drooping white flowers. *H. tetraptera*, common Snowdrop-Tree, is a tree growing from 15 to 20 feet high, and is a native of South Carolina. The wood is hard and veined. It is one of the hardest and also one of the handsomest of the American deciduous trees.

HALF-PAY is an allowance made to military and naval officers, when not actively employed, as a retaining fee, the terms being very different in the navy and army. In the latter, superannuated officers retire on full-pay, and half-pay is only granted temporarily to those thrown out of employment by the reduction of the corps with which they are serving, or those who are compelled by ill-health to give up active service. The estimate of the half-pay of officers for the year 1865-66, is 324,359*l.* Colonels receive 14*s.* 6*d.* a day; lieutenant-colonels, sums varying from 8*s.* 6*d.* to 12*s.* 6*d.*; majors, 9*s.* 6*d.*; captains, 3*s.* 11*d.* to 10*s.*; lieutenants, 2*s.* 4*d.* to 5*s.* 2*d.*; cornets and ensigns, 1*s.* 10*d.* to 3*s.* 9*d.*; paymasters, 4*s.* to 15*s.*; and medical officers from 2*s.* to 30*s.* a day when on the half-pay list.

In the British navy all officers not afloat, whose ship is not in commission, are placed on the half-pay list until called upon again to serve, and as there are always more naval officers than appointments for them to fill, the non-effective list is very large. According to the navy estimates for 1865-66, the total number of naval officers on half-pay is 3516, for which the sum of 698,195*l.* is required for the year. Admirals receive sums varying from 1*l.* to 3*l.* 7*s.* per diem; captains, 10*s.* 6*d.* to 1*l.*; commanders, 8*s.* 6*d.* to 13*s.* 6*d.*; lieutenants, 4*s.* to 8*s.* 6*d.*; surgeons, 6*s.* to 18*s.* 6*d.*; and others proportionately.

HALFORD, SIR HENRY, was born on the 2nd of October, 1766, and was the son of Dr. James Vaughan, physician to the Infirmary at Leicester. Sir Henry received his early education at Rugby, and was afterwards admitted at Christ Church, Oxford; he graduated in medicine at Oxford in 1794, and was elected a fellow of the College of Physicians in the same year. Having been well introduced into London society, and being distinguished for the elegance of his manners, and having early married a daughter of Lord St. John, it was not long before his practice became considerable. He was appointed by George III. one of his physicians, and in 1809

he became possessed of a large fortune by the death of his mother's cousin, Sir Charles Halford, and changed his name from Vaughan to Halford. He was made a baronet in the same year. Sir Henry continued to hold the office of physician to George III. till the king's death, and subsequently held the same appointment under George IV., William IV., and Queen Victoria. He was appointed president of the College of Physicians in 1824, and delivered the oration on the occasion of that body removing from their old building in the city to the new one in Pall Mall.

In 1813 Sir Henry Halford descended with the Prince Regent into the royal vaults of St. George's Chapel, Windsor, where, amongst other curiosities, they discovered the head of Charles I. Of this visit and discovery Sir Henry has given an account, which is deposited in the British Museum, and is authenticated by the signature of the Prince Regent. He died on 9th March, 1844. He had been for more than twenty years president of the College of Physicians, and was mainly instrumental in establishing the evening meetings of that body. His urbanity of manners and devotion to the interests of the college have left a grateful recollection amongst the members of that corporation. His publications consist of essays and orations.

HALIBUT. [PLEURONECTIDÆ.]

HALICARNASSUS. [ANATOLIA.]

HALICHTHUS (Gr. *als*, 'the sea,' and *choiros*, 'a pig'), in Zoology, a genus of cetaceans, known as the Gray-seal. It is distinguished by a very flat head, and a deep and obliquely-truncated muzzle.

HALIDON HILL, the scene of a battle between the English and Scotch on the 19th of July, 1333, is about a mile from the town of Berwick-upon-Tweed. Edward III. was supporting the claims of Edward Balliol to the crown of Scotland, and was here met by the acting regent of Scotland with a large force. The English charging in a compact body put them to rout with immense slaughter, leaving the flower of the Scotch nobility and 11,000 men on the field, while they sustained but little loss themselves. The result was that Edward Balliol was again put in possession of the throne.

HALIFAX, a large manufacturing town, in the West Riding of the county of York, in the wapentake of Morley, was created a parliamentary borough by the Reform Act, and now sends two members to the House of Commons. Registered electors (1864), 1664. The population of the borough in 1861 was 37,014; that of the parish, which is one of the most extensive in England, and nearly as large as the whole of Rutland, 147,988. Halifax is about 200 miles from London, and 35 S.W. of York. It has first-class railway accommodation to all parts of the kingdom, and the river Calder communicates with Liverpool on one side and with Hull on the other. Coal is plentiful in the neighbourhood.

The chief articles at present manufactured at Halifax are worsted stuffs, including shalloons, tammies, calamancoes, corduroys, everlastings, moreens, shags, serges, merinos; also baizes, narrow and broad cloths, and kerseymeres. Bombazines, crapes, and other fabrics, composed of silk and worsted, are also manufactured here, and the cotton trade is carried on to a considerable extent. There are

extensive damask manufactories, and the carpet works of Crossley and Sons are the largest in the world, employing nearly 4000 persons.

The appearance of the town of Halifax is generally handsome; it contains many edifices entirely of stone; it is well lighted, and amply supplied with soft water from reservoirs about a mile north-west of the town, which were opened in 1827. The Hebble flows through the eastern parts of the town, and falls into the Calder. The scenery in the immediate vicinity of the town is of a highly interesting and beautiful character.

The parish church of Halifax is a handsome and spacious edifice of pointed Gothic architecture, erected at different dates. About eighteen other churches and chapels are subordinate to the parish church; the most notable is the magnificent Gothic church erected by Scott at the expense of Edward Ackroyd, Esq. Trinity Church is a handsome Grecian building, with Ionic pilasters, and an elegant tower surmounted by a dome: it was built in 1795. St. James' Church, built in 1831, is in the pseudo-Gothic style, with turrets at the west end. There are numerous places of worship for every denomination of dissenters, including a beautiful Independent chapel in the Gothic style, with a spire 235 feet high, erected at the cost of Sir F. Crossley, M.P. The free grammar-school at Skircoat was established in 1585 by letters-patent of Queen Elizabeth. Its property yields about 270*l.* a-year, exclusive of the school-house, garden, and offices, which are occupied by the master. The school is free for classical instruction to the sons of parishioners. There are also some smaller school charities. Waterhouse's Charity, established in 1636, provides almshouses for twelve poor widows, a stipend for the lecturer at the parish church, small yearly stipends to the curates of certain chapels of ease within the district, and various sums for other local purposes. The property of this trust has of late years greatly increased in value. The infirmary is a very noble building, which was built in 1836. It affords medical and surgical assistance both to in and out patients. The literary institutions of Halifax are, the Literary and Philosophical Society, which has an elegant hall and a museum; the Mechanics' Institution; assembly-rooms, and theatre.

There have been several modern additions to the public buildings of the town, the chief being the piece-hall, a vast quadrangle, containing 315 rooms or warehouses, in which the manufacturers keep their cloths for sale. Here most of the goods are sold to the merchant in an unfinished state. Messrs. Crossley have also recently erected some handsome almshouses, at a cost (including endowment) of 25,000*l.*; 30,000*l.* have also been expended by them on a beautiful park, designed by the late Sir J. Paxton. There is also the gorgeous church, already noticed, built and endowed by Mr. Ackroyd, at a cost of 50,000*l.*, designed by Mr. Scott; and a magnificent town-hall, designed by Sir Charles Barry (his last work, and executed by his son), with tower and spire 100 feet high. This was opened by the Prince of Wales in August, 1863; it cost 60,000*l.* In 1864 the Messrs. Crossley completed a vast orphanage, to accommodate 480 children, at an expense of about 100,000*l.*

The parish of Halifax comprises nineteen townships. The borough is governed by a mayor, ten aldermen, and thirty councillors.

In 1862 Halifax was constituted an Inland Bonding town. [INLAND BONDING TOWN.] The amount of customs revenue in 1864 was 10,090*l.*, and the trade is reported to be gradually on the increase.

Some of the refugee Flemings settled in the parish of Halifax at an early date, and stimulated the woollen manufactures of the district, if they did not originate them. Down to a recent period the dialect of the working classes strikingly resembled that of operatives in the Low Countries, especially in Friesland.

There formerly existed a very peculiar local law, by which every felon taken within the liberty, with stolen goods to the value of thirteence-pence-halfpenny, could, after three market-days, be taken to the Halifax gibbet, and be decapitated. The instrument used was somewhat similar to the guillotine, and the axe is preserved in the old prison in Jail Lane. The law was enacted as a protection to the manufacturers against the thievish propensities of their work-people, who were in the habit of robbing their employers by keeping to themselves a portion of the material which ought to have gone into the cloth, so that when the latter was manufactured it was found to be of inferior weight and body.

HALIFAX. [NOVA SCOTIA.]

HALIFAX, GEORGE MONTAGU, EARL OF, was the fourth son of George Montagu, Esq., of Horton in Northamptonshire, who was the fifth son of Henry, first earl of Manchester. He was born at Horton, on 16th April, 1661. His education was begun in the country, but he was eventually sent to Westminster School, where he was chosen a king's scholar in 1677, and whence in 1682 he was removed to Trinity College, Cambridge. He produced, on the death of Charles II., in February, 1685, some verses, which so charmed the earl of Dorset that he induced the young poet to come up to town, where he was introduced by his lordship to all the wits of his acquaintance. In 1687 he and Prior brought out in conjunction their burlesque upon Dryden's 'Hind and Panther,' entitled 'The Hind and the Panther transversed to the Story of the Country Mouse and the City Mouse.' It is preserved in the 'Supplement to the Works of the Minor Poets,' 1750, vol. i. pp. 47-82, under the head of 'Additions to the Works of the Earl of Halifax.'

Montagu appears to have some time before this entered upon his career as a politician. Johnson, in his 'Lives of the Poets,' says that 'he signed the invitation to the Prince of Orange, and sat in the convention.' In the convention parliament he sat for Malden; and he was returned for the same place to the next parliament, which met in March, 1690. It is stated to have been about the time of the Revolution that he married the Countess Dowager of Manchester: she was Anne, widow of Robert, third earl of Manchester, and daughter of Sir Christopher Yelverton, Bart.

According to Johnson, it was his intention when he formed this connection to take orders; but, afterwards altering his purpose, he purchased for 1500*l.* the place of one of the clerks of the council. He was also fortunate in his next poetical performance,

'An Epistle to Charles, Earl of Dorset, occasioned by His Majesty's Victory in Ireland,' being a celebration of the battle of the Boyne; for which King William, to whom he was introduced upon the occasion by Dorset, is said to have bestowed upon him a pension of 500*l.*

The rest of his history is that of a political character, and a patron of poets. He raised himself by his speaking to great distinction; and on the 21st of March, 1691, he was taken into office as one of the Lords of the Treasury. He was appointed Chancellor of the Exchequer on the 1st of November, 1695, and to which on the 1st of May, 1697, he conjoined that of First Lord of the Treasury. In 1695 and 1696 he obtained great credit by his management of the operation of the general recoinage of the silver money. It was in the latter of these years that, to supply a temporary circulating medium, he contrived what are called Exchequer Bills, the convenience of which species of paper, both for the government and the public, has kept it in use ever since. On the modification of the ministry in November, 1699, Montagu was removed to the auditorship of the Exchequer. In the end of the following year he was created Baron Halifax (with remainder, failing his own issue male, to George Montagu, son and heir of his eldest brother, Edward Montagu).

Lord Halifax was impeached by the new House of Commons, in April, 1701, for several alleged acts of misconduct in office, along with Lord Somers and the earls of Portland and Oxford. The question was carried in the House by a vote of 186 against 163; but the impeachment was not prosecuted, and on the 24th of June the charges were dismissed by the Lords.

In 1703, after the accession of Queen Anne, Halifax was again attacked by the Commons on the charge of having been guilty of breach of trust in the management of the public accounts while he was Chancellor of the Exchequer; but he was again protected by the Lords. Halifax first moved for the establishment of a public library, out of which eventually came the British Museum.

Having always kept up a connection with the Hanoverian family, Lord Halifax was found, on the death of Queen Anne, to be one of the nineteen persons appointed by the new king to hold the government along with the seven great officers of state till his majesty should come over. On the 14th of October, 1714, he was raised to the dignities of Earl of Halifax and Viscount Sunbury, and was restored at the same time to his former post of First Lord of the Treasury, his office of auditor of the Exchequer being given to his nephew. He died of an inflammation of the lungs on the 19th of May, 1715.

HALIOTIDÆ, *Haliotis* Tribe or Family (*Les Ormiers* of the French; Ear-shells, or Sea-ears). Of this group of Gasteropods, Linnæus records only seven species, and Mr. Dillwyn seventeen. They are now known to be very numerous.

Cuvier, in the edition of his 'Règne Animal' (1830), makes the *Ormiers* (*Haliotis* of Linnæus) the first genus of his eighth order of Gasteropods, *Scutibranchiata*. He observes that it is the only genus of the order which has its shell turbinated, and that among this sort of shells that of the *Ormiers* is remarkable for the amplitude of its aperture, its

flatness, and the smallness of the spire, which is seen from within. This form, he adds, has caused it to be compared to the ear of a quadruped. Cuvier divides the genus into the following subgenera:—1. The *Haliotids*, properly so called (*Haliotis* of Lamarck). 2. The *Padolli* of De Montfort. 3. The *Stomatia* of Lamarck. The *Ormiere*s are immediately followed by genera dismembered from the *Patellæ*, namely, *Fissurella*, *Emarginula*, and *Paramorphus*. M. De Blainville's arrangement is very similar to that of Cuvier.

Genus *Haliotis*.—In the genus *Haliotis* the shell is wonderfully brilliant, with iridescent hues, reflected from its nacreous surface. Mingled tints of purple, red, blue, and green, interchanging in various lights, produce an admirable effect. The general form of the shell is oval, more or less depressed, with a small spire having a lateral aspect posteriorly; the aperture is as large as the shell, with a continuous border; the right border is delicate; the left or columellar border is flattened, enlarged, and trenchant; along this border is a series of orifices, in lineal order, as if drilled in the shell. Muscular impression oval, and in the centre of the under side.

Animal.—One of the most ornamental of Gastropods. All round its foot to its mouth there is, at least in the more common species, a double membrane cut out into leaflets (*feuillages*) and furnished with a double row of filaments. On the outside of its long tentacles are two cylindrical pedicles for carrying the eyes. The mantle is deeply divided on the right side, and the water, which passes by means of the holes in the shell, can, through this slit, penetrate into the branchial cavity; along its edges again are also three or four filaments, which the animal can also cause to come out through these holes. The mouth is a short proboscis.

The *Haliotides* are marine and littoral in their habits. Covered with their buckler-like shield, and destitute of an operculum, they adhere by their foot to the surface of the rocks, where they creep about, feeding on herbage, which, according to Lamarck, they seek for, during fine summer nights, along the margin of the shore.

Excepting in the colder latitudes, the genus *Haliotis* is distributed through all seas; the largest, however, are natives of the hotter regions. Of these some are nearly as large as a plate, and are absolutely dazzling from the splendid iridescence of their nacre. One species, the *Haliotis tuberculata*, is common on the coasts of southern Europe, and is found in tolerable abundance on the coasts of Guernsey and Jersey, where it is used as food. Empty shells are occasionally washed up on the southern shores of our island.

Genus *Padollus*, Montfort.—This genus, says Cuvier, has the shell nearly circular, almost all the holes obliterated, and a profound furrow which follows the middle of the whorls, and is marked externally by a salient crest.

Genus *Stomatia*, Lamarck.—In this genus the shell is more hollow and with a more salient spire than in *Haliotis*; it is, moreover, destitute of perforations; in other respects it resembles that of *Haliotis*, being a link between it and certain groups of *Turbo*. The animal is far less ornamented than is that of *Haliotis*. Example, *Haliotis imperforata*.

HALISPONGIA. According to the structure and composition of the numerous species of sponges, they may be divided into genera. If, in accordance with the observations of Dr. R. Grant, we consider sponges in three groups, one having a horny tubular structure, another containing calcareous spiculae, a third containing silicious spiculae, we may adopt the three generic types, *Spongia*, *Calcispongia*, and *Halispurgia* of De Blainville.

Halispurgia is thus characterized:—Mass more or less rigid or friable, of irregular figure, porous, traversed by winding canals, which end in openings scattered over the surface; substance subcartilaginous, supported by simple silicious spiculae.

The species exhibit various external forms, incrusting, branching, or foliaceous. Dr. Fleming includes them under the title *Halichondria*.

HALL. [JAXT.]

HALL, the principal apartment of the castles and mansions of the middle ages. After the Saxon invasion of Britain, and even after the Norman conquest, the palaces and principal dwelling-houses consisted of only two rooms, the hall and the sleeping apartment. For centuries succeeding, the hall continued to be the chief room, and was generally well built and grandly decorated. The roofs, especially, were very carefully and elegantly constructed. Westminster Hall, formerly the hall of the king's palace, built by William II., and restored by Richard II., is the finest remaining example in England, being 300 feet long and 100 feet broad. At many other ancient castles and palaces the feudal hall may still be seen. The passage leading from the front door to the other rooms on the same floor, and to the staircase, in modern houses, is called the hall.

HALL MARK. The 'Hall Mark,' so called because it is impressed at the Goldsmith's Hall, is the stamp guaranteeing the degree of fineness of gold or silver. It consists of punch-marks, struck upon some conspicuous part of the article, containing respectively the initials of the maker, the head of the reigning sovereign, the lion passant, the leopard's head, and a letter to denote the year in which the plate was assayed and marked. The last is a relic of a clumsy and truly mediæval mode of declaring the date. Twenty letters, from A to U (J being excluded), complete a cycle of as many years; which ended, the same letters, but of a different type, commence a fresh cycle. By referring to the list of these letters—obtainable at the hall—the date of any piece of plate can be ascertained as far back as 1696. But the custom dates from the year 1336, and in his late work on the subject Mr. Chaffers, F.S.A., has completed the list of assay letters, by comparison with actual examples, as far back as the beginning of Elizabeth's series in 1558-59.

In London the assay year commences on the 30th May, and the date marks are continued regularly with twenty letters of the alphabet, using in succession Roman capitals, Roman smalls, and old English capitals.

The series of London date marks, commencing May 30, 1796, are as follow:—

A to U from 30th May, 1796, to 29th May, 1816.
a to u from 30th May, 1816, to 29th May, 1836.
A to A from 30th May, 1836, to 29th May, 1856.
A to U from 30th May, 1856, to 29th May, 1876.

The assay of gold and silver in England originated with the bishop of Salisbury, who was treasurer to Henry I. The first act, however, that regulated the standard was in the reign of Henry III., in 1238; and the privilege of assay was granted to the Goldsmith's Company by Edward I., in the year 1300. The leopard's head, with which all are so familiar in the English hall marks, was introduced by this charter. It is the device of the Goldsmith's Company. In 1336 the mark of the actual manufacturer was introduced, and also the assayer's mark, or variable letter, showing the year of the assay, previously alluded to. The lion passant, or 'Her Majesty's Lion,' is first mentioned in the company's records in 1597, but was not referred to in any statute till 1675.

Until the year 1798 no gold was allowed to be hall-marked if of a lower standard than twenty-two carats, *i.e.*, twenty-two parts of pure gold to two of alloy; then that of eighteen (or one quarter alloy) was permitted, as being a quality best adapted for watch-cases, chains, and jewellery designed for hard wear. 'But,' says Mr. C. W. King, in his recent work on 'Precious Stones and Precious Metals,' 'a few years ago a bill, inspired by the Birmingham interest, was smuggled through Parliament, the collective wisdom of the three kingdoms not being able to espy its true object, that of legalizing the grossest fraud. By this bill it was allowed to hall-mark gold of fifteen, of twelve, and even as base as nine carats—mere *aurichalcum* or *billon*. This concession, so unaccountably granted, has fully answered the ends of its promoters; articles of this vile alloy, strongly gilt, are sold under the time-honoured prestige of the hall mark. Few purchasers are aware of the change in the law; the carats are marked, it is true, but the minute numerals are unobserved or purposely obscured.'

Gold is impressed with all the above-named marks, excepting the lion passant, which is omitted, and in lieu thereof (on the superior standards), a crown and the figures 22 or 18 are stamped, to denote the quality. On the lower standards, no crown, but merely the figures 15, 12, or 9, and a corresponding decimal number, to indicate the quality.

The standard for silver in England (both coin and plate) from the Norman times till recently was very high, only 18 dwts. of alloy being allowed to the pound Troy, or less than one-twelfth. Under William III. this standard was for a few years raised from 11 oz. 2 dwts. to 11 oz. 10 dwts. of fine silver in the pound Troy, for plate alone. Plate of this quality is marked with a figure of Britannia, and a lion's head raised in line of the leopard's head, and the lion passant. 'But,' again says Mr. King, 'to the disgrace of our times, the bill above-mentioned also legalized a similar imposition on the buyer in the quality of silver plate, disguised by the proviso "for exportation."'

Although the larger part of English plate is stamped in London, some other towns, such as Exeter, Birmingham, Chester, Sheffield, and Newcastle, have like privileges. There are also assay offices at Dublin, Edinburgh, and Glasgow. Exeter commenced in 1701, with a cycle of twenty-four letters, and the distinguishing mark of a castle. The Birmingham cycles, containing the full twenty-six letters of the

alphabet, began in 1773, with the distinguishing mark of an anchor; for Chester, the city arms, *viz.*, three garbs; for Sheffield, a crown; and for Newcastle, the town arms, *viz.*, three towers. Scotch plate may have an earlier date. The first cycle of the Edinburgh assay office commenced under Charles II., in 1681. The distinguishing standard stamp of this office is a thistle, while Glasgow has a lion rampant. The hall mark of Edinburgh is a castle; that of Glasgow, the inartistic combination of a tree, a fish, and a bell. The Dublin assay-letters, twenty-five in number, began in the year 1646. The distinguishing stamp is a harp crowned.

As to foreign hall marks, no works have as yet been published on the subject. The great continental centres of works in the precious metals during the sixteenth and seventeenth centuries were Augsburg and Nuremberg. The first city used the stamp of a pine-apple, and Nuremberg that of a capital N; but no date-stamps seem to have been employed. The goldsmiths of Amsterdam, on the other hand, seem to have used date-letters in conjunction with the town mark (a shield containing three crosses in saltire) and the maker's mark. The marks of the French goldsmiths are more systematic, but they have not been fully investigated. A formidable list of nearly 200 French communities of goldsmiths, existing previously to 1786, and each using a proper emblem, has been compiled by MM. Lacroix and Seré in their '*L'Histoire de l'Orfèverie*.' The first ordinance that compelled the French goldsmiths to stamp their works seems to have been one of Philippe le Hardi in 1275.

The best works of reference on hall marks are 'Hall Marks on Gold and Silver Plate, with Tables of Annual Date-Letters,' &c., London, 1865; 'Precious Stones and Precious Metals' by C. W. King, London, 1865; and 'Assay-Marks' in No. 34 of the *Archæological Journal*.

HALL-MOTE, a term among the Anglo-Saxons which signified a convention of citizens in the general hall where they were in the habit of assembling. It was sometimes called *folk-mote*. At other times the name was applied to the manorial court of the lord, where disputes between the tenants were settled, as in the courts-baron of the Norman era.

HALL, BASIL, Captain, R.N., was born at Edinburgh in the year 1788. His father was Sir J. Hall, Bart. Basil Hall entered the Royal Navy in 1802; in 1808 received his first commission as lieutenant; in 1814 was promoted to the rank of commander; and in 1817 he was made a post-captain. In 1813, when acting-commander of the *Theban* on the East India station, he accompanied Sir Samuel Hood in a journey over the greater part of the island of Java. Soon after his return to England, he was appointed to the command of the *Lyra*, a small gun-brig, in which he accompanied the expedition which took out Lord Amherst as ambassador to China. While the ambassador was pursuing his journey inland to Peking, Captain Hall in the *Lyra* visited the places of greatest interest in the adjacent seas, and on his return to England in 1817 he published '*A Voyage of Discovery to the Western Coast of Corea, and the Great Loo Choo Island in the Japan Sea*.' Captain Hall was next employed on the South American station in command of the *Conway*. The period

was one of great interest to the Spanish colonies of South America.

Having returned to England early in 1823, Captain Hall published 'Extracts from a Journal written on the coasts of Chili, Peru, and Mexico, in the years 1820, 1821, and 1822.' In 1825 he married Margaret, youngest daughter of the late Sir John Hunter, Consul-general for Spain; and in April, 1827, he and his wife and child sailed for the United States, where they remained above a year, during which he travelled nearly nine thousand miles by land and water conveyances. In 1829 he published his 'Travels in North America,' 3 vols. 8vo. He next published 'Fragments of Voyages and Travels.' They form three series, each of three volumes, 12mo. In 1834 he met at Rome with a sister of Mrs. Dugald Stewart, who had married Count Purgstall, an Austrian nobleman. He accepted an invitation to visit the countess, and his book 'Schloss Heinfeld, or a Winter in Lower Styria,' was the result of his notes during his residence there. Captain Hall's last work was published at the end of the year 1841, in three volumes, under the title of 'Patchwork.' It consists of detached papers.

Captain Hall was a fellow of the Royal Societies of London and Edinburgh, and a member of the Astronomical Society of London. Having been unfortunately seized with mental alienation, he was placed in the Royal Hospital, Haslar, Portsmouth, where he died on the 11th of September, 1844.

HALL, ROBERT, was born May 2, 1764, at Arnsby, in Leicestershire. He lost his mother in 1776, and it appears to have been after this that he was sent to board at a Baptist school in Northampton, kept by the Rev. Dr. John Ryland, from which he went to the Bristol Academy, with the view of becoming a Baptist clergyman. In the autumn of 1781 he was selected by the authorities of the Bristol Academy to be sent to King's College, Aberdeen, which place he did not finally leave till May, 1785; but he had already, during the preceding summer, officiated as one of the regular pastors of the Baptist congregation at Broadmead, Bristol, in association with Dr. Caleb Evans; and in August, 1785, he was also appointed classical tutor in the Bristol Academy. His father died in 1791, and the same year a difference with Dr. Evans led to his removing from Bristol, and accepting an invitation to become pastor of the Baptist congregation at Cambridge.

He had already acquired considerable celebrity as a preacher, but it was not till now that he appeared as an author. His first publication (unless we are to reckon some anonymous contributions to a Bristol newspaper in 1786-87) was a pamphlet entitled 'Christianity consistent with a Love of Freedom, being an Answer to a Sermon by the Rev. John Clayton,' 8vo., 1791. In 1793 he published another liberal pamphlet, entitled 'An Apology for the Freedom of the Press, and for general Liberty, with Remarks on Bishop Horsley's Sermon preached 31st January, 1793.' The impression that had been made upon him, however, by the irreligious character of the French revolutionary movement was indicated in his next publication, 'Modern Infidelity considered with respect to its Influence on Society, a Sermon,' 8vo., 1800. It was the publication of this able

and eloquent sermon which first brought Hall into general notice.

In November, 1804, Hall was visited by an attack of insanity, from which he did not entirely recover for some years. His state of health made it necessary for him to resign his charge at Cambridge; but, apparently about 1807, he became minister of the Baptist chapel in Harvey Lane, Leicester, and this situation he held for nearly twenty years. He married in March, 1808. At last, in 1826, he removed to the pastoral care of his old congregation at Broadmead, Bristol; and here he remained till his death, which took place at Bristol, 21st February, 1831.

Besides occasional contributions to various dissenting periodical publications, Hall published various tracts and sermons in the last twenty years of his life, which, along with those already mentioned, have since his death been collected and reprinted in 6 vols. 8vo., London, 1831-32.

HALLAM, HENRY, an eminent historian and critic, was born in 1777, at Windsor, and educated at Eton and Christ Church, Oxford. He studied the law for some time, and became a bencher of the inner temple. His political creed was that of liberalism, but he never actively engaged in politics; co-operating, however, and that heartily, in the movement for the abolition of the slave-trade. He was one of the earliest contributors to the *Edinburgh Review*. In 1818 was published his first elaborate work, the 'View of Europe during the Middle Ages.' In 1827, the 'Constitutional History of England from the Accession of Henry VII. to the Death of George II.' was published. This work has become a standard authority, and is a text-book at the universities. In 1838 appeared the 'Introduction to the Literature of the fifteenth, sixteenth, and seventeenth centuries.' All these works have passed through numerous editions, and been translated into the languages of the leading European nations. Mr. Hallam was a fellow of the Royal Society, a member of the Society of Antiquaries, and a trustee of the British Museum. He married a daughter of Sir Abraham Elton; and of a numerous family only two sons and two daughters survived the period of adolescence. Both the sons and one daughter were prematurely cut off; the elder, Arthur Henry, who died in 1833, was the intimate friend of Alfred Tennyson, the poet, and is the subject of 'In Memoriam.' Mrs. Hallam, her eldest daughter, and remaining son died soon after. 'Bowed but not broken by these sorrows, Mr. Hallam preserved his vigorous faculties to the last, and closed his long and honoured life in calm Christian peace,' on the 22nd of January, 1859.

HALLAR, or HALLAWAR, a district of India, in the province of Gujerat. It is inclosed by the Arabian Sea, the Gulf of Cutch, &c. The surface is varied, and the soil is light, yielding wheat, millet, maize, and cotton. The district is well watered. There are manufactures of cotton fabrics, and dye-works. The area is given at 4960 square miles; and the population at 358,560.

HALLE, a town in the district of Merseburg and province of Prussian Saxony, stands on the Saale, 53 miles S. by E. from Magdeburg, and 19½ N.W. from Leipzig, by the railway that unites those two cities. Population (1861), civil, 41,507; military, 1469. It

is celebrated chiefly for its salt-springs and salt-works, and as the seat of a university. It consists of three towns—Halle itself with five suburbs, and Glaucha, and Neumarkt, which have magistrates of their own. The university was founded in 1694, and united in 1815 with that of Wittenberg. It possesses a valuable library, museum, anatomical theatre, chemical laboratory, botanic garden, and observatory. Outside the walls is a monument to the Germans who fell in the battle of Leipzig. The university buildings, the churches of St. Mary, St. Ulrich, and St. Maurice, the cathedral, the Red Tower in the market-place, and the town-hall, are the most remarkable structures. The ancient castle of Moritzburg was reduced to a ruinous condition in the Thirty Years' War, and only a wing now remains. Halle possesses many educational and charitable institutions; foremost amongst which is the Francke Institution, embracing an orphan house and schools. The town is distinguished by the activity of its printing-presses, and is rapidly becoming an important railway centre. Its name is derived from *Hall*, an old word for 'salt,' in consequence of the numerous brine springs of the place and neighbourhood, from which a large quantity (from 225,000 to 300,000 cwt.) of salt is made annually, by a peculiar class of workmen, called the 'Hallores.' The town is the birthplace of Handel and Michaelis, and many eminent names are associated with its University.

HALLE. [BRABANTE, SOUTH.]

HALLEIN. [SALZBURG.]

HALLELUJAH, properly *Hallelu-yah*, *Halleluia*, or *Alleluia*, a Hebrew compound word, which means 'praise ye Yah or Yehovah,' was used by the Jews in songs of praise and in solemn thanksgivings to God. It was retained in the Greek and Latin liturgies in the original Hebrew; but in the prayer-book of the Church of England, its English equivalent, 'Praise ye the Lord,' is used.

HALLER, ALBERT VON, was born at Berne, October 16, 1708, of an ancient and respectable family. His father, Nicholas Emmanuel von Haller, was an advocate. In his early life Haller was feeble and delicate. His father had intended him for the church, but, his own inclination leading him to the study of physic, he went in 1723 to the University of Tübingen. Being but little satisfied with his progress here, he resorted in 1725 to Leyden, where the zeal and talent of the professors afforded him an opportunity of pursuing his studies in a manner more accordant with his wishes. At this university Boerhaave was then in the height of his fame, attended by 120 pupils, whose instruction was his greatest delight; and Albinus was delivering the lectures on anatomy and surgery. At the end of 1726 he offered himself for his doctor's degree, and delivered his thesis '*De Ductu Salivali Coschwiziano*,' which he showed to be merely a blood-vessel. In 1727 he visited London, where he became acquainted with Sir Hans Sloane and Cheselden; thence he went to Oxford, and thence to Paris, whence, having pursued his anatomical and surgical studies for some time under Winslow and Le Dran, he went to Basel to study mathematics under Bernoulli, and then returned to his native country, and began to practise as a physician. In 1735 he was appointed physician to the hospital at Berne, and soon after princi-

pal librarian to the large public collection of books and medals; but these offices he did not hold long, for in the following year he was offered the professorship of medicine, anatomy, botany, and surgery, at Göttingen, by George II., which after some hesitation he accepted. Having declined practising, he devoted himself to the duties of his office with the greatest zeal, and especially exerted himself to increase the facilities for the study of anatomy. During eighteen years that he retained this appointment, while fully discharging all his laborious duties, he was a constant contributor to the different scientific Transactions. In 1747 he published the first edition of his '*Primæ Linæ Physiologiæ*,' which he had that year used as the ground-work of his lectures, having previously employed the '*Institutiones*' of Boerhaave. In 1751 the Royal Society of Göttingen was established, and Haller, at whose house the first meeting took place, was appointed perpetual president. To their Transactions, of which the first volume appeared shortly after under the title of '*Commentarii Societatis Regiæ Scientiarum Göttingensis*,' he was a constant contributor, even after 1753, when, in consequence of the delicate state of his health, being obliged to leave Göttingen, he retired to Berne. Here he resided during the rest of his life, constantly occupied in the publication of his most important and voluminous works, in the cultivation of the science of his profession and of general literature, and in the active and honourable discharge of various duties in the service of the republic, in which he at all times strenuously advocated the cause of the aristocracy. He died in October, 1777, in the enjoyment of the highest reputation, both as a citizen, a scholar, and a philosopher, his literary labours ceasing only with his life.

Haller was fortunate in receiving the high honours which he deserved during his lifetime. In 1739 he was appointed physician to the king of England. In 1743 he was elected a fellow of the Royal Society of London, and at different times subsequently of all the scientific societies of Europe. When George II. visited Göttingen in 1748, he was ennobled by the emperor: he was invited by Frederick the Great to settle in Berlin, with a handsome salary, to which no duties were attached, and was offered a professorship at Oxford and at Utrecht. He enjoyed throughout his life the friendship and esteem of the most eminent of his contemporaries throughout Europe.

Some idea of the extent of the works of Haller may be formed from the fact that the titles of nearly two hundred treatises published by him from 1727 to 1777 are given by Senebier in his '*Eloge*' of Haller, and that this list does not profess to be complete. He is unanimously received as the father of modern physiology, whose history commences with his writings. He was the first to investigate independently the laws of the animal economy, which had before been studied only in connection with the prevailing mechanical and chemical or metaphysical theories of the day. Commencing with a sound knowledge of anatomy and of the structure of the organs in the dead body, he sought experimentally and systematically to discover the laws which governed their actions during life, proceeding from the most simple to the most complex phenomena. Excluding all the metaphysical explanations which Van Helmont

and Stahl had invented, and all those deduced from mechanics and chemistry which were not clearly sufficient for the phenomena ascribed to them, he sought for powers peculiar to the living body, which he believed must govern the actions which he found occurring only in it. These he thought might be restricted to two—sensibility and irritability; the former seated in the brain and nerves, the latter in muscular fibre. But it was soon shown that the restriction of the vital powers to the two, as defined by Haller, was much too exclusive, for that there were many parts which, though they gave no evidence of possessing either of them, were not the less alive, while others to which Haller refused these properties gave sufficient demonstration of possessing them when excited by other and appropriate stimuli. Hence first originated the discovery of the fact that for the action of each organ a peculiar stimulus is required, and that each tissue has, what Bichat, who illustrated it most completely, called a *vie propre*.

HALLER, JOHANN, a German sculptor, was born at Innsbruck in 1792. He studied in the academy of Munich, and in his third year obtained the prize for a statue of Theseus raising the rock to discover the sandal of his father. He executed many works in Munich for the king of Bavaria; the principal of which are the models of the sculptures for the pediment of the Glyptothek, representing Pallas Ergane ('Εργάνη, the 'worker'), from a design by Wagner; the six colossal statues of the niches in the front of the same building; and the Caryatides of the royal box of the great theatre at Munich; besides a basso-relievo in the interior of the Glyptothek after a design by Cornelius, representing the Fall of the Giants; and many busts of eminent men, some of a colossal size. He executed the bust of William III. of England for the Walhalla. He died in 1826, aged only thirty-three. He studied some time at Rome.

HALLEY, EDMUND, was born October 29, 1656, at Haggerston, near London, at a country-house belonging to his father, who was a soap-boiler in London. He was educated at St. Paul's School, under the care of Dr. Gale, and was placed at Queen's College, Oxford, in 1673, being then possessed of much erudition for his age, and a strong turn for observation, as appears by his having discovered for himself before he left school the alteration in the variation of the magnetic needle. At the university, being well supplied with instruments by his father, he began to apply himself to astronomy, and before he reached the age of twenty he had given (in the 'Phil. Trans.') a memoir on the problem of Kepler, had invented a method of constructing the phases of a solar eclipse, and had made many observations, particularly of Jupiter and Saturn. Finding, however, that nothing could be done in planetary astronomy without more correct tables of the stars, and relying upon Flamsteed and Hevelius for the amelioration of the northern catalogues, he determined, with his father's consent and assistance, to appropriate to himself the task of forming a catalogue of the southern hemisphere. Furnished with a recommendation from Charles II. to the East India Company, he set sail for St. Helena in November, 1676, and remained there two years. His 'Catalogus Stellarum Australium,' published in 1679, was the

result of this voyage, and contains, besides the positions of 350 stars, some other points of interest, particularly an observation of the transit of Mercury over the sun's disc, and a hint that such observations might be employed to determine the sun's parallax (afterwards so successfully carried into effect with the planet Venus). He also notices the increased curvature of the moon's orbit when in quadratures, which was afterwards explained by Newton. In his voyage out he had observed the fact that the oscillations of a pendulum increase in duration as the instrument approaches the equator.

On his return from St. Helena, the king granted him a mandamus to the University of Oxford for the degree of Master of Arts, and he was elected a fellow of the Royal Society. This body sent him to Danzig in 1679 to judge of the observations of Hevelius, who maintained the superior accuracy of instruments with simple sights in opposition to Hook, who advocated the use of the telescope. Halley was a man of rapid movements: in November, 1678, he returned from St. Helena; in May, 1679, he set out for Danzig, having in the interval published his catalogue, and procured his Oxford degree, and admission to the Royal Society. He returned from Danzig in July, and remained at home till the end of 1680, at which time he set out on a continental tour, accompanied by his schoolfellow Mr. Nelson, since well known as the author of a work on the Feasts and Fasts. In December, being on the road to Paris, he saw the celebrated comet of 1680 in its return from perihelion, being the first who perceived it since it was lost in the preceding month. This body he observed with Cassini at Paris, and the observations thus made are remarkable as forming part of the foundation upon which Newton, in the 'Principia,' verified his deduction of a comet's orbit from the theory of gravitation. He returned to England at the end of 1681, and in 1682 married the daughter of Mr. Tooke, auditor of the Exchequer, with whom he lived fifty-five years. He resided at Islington till 1696, and in 1683 published his theory of the variation of the magnet, followed by other papers in subsequent years, containing ingenious speculations, now forgotten. His astronomical occupations during this period consisted chiefly of lunar observations and comparisons. He was strongly of opinion that the moon would, when sufficiently known, furnish the means of finding the longitude, and at this period it seems that he had formed the idea of observing that body through a whole revolution of the nodes.

Among other objects of speculation, he had considered the law of attraction, which he imagined must be as the inverse square of the distance. Having applied in vain to Hook and Wren for assistance in the mathematical part of the problem, he heard of Newton, and paid him a visit at Cambridge. Finding all he wanted among the papers of his new friend, he never rested until he had persuaded Newton to publish the 'Principia,' of which he superintended the printing, and supplied the well-known copy of Latin verses which stand at the beginning. In 1691 he was a candidate for the Savilian professorship, which he lost, according to Whiston, on account of his avowed disbelief of the Bible.

In 1698 King William, who had heard of his

magnetic theory, gave him the commission of captain in the navy, with the command of a small vessel, and instructions to observe the variation of the magnet, and the longitude and latitude of places in the American settlements, and to attempt the discovery of land south of the Western Ocean. He set out in November, but was compelled to return by the insubordination of his first lieutenant. Having tried this officer by a court-martial, he set out again in September, with the same ship and another, observed in many parts of the Atlantic as far as the ice would permit, touched at the Canaries, Madeira, Cape de Verd Islands, St. Helena, Brazil, Barbadoes, and returned, September, 1700, without having lost a man by sickness during the whole voyage. He published in 1701 a chart of the variation of the magnet in all seas of the known world, and immediately afterwards sailed to survey the coasts of the Channel, of which he also published a chart. He was then twice successively ordered to the coast of the Adriatic, to assist in the formation and repairs of harbours in the emperor's dominions, and returned to England in November, 1703, just in time to succeed Dr. Wallis, who had died a few weeks before, in the Savilian chair of geometry at Oxford.

If Halley was active and energetic, he was no less universal. The captain-professor found an unfinished translation by Dr. Bernard of a tract of Apollonius, and, though he did not understand Arabic, undertook to complete the work. We must also mention the splendid edition of the whole of Apollonius, published in 1710.

The 'Miscellanea Curiosa,' a collection of pieces, mostly from the 'Philosophical Transactions,' many of them by himself, was superintended by him, and published in 1708.

From the manner in which his name is mixed up with the affair of Flamsteed, he must have resided in town for some years previous to 1713. [FLAMSTEED.] In the article cited we have called Flamsteed's work the *Principia* of practical astronomy; and it were to be wished that the connection of Halley with the printing of this one had been as creditable as that which links his name with the '*Principia*' of Newton. It is difficult to say to what extent Halley was involved in originating any of the unworthy proceedings to which we allude; and we must protest against his being made a scapegoat for Newton, in which position even Flamsteed seemed inclined to place him, as well as several more recent writers on the controversy. Neither the position nor the character of Halley renders it likely that he would prefer making a tool of Newton to any direct mode of aggression. The committee appointed by Prince George of Denmark must bear the blame of all the formal proceedings; and in that committee the name of Halley is not found, though it is on the list of those who published the '*Commercium Epistolicum*,' a position which we cannot defend.

At the beginning of 1720, after the death of Flamsteed, Halley was appointed astronomer-royal. [GREENWICH OBSERVATORY.] He died January 14, 1741-42, in the eighty-sixth year of his age.

Among the Englishmen of his day Halley stands second only to Newton, and probably for many years after the publication of the '*Principia*' he was the only one who could and would rightly appreciate

the character and coming utility of that memorable work.

In astronomy we owe to Halley—1. The discovery and the detection of the amount of what is called the *long inequality* of Jupiter and Saturn, which he confidently expected would be shown to be a consequence of the law of gravitation, as was afterwards done. 2. The detection, by comparison of ancient and modern observations of eclipses, of the slow acceleration of the moon's mean motion. 3. The first prediction of the return of a comet. [HALLEY'S COMET.] 4. The explanation of the appearance of Venus in the daytime at particular seasons, arising out of the now well-known method of estimating the brilliancy of the planet. 5. The recommendation to observe the transit of Venus for the determination of the sun's parallax.

The following list of the most remarkable labours of Halley out of astronomy, arranged in the order of publication, will instruct the reader to what articles to look for further information:—1. On the variation of the compass. 2. The law according to which the mercury falls in the barometer while the instrument ascends, being the first application of this instrument to the measurement of heights. 3. Theory of the trade-winds. 4. Construction of equations of the third and fourth degree. 5. Estimation of the quantity of vapour raised from the sea. 6. Inquiry into the point at which Julius Cæsar made his entry into Britain. 7. Tables of mortality, from observations made at Breslau, the first of the kind constructed. 8. Application of algebra to the problem of lenses. 9. Method of constructing logarithms, a celebrated paper, reprinted in Sherwin's '*Logarithms*.' 10. Improvements in the diving-bell. Those papers only have been cited which refer to points on which Halley's name is inseparably connected with the history of the progress of science.

HALLEY'S COMET, the first of the comets which was proved to be a constituent part of the solar system, and to revolve regularly round the sun, deriving its name from HALLEY, the astronomer, who first discovered that it had made several revolutions within the era of correct astronomical observation, and predicted the year of its return.

The '*Astronomiæ Cometice Synopsis*' of Halley was published in the '*Philosophical Transactions*' for 1705, and in several other forms. This work was a consequence of the '*Principia*' of Newton, in which the method of applying Kepler's laws to the computation of the parabolic orbit of comets, the idea of the possibility of a periodic comet, and even an implied assertion that such things would be discovered, is to be found. Halley, acting upon this hint, collected the observations of all such comets as had been observed with any degree of accuracy up to the year 1700.

On looking over the list, it needed only a glance to see that three of these comets (in 1531, 1607, and 1682) exhibited very nearly the same orbit, and that the intervals of the appearances were very nearly the same.

The interval between the perihelion passages of the first and second comet is fifteen months longer than that between the second and third, which might have puzzled a person not acquainted with the '*Principia*.' But the disturbing action of the planets,

which has since been so successfully computed that the motion of this body is now much better known than was that of the moon in the time of Halley, immediately suggested itself. He announced, accordingly, the return of the comet about the year 1758.

In the latest edition of the 'Synopsis' Halley examined the elements of the comet's orbit further, and repeated his prediction still more confidently, desiring that all would remember that its author was an Englishman.

The prediction of Halley caused various astronomers to compute orbits of the coming comet, but none of these took into account the perturbations caused by the planets. In 1757 Clairaut and Lalande undertook the enormous labour of computing the effect of the perturbations of the principal planets through a period of 150 years. Assisted by Madame Lepaute, wife of a well-known watchmaker of that name, Lalande performed the drudgery of the process, while Clairaut, the first who extended Newton's application of his theory, applied the results. The consequence was, that in November, 1758, when the comet was already expected, the announcement was made that it would arrive at its perihelion within a month, one way or the other, of April 13, 1759. The announcement of Clairaut was just in time, for on December 25, 1758, George Palitzsch, a farmer and amateur astronomer in the neighbourhood of Dresden, detected the comet. It was afterwards repeatedly observed in various parts of Europe, but it is not on record that any one saw it with the naked eye, nor was its position at all favourable for that purpose. Various orbits were computed, but no one seemed inclined to undertake the task of applying the corrections for perturbation, so as to predict the perihelion place for 1835. The comet slept in peace therefore until the improvement of methods of computing the perturbations, and the approach of a new appearance.

The comet was first seen at Rome on the 5th of August, 1835, at the observatory of the Roman college. From that time it continued to be observed till the end of the year in Europe, and through a great part of the ensuing spring in the southern hemisphere. During a part of the time it was distinctly visible to the naked eye. The number of good observations which were procured greatly exceeded, as might be supposed, those made on any previous occasion.

HALLUIN. [NORD.]

HALO is a circular band of faintly coloured light which is occasionally seen surrounding the disc of the sun or moon at a distance from it equal to 22 or 23 degrees. The colours of the solar halo are such as are observed in the rainbow, but they are less bright, and they do not always, in the halo, follow the same order as in the bow. The lunar halo in general appears to be white, but it is at times tinted with pale green or red. Often about either luminary the halo is double, consisting of two concentric circular bands, the exterior one being broader than the other.

When a mist or a thin cloud is between the sun or moon and a spectator, there is frequently observed an ill-defined circle of coloured light immediately surrounding the disc of the luminary; this is called a corona; it sometimes appears when a halo is also

seen, but it is more commonly observed without such accompaniment. It is supposed to be produced by the refractions of light in the globules of water which are suspended in the atmosphere between the spectator and the luminary.

It may be observed, in this place, that images of the sun have been occasionally seen as if by reflection from some cloud, the sun being near the horizon: these are called anthelia; and they are supposed to be produced by the reflections of light in prisms of ice having their axes in vertical positions.

Halos are frequently accompanied by a horizontal ring or band of whitish light passing through the sun or moon; and at times a similar band appears in the direction of a diameter perpendicular to the horizon. At the intersections of these bands with the halo are sometimes seen images of the sun or moon, which are ill defined and less bright than the true disc of the celestial body; these, when the halo is formed about the sun, are called parhelia; and, when about the moon, paraselenæ. Occasionally, also, segments of circles or branches of curves of contrary flexure, proceed from these images of the sun or moon so as to assume the appearance of wings or tails.

Many remarkable phenomena of this kind have at various times been observed: in the 'History of England,' by Matthew Paris, there is a description of a halo with four false suns, which is stated to have been seen in the year 1233, on the borders of Herefordshire and Worcestershire. In 1586 Rothman observed at Cassel, soon after sunrise, a false sun above, and one below the true sun, all being in one vertical line; and in 1661 Hevelius at Danzig observed a double halo accompanied by three false suns, and by several segmental bands of light, two of which had false suns at their places of intersection. In the last mentioned year Hevelius also observed a halo, with two paraselenæ and a double corona encircling the body of the moon; and a very remarkable halo was seen by Sir Henry Englefield at Richmond, in 1802. ('Journal of the Royal Institution,' vol. ii.) Besides these, many such phenomena have been observed in Europe, in the United States, and in Canada; and Captain Parry observed and measured several during his voyages to the arctic regions. One of these was a great double halo with a horizontal circle of light, at the intersections of which with the interior halo were parhelia; and there were segments of circles both at the upper extremities of the two halos and at the lower extremities of the exterior one, the latter being incomplete. Above the sun, and between the two halos, was a small portion of a third halo, which appeared to be elliptical; and the space between the two segments was extremely brilliant, in consequence of strong reflections of the sun's rays from the snow which floated in the atmosphere.

In the tropical regions coloured halos are frequent and brilliant; and, near the equator, Humboldt has observed small ones surrounding the planet Venus.

The explanation which has been given of the halo by Mariotte and Dr. Young is nearly as follows:—Between the spectator and the sun innumerable crystals of snow or ice, having nearly the form of equilateral prisms, may exist in the air, in all possible positions: of these vast numbers many have their transverse sections in planes nearly passing through the sun and spectator; and it will follow, after two

refractions at the edges, that the deviation of the refracted from the incident ray, at the eye of the observer, is about equal to the semi-diameter of the halo. This taking place in all planes so passing, a circle of refracted light is seen. Mr. Cavendish suggests that the exterior halo may be produced by the two refractions which a ray would undergo in passing through a face and one end of a prism, that is, through two surfaces which are at right angles to one another.

Plates of ice disposed so as to reflect the sun's light in a vertical plane may be the cause of the column which is sometimes seen to form a vertical diameter of a halo; and the blending of the reflected rays with the rays refracted from the sides of the prisms, at the places where the horizontal and vertical bands of light intersect the halo, is, apparently, the cause of the parhelia which are very generally observed in those parts of the halo. When the transverse sections of the refracting prisms deviate from a plane passing through the observer, towards the right or left, the axes being horizontal, there will be produced a curvilinear band of light, like a wing, inclining upwards on either side of a parheliion.

A beautiful optical instrument called a *haloscope* has been invented in France for the exhibition of all the phenomena connected with halos, such as the corona, anthelia, parhelia, &c. It consists of prisms, sheets of plate-glass, and mirrors, mounted on an axis, and having a rotatory motion; and differently arranged to show the various circles.

(See Plate 'Halos' for illustrations of numerous forms of halos, parhelia, and other kindred meteorological phenomena.)

HALONIA, a genus of fossil plants, allied to *Lepidodendron*, and occurring in the coal formation.

HALORAGÆE, a small group of exogenous plants, many of which inhabit watery places, and all of which have minute inconspicuous flowers. They are often considered to form a peculiar section of *Onagraceæ*, or, if separated from that order, are at least stationed in the immediate vicinity of it. Upon this supposition, they are looked upon as an imperfect condition of the onagraceous type.

HALS, FRANCIS, an eminent portrait-painter, born at Mechlin, 1584; died in 1666. He devoted himself almost exclusively to portrait-painting, and in that department no artist of his time was superior to him except Vandyck, and very few could be compared with him.

HALSTED. [ESSEX.]

HALYS. [KIZIL ERMAK.]

HALYSITES, the name given by Fischer to a genus of fossil corals, synonymous with *Catenipora* of Goldfuss.

HAM, EAST and WEST. [ESSEX.]

HAM. [SOMME.]

HAMADAN. [ECBATANA.]

HAMADRYADES (Gr. *ama*, 'together,' and *drus*, 'an oak'), a name frequently mentioned by the Greek and Roman poets, and applied to certain woodland deities who were presumed to be the divinities presiding over woods and forests, or even over particular trees with which they were co-existent.

HAMAMELA'CEÆ, or HAMAMELI'DEÆ, a very small group of woody exogenous plants. There are only three genera in the gardens of this country,

Hamamelis, *Trichocladus*, *Fothergilla*. Some of the species are large forest trees, affording good timber, but nothing is known of any other useful property in the order.

HAMBURG, a large city in Germany, the most important centre of commerce in that country, is situated in 53° 32' 51" N. lat., 9° 58' 37" E. long., 184 miles by railway N.W. from Berlin, and about 70 miles from the mouth of the Elbe. Its origin is attributed to Charlemagne. The founder chose for its site the most elevated spot on the north bank of the Elbe and the east bank of the Alster, about 75 miles from the German Ocean. It was several times destroyed by the neighbouring barbarians, yet it always recovered, and had attained considerable commercial importance at the beginning of the twelfth century. In the thirteenth century it concurred in the formation of the Hanseatic League. [HANSEATIC LEAGUE.] By degrees it extended widely on both sides of the Alster. Its rights as an estate of the empire were long contested by the Danish kings; and it was not until 1618 that they were recognized. It did not, however, obtain a seat or vote in the Diet of the German empire till 1770. From 1802 till 1815 Hamburg was scarcely free for a year from French domination and exaction, and it suffered most severely. In 1815 it joined the German Confederation as a free Hanseatic city. For all its severe sufferings, including the robbery of the bank, a very inadequate indemnity was obtained from France at the peace; but the public spirit of the inhabitants, its internal resources, and its favourable situation, have gradually restored it to more than its former prosperity.

The territory of Hamburg, including the area of the city, is about 148 square miles, bounded on the south by the Elbe, and on the other sides by the Danish territories. It has likewise some islands in the Elbe, some parcels of land on the Hanoverian side of the river, and the bailiwick of Ritzebüttel at the mouth of the Elbe, in which is the harbour of Cuxhaven. Conjointly with Lübeck it has the bailiwick of Bergedorf, and the districts called Vierländen, 16 miles from Hamburg. The population of the territory in 1861 was 229,941; of the city, with the suburbs, 178,000, of whom 10,000 were Jews—the latter being amongst the wealthiest and most energetic members of the community. The majority of the inhabitants are Lutherans.

The present constitution of Hamburg was published on the 28th of September, 1860, and came in force on the 1st of January, 1861. According to the terms of this fundamental law, the Government—*Staatsgewalt*—is intrusted, in common, to two chambers of representatives—the Senate, and the Bürgerschaft, or House of Burgesses. The Senate, which exercises chiefly, but not entirely, the executive power, is composed of eighteen members, one-half of which number must have studied jurisprudence, while seven of the remaining nine must belong to the class of merchants. The members of the Senate are elected for life by the House of Burgesses; but a senator is at liberty to retire at the end of six years. A first and second burgomaster, chosen annually in secret ballot, presides over the meetings of the Senate. No burgomaster can be in office longer than two years, and no member of the Senate is

allowed to hold any public office whatever. The House of Burgesses consists of 192 members, eighty-four of whom are elected in secret ballot by the votes of all tax-paying citizens. Of the remaining 108 members, forty-eight are chosen, also by ballot, by the owners of house property in the city valued at 3000 marks, or 187*l.*, over and above the amount for which they are taxed; while the other sixty members are deputed by various guilds, corporations, and courts of justice. All the members of the House of Burgesses are chosen for six years, in such a manner that every three years new elections take place for one-half the number. The House of Burgesses is represented, in permanence, by a Bürger-Ausschuss, or committee of the house, consisting of twenty deputies, of which no more than five are allowed to be members of the legal profession. It is the special duty of the committee to watch the proceedings of the Senate, and the general execution of the articles of the constitution, including the laws voted by the House of Burgesses. In all matters of legislation, except taxation, the Senate has a veto; and in case of a constitutional conflict, recourse is had to an assembly of arbitrators, chosen in equal parts from the Senate and the House of Burgesses.

The annual revenue and expenditure of the city is each about 620,000*l.* The public debt is about 3,500,000*l.* A considerable part of this sum was incurred after the great fire in 1842, and spent in rebuilding the city on a new and improved plan. The whole damage caused by the conflagration—which laid more than 5000 buildings in ashes—was estimated at the time at 90,000,000 thalers, or nearly 36,000,000*l.* sterling.

The troops in the service of the state are divided into two classes, namely, the standing army and the Bürgermilitär, or militia of burgesses. The first-named, which is formed by enlistment for periods of six years, consists of two battalions of infantry, numbering 1686 men; one company of Jägers, of 120 men; a detachment of pioneers, of about fifty; and two companies of dragoons, of 336 men. These form the sum total of troops which Hamburg has to contribute to the army of the Confederation. The militia of burgesses amounts to more than 10,000 men, divided into nine battalions of infantry, one battalion of Jägers, two troops of cavalry, and three companies of artillery. Every citizen, not exempt on account of bad health, is liable to service, from the twenty-first to the fortieth year.

Hamburg is divided into the old and new town; but since the great fire in 1842, when fully one-fourth of the city was destroyed, including most of its public buildings, it has been greatly altered in appearance; and the present city is remarkable for its fine, open, well-lighted, and well-drained streets, and its spacious and lofty houses. The arm of the Elbe, next the town, is narrow, but the two harbours are capable of receiving a considerable number of ships. The old town is so intersected with canals as to resemble a Dutch city; the canals are filled chiefly by the Elbe, but partly by the Alster, and almost all the warehouses are close to them. The Alster forms on the north side of the town a fine basin, on the south side of which is the finest line of houses in the city, with a spacious walk, the Jungfernstieg, planted with trees. This favourite prome-

nade has been continued along the west side of the basin, so as to join the ramparts, the whole of which are beautifully laid out as a public garden and promenade all round the city. North of this Inner Alster is the Outer Alster, a very large basin, on the banks of which are numerous fine country seats. The place of worship most worthy of notice is the great Church of St. Michael, begun in 1751, and completed in 1762, except the spire, which was not erected till 1778. This church, built by Sonnin, is the pride of Hamburg; it is capable of accommodating 2000 persons: the height of the steeple is said to be 423½ feet. The other churches are not remarkable. The exchange—the most commodious in Europe—the bank, the observatory, and the theatres, are among the chief public buildings. The charitable and scholastic institutions are numerous, and on a most liberal scale. The former include an infirmary for between 4000 and 5000 patients; an hospital, for the support of 142 aged persons; and a large orphan school, for the improvement of depraved and abandoned children. There are two educational institutions supported by the state, designed to qualify young men for the University, and a gymnasium. There is also a fine botanical garden. Hamburg has been the birthplace of many learned men, and the chosen residence of many others. Its numerous literary institutions, its private collections of paintings, the general taste for music, the fondness for the study of foreign languages, prove that the whole attention of the inhabitants is not absorbed by thirst of gain. The principal public library, called the City Library, contains nearly 200,000 volumes, besides 5000 volumes of MSS.

Hamburg is essentially a commercial city, its port being the main channel of communication between North Germany and foreign countries. At high tide vessels can come up the Elbe and unload in the harbours; while by means of the various canals (crossed by eighty-four bridges), lighters can carry the cargoes into the very heart of the city. Hamburg ranks as the greatest emporium of trade on the Continent, and, next to London, has the largest money-exchange transactions in Europe. It is also one of the principal ports for transatlantic emigration, and the centre of a very extensive business in marine insurances.

The number of ships (sailing vessels and steamers) which arrived at the port of Hamburg from all parts of the world in 1864, was 5012—their total burthen being 465,509 commercial lasts. (A last is equal to 6000 lbs.) The number of vessels which left the port in the same year was 5006, of 463,074 lasts burthen. Of the entries, no less than 2247 were from Great Britain—about half, however, being colliers. But in order to form a complete view of the foreign trade of the 'Free City,' it will be necessary to add to the number of ships arrived at Hamburg those which came to the neighbouring ports of Altona and Harburg. It has already been stated that the Hamburg ships in 1864 amounted to 5012, of the total burthen of 465,909 commercial lasts of 6000 lbs. The number of those which discharged at Altona in the same year was 1316, burthen 58,066 Danish lasts, of 5200 lbs.; the number which discharged at Harburg was 890, burthen 39,722 lasts, of 4000 lbs. The total number of sea-

going ships which arrived in the Elbe in the year was, therefore, 7218; and their total burthen, reduced to commercial lasts, was 542,747 lasts, or 1,628,241 tons, English measure.

The number of sea-going ships registered as belonging to the port of Hamburg in 1865, was 530; and their total burthen, 79,380 commercial lasts, including twenty-one steamers of the burthen of 6252 commercial lasts, and with 3725 horse-power. The Hamburg-American Steam-Packet Company has six large screw steamers running regularly between Hamburg and New York, and continues to carry on its business with great success. The ships registered at Altona amounted at the close of 1864 to fifty-seven in number, their total burthen being 7069 Danish lasts.

The imports in 1864 were valued at about 55,000,000*l.*, chiefly from Great Britain, Germany (by land carriage, railway, and the river), America, France, and the West Indies.

The amount of the exports cannot be ascertained, inasmuch as no official account of them has been kept since 1856, when the export duty was abolished.

The official statement of British trade and navigation does not furnish a separate account for Hamburg; but enables us to give the imports and exports into and from the Hanse Towns, viz.—Hamburg, Bremen, and Lubeck. About five-sixths belong to Hamburg.

The total value of the exports from the Hanse Towns to the United Kingdom in 1863 amounted to 6,946,234*l.* There has been little variation for some years. The following table shows the principal articles, with their values:—

Animals—oxen and bulls, ...	12,862 number	£209,683
" sheep, ...	165,828 "	220,642
Bacon, ...	104,531 cwts.	284,300
Butter, ...	160,167 "	800,978
Cheese, ...	32,805 "	85,116
Corn—wheat, ...	73,013 qrs.	159,414
" barley, ...	171,361 "	255,400
" wheatmeal and flour, ...	306,217 cwts.	229,773
Cotton manufactures, ...	—	103,709
Hops, ...	41,962 "	199,539
Pork, salted, ...	39,998 "	95,554
Seed, clover, ...	66,990 "	176,758

Woolen yarn, ...	1,744,556 "	412,334

Minor articles sent to the English market comprise arms, beads of glass, beef, bones, books, china-ware, fruit, glass-ware, hair, hides, lard, musical instruments, paper, plumbago, rags, skins, spirits, and toys. A considerable quantity of cheap and often fictitious 'wine' and brandy is exported from Hamburg to this country; and in many cases the Commissioners of customs have recently refused to allow such to be passed as wine, and ordered it to be rated at what it has been really proved to be, 'mixed spirits.' Most of the plain spirit used to fortify wine in bond is also exported to England from Hamburg.

The imports from Great Britain into Hamburg, Bremen, and Lübeck, in 1863, amounted to the enormous sum of 17,132,717*l.*, an increase of four millions as compared with 1860. The produce and manufactures of the United Kingdom comprised in the total

amount were valued at 10,806,092*l.*, and consisted of an endless variety of goods, of which the following are the chief articles:—

Apparel and haberdashery, ...	—	£173,782
Coal, ...	539,059 tons.	216,566
Copper, wrought and unwrought, ...	34,373 cwts.	149,785
Cotton-yarn, ...	10,943,058 lbs.	1,104,680
Cotton manufactures, ...	36,426,127 yards	918,140
Hardware, cutlery, ...	48,091 cwts.	259,860
Iron manufactures, ...	62,845 "	430,497
Linen yarn, ...	6,425,651 lbs.	483,346
" manufactures, ...	9,268,587 yards	357,800
Machinery, ...	—	267,107
Silk manufactures, ...	—	153,941
Woolen yarn, ...	20,010,597 lbs.	2,968,822
Woolen manufactures, ...	26,559,424 yards	1,520,578

The foreign and colonial produce and manufactures imported from England were valued at 6,326,625*l.*, a few of the more prominent articles being as follows:—

Coffee, ...	2,392,802 lbs.	£89,838
Cotton, ...	419,102 cwts.	3,844,526
Hides, ...	107,192 "	358,434
Indigo, ...	10,159 "	285,383
Silk, raw, ...	104,313 lbs.	106,052
Tea, ...	1,922,266 "	150,177
Wool, sheeps', ...	2,196,140 "	150,601

Among the manufacturing establishments within the Hamburg territory, sugar refineries, breweries, and distilleries take the lead. There are also cotton mills and a number of manufactories of cement, chemicals and dye-stuffs, machinery, hats, soap, walking-sticks, &c., also copper-smelting works, printing offices, and other smaller branches of industry. Beef and pork are cured largely for exportation; and the fabrication of imitation wine, chiefly port, sherry, and champagne, for the London market, continues to be carried on very extensively.

An important change took effect in 1865 in the system under which trades are allowed to be exercised within the republic of Hamburg. The guilds, to which all tradesmen and artisans were personally required to belong, and exclusive privileges formerly enjoyed by certain trading corporations, were abolished; and all trades, or industrial occupations, may now be freely exercised, not only by Hamburg citizens, but by foreigners, not subjects of the republic, who shall have obtained from the police permission to reside, and upon payment of moderate fees. Some exceptions are made in the case of advocates, medical men, brokers, &c., who are still governed by special regulations. The Jews have been declared entitled from the same date to equal rights of citizenship, and on equal conditions, with the Christian inhabitants of the republic.

These important alterations can hardly fail in the course of a few years to augment the population of the city and its suburbs in a much higher ratio than that in which it has hitherto increased. How far it may be found possible to repress the growth of pauperism, as the result of these new measures, remains to be seen. It is thought that great vigilance will be required on the part of the police authorities to prevent the settlement within the republic of mendicants and others having no visible means of subsistence.

Hamburg communicates with Lübeck by a canal

and railway, and with Berlin, Brunswick, Altona, Keil, Hanover, &c., by railway.

(Wappan's *Handbuch der Geogr. und Statist.*; *Almanach de Gotha*, 1866; *Statesman's Year-book*, 1866; and *Consular reports from Hamburg*.)

HAMELN. [CALEMBERG.]

HAMILCAR, BARCAS, the leader of the popular party at Carthage, was appointed in the eighteenth year of the first Punic War (B.C. 247) to the command of the Carthaginian forces. He ravaged with his fleet the coasts of the Bruttii and the Epizephyrian Locrians, and afterwards seized upon a strong fortress in Sicily, between Eryx and Panormus. In this place he maintained himself for some years. He frequently ravaged the southern coasts of Italy as far as Cumæ, and defeated the Roman troops in Sicily. The Romans at length fitted out a fleet to cut off all communication between Hamilcar and Carthage; the Carthaginian fleet sent to his assistance was defeated by the Roman consul, Lutatius Catulus (B.C. 241), and the Carthaginians sued for peace, which was granted by the Romans; and Hamilcar led his troops to Lilybæum, whence they were conveyed to Africa. But a new danger awaited Carthage. The Carthaginian treasury was exhausted; and it was proposed to the troops that they should relinquish a part of the pay which was due to them. The soldiers rejected the proposal, and proceeded to enforce their demands. Being joined by many of the native tribes of Africa, they defeated Hanno, the Carthaginian general sent against them, and brought Carthage to the brink of ruin. Hamilcar, being appointed to the command, succeeded in subduing them after the war had lasted above three years.

Hamilcar was sent into Spain (B.C. 238), where he remained nearly nine years, during which time he extended the dominion of Carthage over the southern and eastern parts of that country. He fell in a battle against the natives, B.C. 229.

Hamilcar was succeeded in his command in Spain by his son-in-law Hasdrubal, who must not be confounded with Hasdrubal, the brother of Hannibal. He carried on the conquests of Hamilcar, and reduced almost the whole of the country south of the Ibrus (Ebro), which river was fixed by a treaty between the Carthaginians and the Romans, B.C. 226, as the frontier of the Carthaginian dominions. Hasdrubal was murdered in his tent by a Gaul, B.C. 221. (Polybius, b. i. ii.; Appian; Nepos.)

HAMILTON, a city of Upper Canada, at the west end of Lake Ontario, 38 miles by rail from Toronto. It is one of the most prosperous and beautiful cities of the colony, mainly owing to its situation on Burlington Bay, and on the Grand Trunk and United States Railway. It is the station for steamers from Montreal, and is the seat of extensive commerce. Population in 1863, 20,000. In 1841 the number was only about 3500, and in 1851, 10,312. The principal manufacturing establishments are locomotive works, foundries, and car works. The town is in the very centre of the finest grain-producing country in America.

HAMILTON. [LANARKSHIRE.]

HAMILTON, A. [GRAMMONT.]

HAMILTON, GAVIN, descended from a noble family of Scotland, spent the greater part of his life

at Rome. Though not perhaps gifted with eminent genius for invention as an artist, yet a liberal education and refined taste enabled him at least to equal his most distinguished contemporaries. This is manifest in several subjects which he painted from the 'Iliad.' He made excavations in many parts of the Roman territory, especially at Tivoli, in Hadrian's villa. In the Museo Clementino, the statues, busts, and bas-reliefs contributed by him form the most important portion, next to the treasures of the Belvedere; and many great collections in Russia, Germany, and England are indebted to him for their chief ornaments. The 'Townley Gallery,' published under the superintendence of the Society for the Diffusion of Useful Knowledge, contains a list of the marbles procured by him for the collection of Mr. Townley. Neither the date of his birth nor death is certainly known; he died, however, between 1790 and 1800.

HAMILTON, SIR WILLIAM, Bart., Ph.D., and Professor of Logic in the University of Edinburgh, was born in Glasgow in 1788. He was for some time a student of the university of that city, and afterwards went to Oxford, where he obtained the first-class honours. In 1813 he was called to the bar; but his studies were more directed to literature and philosophy than law; and in 1821 he was appointed professor of universal history in the University of Edinburgh. In 1836 he obtained the chair of logic and metaphysics; and under his powerful ægis those subjects assumed an importance which, from the days of Dugald Stewart, Scotland may be said to have lost. While pursuing the inductive methods of Reid and Stewart, he enunciated the philosophy of the Absolute as one great step made in advance of his predecessors of the Scottish school of metaphysics. In 1852 Sir William published a volume of essays (chiefly consisting of articles previously published in the *Edinburgh Review*), entitled 'Discussions in Philosophy, Literature, Education, and University Reform.' In 1854 he brought out the first volume of the collected works of Dugald Stewart, to which he had devoted many years' close attention; but death arrested his career before its completion. He died in 1856. 'By the death of Sir William Hamilton, Scotland has lost one of the most illustrious of her sons. His attainments in general erudition were of the highest order; at once so varied and minute as rarely to be equalled, and in these times certainly unsurpassed. His writings and academic teaching have inaugurated a new era in the history of Scottish speculation.'

HAMILTON, SIR WILLIAM, a well-known diplomatist and lover of art, was born in Scotland in 1730. He began life, he says, 'with an ancient name and 1000*l.*,' but removed the discrepancy between his name and his fortunes by marrying in 1755 a lady of very large property. It is said that he was foster-brother to George III., which may account for his appointment in 1764 to be English ambassador at Naples, whence he was not recalled till 1800. He was made a Knight of the Bath in 1771, and a privy-councillor in 1791. He died, much impoverished, in England, April 6, 1803.

His great work, the 'Campi Phlegrei,' Naples, 1776-77, 2 vols. folio, is a noble monument of his researches into volcanic phenomena. Ten papers by

him, upon matters observed during his abode in Italy, are printed in the 'Phil. Trans.' for the years 1767 to 1795 inclusive. His other works are, 'Observations on Mount Vesuvius, Mount Etna,' &c., London, 1772; and 'Lettera sul Monte Vulture,' Naples, 1780.

HAMILTON, WILLIAM, of Scottish descent, but probably born in London, studied at a very early age under Zucchi, the painter of ornaments, at Rome. After his return he soon obtained general employment. He was engaged in all the public works, such as the Shakspeare Gallery, Macklin's Bible, &c. He excelled in ornament, to which he gave propriety, richness, and a classic appearance. He died in 1801, at the age of fifty.

HAMILTON, ELIZABETH, born at Belfast in Ireland, but probably of Scottish parentage, filled the office of governess to the daughters of a Scottish nobleman, for the eldest of whom her 'Letters on the Formation of the Religious and Moral Principle' were written. She died July 25, 1816.

The following are her chief works:—'Letters of a Hindoo Rajah,' 1796; 'Modern Philosophers,' 1800; 'Letters on the Elementary Principles of Education,' 1801–2; 'Life of Agrippina,' 1804; 'Letters on the Formation of the Religious and Moral Principle,' 1806; 'Cottagers of Glenburnie,' 1808; 'Exercises in Religious Knowledge,' 1809; 'Popular Essays,' 1813. Of these the 'Letters on Education' is the most sterling and important.

HAMILTON, DAVID, a Scottish architect, to whom Glasgow is indebted for its chief modern edifice (the Exchange) and some other buildings, was born in that city, May 11, 1768. Of his professional education and earlier studies little is known.

Hamilton entered into the competition for the New Houses of Parliament, on which occasion one of the four 500*l.* premiums was awarded to him for his designs. He died at Glasgow, December 5, 1843, in his seventy-sixth year.

HAMITES, a genus of cephalopodous Mollusca. It includes only fossil species, and is yet incompletely understood. According to the original views of Mr. Sowerby, only those chambered shells belong to *Hamites* which have the form of a hook or siphon bent in one plane with parallel but unequal limbs, and sinuous septa. But the specimens having these characters appear always imperfect; and when Professor Phillips found in Yorkshire many fossils, in other respects perfectly resembling *Hamites* described by Mr. Sowerby, rolled in a plane spiral, the volutions in some species touching, in others free, and in a few terminating in a straight elongation (like spirula), he extended the use of the term.

Hamites of the typical forms occur at Folkestone, Hamsey, and other situations in the gault, greensand, and other cretaceous beds. Crioceratites and Tropæum belong chiefly to the same groups of rocks in England, France, Switzerland, &c.

HAMMER POWER. For many purposes hammers are required of greater weight than a man can wield, and a great variety of steam and power hammers have come into use. As illustrations of the power-hammer we may mention Froming's forge-hammer, which is applicable to heavy castings, and also to the hammering of edge-tools, files, and knives. It may be set to work either by hand, water, or steam

power. There is a driving shaft which, when once made to rotate by any source of power, effects all the rest, through the medium of a heavy hammer-head, guide-rod, cones, and a vertical spring. The rapidity and the force of the blows can be varied. Cotton's air tilt-hammer, worked by any source of power through the intervention of a shaft, fly-wheel, fast and loose pulleys, and cones, is provided with an air cylinder to regulate the force and rapidity of the blow; there is a piston-rod in the cylinder, with a piston at the top and the hammer at the bottom, and the admission of air into the cylinder is so regulated as to give complete command over the action of the hammer. There are many other kinds, but all inferior to the steam hammer specially so called.

[STEAM HAMMER.]

HAMMERFEST. [NORWAY.]

HAMMERSMITH. [MIDDLESEX.]

HAMMOCK. In various parts of South America it is the custom of the natives to fasten the two ends of a piece of coarse cloth, or net, to the branches of trees, into which they then climb and lie suspended at their ease. This is called a *hamac*. Maritime nations have adopted the custom for the sailors' beds on shipboard. A sailor's hammock is a piece of linen-cloth, or canvas, about six feet long and three wide, with cords attached to each end, and hung on hooks under the deck. They are placed in rows about two feet apart, and are taken down every morning and stowed away. Each hammock contains a mattress and blankets, and forms the most comfortable form of bed during a voyage.

HAMMOND, HENRY, a learned divine of the Church of England, was born at Chertsey, in Surrey, August 18, 1605. Having been educated at Eton and Magdalen College, Oxford, of which he became fellow, he was presented to the rectory of Penshurst in Kent in 1633, ten years after which he was appointed archdeacon of Chichester. He was appointed canon of Christ Church and public orator in 1645, and attended Charles I. as his chaplain from the time when he fell into the hands of the army until the end of 1647. He then returned to Oxford, and was chosen sub-dean of Christ Church, from which situation he was expelled, in March, 1648, by the parliamentary visitors, and placed for some time in confinement. He died, after long suffering from a complication of disorders, April 25, 1660. Of his numerous works, chiefly controversial, the following are some of the most remarkable: 'Practical Catechism,' 1644; 'Humble Address to the Right Hon. the Lord Fairfax and his Council of War,' 1649, concerning the impending trial of Charles I.; 'Paraphrase and Annotations on the New Testament,' 1653, best edition, 1702. He began a similar paraphrase of the Old Testament, but advanced no farther than the Psalms, 1659, and one chapter of Proverbs. His works were collected by his amanuensis Fulman, 4 vols. folio, 1674–84.

HAMMOND, JAMES, was the second son of Anthony Hammond, Esq., of Somersham Place, in Huntingdonshire. He was born in 1710, and educated at Westminster; he sat in Parliament for Truro, on the interest of the prince of Wales, whose equerry he was. He died in 1742.

His verses are mostly elegiac, and addressed in the rapid style of pastoral sentiment, then in fashion, to

a fictitious object whom he names Delia. He is said to have been in love with a Miss Dashwood, who refused him, and to have lost his intellect in consequence.

HAMOAZE. [PLYMOUTH.]

HAMPDEN, JOHN, the eldest son of William Hampden, of Hampden, in Buckinghamshire, and Elizabeth, daughter of Sir Henry Cromwell, and aunt of the Protector, was born in London in 1594. He was educated at a grammar-school at Thame, afterwards at Magdalen College, Oxford, and in 1613 was admitted a student in the Inner Temple. In 1619 he married Elizabeth, only daughter of Edmund Symeon.

In the first Short Parliament to which he was elected (for the borough of Grampound) Hampden took no very forward part in the business of the house. At the close of Charles I.'s second Parliament, the king required a general loan; to this Hampden resolutely refused to contribute, denying the king's right to demand it. In consequence he was imprisoned, but was afterwards, with seventy-six others, liberated by an order of council. His resistance to the imposition of ship-money (1636) induced many to follow his example. Proceedings were instituted against him. The case was argued in the Exchequer Chamber (1637) during twelve days before all the twelve judges, who, two excepted, gave a decision in favour of the Crown.

For an account of Hampden's conduct generally in the Long Parliament we must refer to Lord Nugent's 'Memorials of Hampden,' to Clarendon, Whitelock, and the general histories. At the commencement of the civil war he raised and commanded a troop, with which he joined the parliamentary army. His counsel was for vigorous and resolute attack; he considered that Essex, the parliamentary general, should have acted more on the offensive. In an engagement with Prince Rupert upon Chalgrove Field, June 18, 1643, Hampden placed himself at the head of the attack, but in the first charge received his death-wound.

HAMPSHIRE, a county of England, lying between 50° 34' and 51° 22' N. lat., and 0° 43' and 1° 54' W. long. It includes the Isle of Wight. [WIGHT, ISLE OF.] Hampshire is bounded N. by Berkshire, E. by Surrey and Sussex, S. by the English Channel, and W. by Wiltshire and Dorsetshire. The length of the mainland portion of the county from N. to S. varies from 37 to 46 miles; the breadth from 28 to 41 miles. The area of the county, including the isle, is 1625 square miles, or 1,070,216 acres. The population in 1861 was 481,815.

Surface, Geology, &c.—The coast is low towards the east, where there is a wide bay or inlet, divided by Hayling Island and Portsea Island into three parts; Chichester Harbour on the east, Langston Harbour in the middle, and Portsmouth Harbour on the west. The coast from Portsmouth Harbour to Southampton, up the Southampton Water, is mostly flat; as is also the further portion, westward, which forms Christchurch Bay.

The surface of this county is rather irregular. The South Downs enter it from Sussex on the south-east, near Petersfield, and cross it in a north-west direction into Wiltshire. The North Downs enter the county from Surrey, near Farnham, and extend

across by Odiham, Basingstoke, and Kingsclere, into Wiltshire. The Alton Hills form a connection on the east side of the county between the South and North Downs, and run from Petersfield northwards past Alton. Portsdown is an isolated eminence, extending east and west just above Portsmouth and Langston harbours; its height is about 447 feet; its length 7 miles, and its breadth 1 mile.

A large part of Hampshire is within the basin of the Southampton Water. The principal streams which drain the Southampton basin are the Avon, or Test, the Itchin, and the Hamble. One branch of the Test rises near Hurstbourne Tarrant, and another near Whitechurch; their united stream flows by Stockbridge and Romsey to Southampton. The Itchin rises in the hills around Alresford, and flows past Winchester to Southampton. The Hamble rises near Bishop's Waltham, and joins the Southampton Water some miles below Southampton. The Beaulieu River and the Boldre Water flow through the New Forest. None of these are above 35 miles long. The Wey, the Aubourne, and the Loddon flow into the Thames basin; the Rother into the Arun basin; and the Avon and Stour flow into the Wilts and Dorset basin.

The Basingstoke canal is in the N.E., and the county is intersected by the London and South-Western Railway, with several branches, and the South Coast Railway terminating at Portsmouth.

That vast district of chalk which overspreads so large a portion of Wiltshire, and of which Salisbury Plain forms a part, extends into Hampshire, and occupies a considerable part of it, constituting the North and South Downs, and Portsdown. North of the chalk the strata belong to the London basin; south, to the Isle of Wight basin; east, to the Weald strata; west, to the chalk of Wilts and the plastic clay of Dorset.

The New Forest in this county has varied in area from time to time: at present it includes 64,000 acres, and is the property of the Crown, subject to rights of common and other ancient claims. The Crown has also manorial rights over some, and the absolute property of other, plots of ground included in the former, but not in the present, bounds of the forest. Much of the oak and beech timber for the navy is grown here. Bere forest extends northward from Portsdown Hill, and its bounds comprehend about 16,000 acres, of which one-third is inclosed. Alice Holt and Woolmer Forest contain together about 15,000 acres. Alice Holt contains much valuable timber, but Woolmer Forest, except a few patches of modern plantations, is a barren moor. Besides these forests, there is a waste of about 2000 acres, called Waltham Chase, situated near Bishop's Waltham.

Climate and Agriculture.—The climate of Hampshire is generally mild, and favourable to vegetation.

The northern part of the county consists chiefly of the poor dark sand, mixed with an ochreous loam, which is well known as the Bagshot-Heath soil. It is naturally very unproductive, and till within a few years was almost entirely covered with a brown heath, on which some hardy forest sheep and a few miserable cattle were reared, and contrived to pick up a scanty living; but a good deal of heath has been brought into cultivation. South of this district the chalk prevails, better adapted for pasture than for

corn culture. In the valleys and along the lower slopes of the chalk-hills, the soil is of a tough tenacious nature, being a mixture of stiff clay with chalk washed down the hills by the rains. This is a soil very difficult to cultivate; but it can be made to yield good crops of beans, wheat, and oats.

The land in the New Forest, and on the opposite side of the Southampton Water, is mostly of a light nature, intermixed here and there with heavier loams and clays. It requires careful drainage to make it fertile. The country generally may be said to possess poor soils.

Hampshire, although it is not equal to some eastern and northern counties for agricultural improvements, is not far behind them; and there are some farms as well managed as any in England. The farm-buildings and the agricultural implements have greatly improved of late years.

There are no breeds of cattle, horses, or sheep peculiar to Hampshire, unless we consider the small New Forest ponies in that light. The cows are of various breeds. The oxen are chiefly Sussex and Devon. The horses used in husbandry are mostly bred in other counties. The sheep are the common small forest breed, or heath sheep; the Dorset and Leicester sheep, in the richer meadows; and the South-Down, on the chalky hills. The native hogs, which live on the acorns and beech-mast of the New Forest, although the flavour of their flesh may be good, are coarse, raw-boned, flat-sided animals, and are now seldom met with. The improved breeds produced by crosses of the Berkshire, the Suffolk, Essex, and Chinese pigs, are those from which the Hampshire bacon is usually prepared. The excellence of this bacon is mainly due to the care with which the curing is effected. Hops are cultivated on the eastern border of the county, near Farnham; and large quantities of cider are made.

Manufactures and Trade.—The manufactures of Hampshire, except those connected with the dock-yard and shipping establishments at Portsmouth, are of little importance. Emsworth, on the border of Sussex, has extensive oyster beds; and Aldershot, on the borders of Surrey, is famous for its military camp, capable of accommodating 20,000 troops. Trade centres chiefly at Southampton and Portsmouth.

Divisions and Towns.—Hampshire is divided into fourteen divisions, comprehending thirty-nine hundreds. It is included in the diocese of Winchester and province of Canterbury. It is in the western circuit. The assizes are held at Winchester. For parliamentary purposes the county is divided into North Hampshire and South Hampshire, each of which returns two members to Parliament, and the Isle of Wight, which returns one; besides which Winchester, Andover, Lymington, Portsmouth, Southampton, and Newport, return two members each; and Christchurch and Petersfield one member each; total, 19 members. Registered electors (1864), Northern Division, 4116; Southern Division, 5424.

The following are the principal towns, with the population of each in 1861:—

Aldershot. [ALDERSHOT.]

Alresford, a market-town, is situated on the river Itchin, 8 miles W.N.W. from Winchester. It was formerly a more important place than it is at present. Population of the parish, 1546.

Alton, a market-town, 18 miles N.W. from Winchester. There are two well-known breweries in the town, and extensive hop plantations in the neighbourhood. The population is 3769.

Andover, a municipal and parliamentary borough, 58 miles from London by the South-Western Railway. The town contains a church, a union workhouse, two almshouses, and meeting-houses for dissenters. The town-hall is a handsome stone building, with a Grecian front. The chief business of the town consists in malting, and in the manufacture of silk and iron. The municipal borough is governed by four aldermen, and twelve councillors. The parliamentary borough returns two members. The population is 5221. Registered electors, 224.

Basing is 2 miles N.E. of Basingstoke, with a population of 1193. In the civil wars of Charles I. the castle was defended for two years against the parliamentary forces, by the fifth marquis of Winchester. It was finally stormed by Cromwell, October 14, 1645, and after yielding rich plunder to the besiegers, was burnt to the ground.

Basingstoke, a municipal borough, is 48 miles from London by the South-Western Railway. It has a considerable trade from its standing at the junction of five important roads. The church is a spacious and handsome building. There are a free school and three charity schools in the town. The malting and corn trades constitute the principal business of the place. Population, 4654. Near Basingstoke is a tract of 108 acres, on which every householder has a right of pasture.

Bishop's Waltham, a market-town, is 9 miles S.S.E. from Winchester. The principal trade of the place is in leather; and there is also some business in malting. There is an endowed free school, and several minor charities. Population, 2267.

Christchurch, a parliamentary borough, is 25 miles S. from Salisbury, and 100 miles from London by the railway. It contains a free grammar-school, a national and Lancastrian schools, and several endowed charities. The rivers Stour and Avon flow into Christchurch Bay. The borough sends one member to Parliament; population, 9368. Population of the parish, 7042. Registered electors, 413. The phenomenon of a double tide every twelve hours occurs in Christchurch Bay. The town has manufactures of watch springs and hosiery, and a salmon fishery.

Fareham is 10 miles N.W. from Portsmouth. Some small vessels are built here, and cordage, sack-ing, and coarse pottery are made. A considerable trade in corn and coal is carried on. Population of the parish, 6197.

Fordingbridge is situated on the N.W. bank of the Avon, 10 miles S. from Salisbury. There are some manufactures of sail-cloth and bed-ticking. Population, 2925.

Gosport is a fortified sea-port town, in the parish of Alverstoke, and separated from Portsmouth by the mouth of the harbour, across which a floating bridge connects the two towns. It is the terminus of a branch of the London and South-Western Railway, 66 miles from London. The inhabitants within the lighting district of Gosport numbered 7789 at the census of 1861. Most of these are engaged in the Government navy works, or in retail trade and

the supply of shipping. The ramparts form a section of the fortified barrier, inclosing Portsmouth, Portsea, and Gosport. There are extensive barracks, the Royal Clarence Victualling Yard, a powder magazine, iron foundries, and a county house of correction. Outside of the town on the south is Haslar hospital, an infirmary for seamen. The place is governed by the county magistrates, and is a polling town for the southern division of the county of Hants.

The population of the parish of Alverstoke, with Gosport, is 22,653.

Havant is situated near the head of Langston Harbour, 7 miles N.E. from Portsmouth. It has little trade. Some of the inhabitants are engaged in fishing and fowling. Population, 2470.

Kingsclere is a small town of mean appearance, 8 miles W.N.W. from Basingstoke. There is some trade in malt carried on. Population of the parish, which includes several tithings, 2774.

Lymington is a parliamentary borough, situated in the New Forest, of which it is regarded as a kind of capital, and where the Forest courts are held. Population, 4098. Population of the parliamentary borough, which returns two members, 5179. The number of registered electors in 1864 was 328. The town is situate on a steep declivity, has many houses for the accommodation of sea-bathers, a church subordinate to the parish of Boldre, a town-hall, theatre, baths, and custom-house, shipbuilding yards, and salt-works. The harbour admits vessels of 600 tons, but has little trade. Steamers ply to Portsmouth and the Isle of Wight.

Odiham is 7 miles W. from Basingstoke. The church is a large ancient brick building. Population, 2833. The town has remains of a royal palace and park, and the ruins of a castle in which David I., king of Scotland, was confined for eleven years, after his capture at Neville's Cross.

Portsmouth. [PORTSMOUTH.]

Ringwood is an ancient town, situated in the New Forest, on the eastern bank of the Avon, 16 miles S.W. from Romsey. Population, 3751.

Romsey is situated on the eastern bank of the Test, 8 miles N.N.W. of Southampton, with which it is connected by a branch of the London and South-Western Railway. It is a municipal borough, governed by four aldermen and twelve councillors. The church is ancient, and formerly belonged to a Benedictine nunnery. It is very large, lofty, and massive, and affords a fine example of Norman architecture. Population of the parish, 5848; of the municipal borough, 2116. Broadlands, the country seat of the venerated Lord Palmerston, is in the vicinity of Romsey. The town is the head of a poor-law union, and is a polling place for the county.

Southampton. [SOUTHAMPTON.]

Stockbridge is on the eastern bank of the Test, 9 miles W.N.W. from Winchester. It formerly returned two members to Parliament, but was disfranchised by the Reform Act. It is a small place, with a population of 935.

Whitchurch is 8 miles E.N.E. from Andover, on the north-west bank of the river Test. It formerly returned two members to Parliament, but was disfranchised by the Reform Act. It is an irregularly built place. Population, 1962.

Winchester. [WINCHESTER.]

History and Antiquities.—Before the Roman invasion, the county was inhabited by three tribes; the Regni (*Ρηγνοι*, Ptol.), who occupied the coast as well as the counties of Sussex and Surrey; the Belgæ (*Βελγαι*, Ptol.), who inhabited the middle portion, and extended into a district of Wiltshire; and the Atrebatæ, or Atrebatii (*Ατρεβατιοι*, Ptol.), who occupied, it is probable, the northern part, on the confines of Berkshire. This part of the island was reduced by the Romans under Vespasian. Winchester was the Roman station *Venta*. There are also remains of Roman stations at Silchester, a village on the border of the county, north of Basingstoke; and at Broughton, not far from Stockbridge. The county appears to have been the scene of contest in the Saxon invasion. Hampshire was included in the kingdom of Wessex, and *Venta* (called Wintanceaster by the Saxons) became the seat of government, and, upon the predominance of the West Saxon kings over the other Saxon potentates, became the metropolis of England. Hampshire was the scene of continual contests during the invasion of the Danes, who ravaged the Isle of Wight in the reign of Ethelred II. In the New Forest occurred several disasters to the family of William the Conqueror. His son Richard lost his life here, by what Camden describes as a 'pestilential blast;' his grandson Henry, son of Robert, was entangled among some branches and killed while hunting; and his successor William was shot there in 1100.

HAMPSHIRE, NEW. [NEW HAMPSHIRE.]

HAMPSTEAD. [MIDDLESEX.]

HAMPTON COURT CONFERENCE. [CONFERENCE.]

HAMPTON COURT PALACE is in the parish of Hampton, and county of Middlesex, fifteen miles from the city of London. It has been the favourite residence of many sovereigns, and is still one of the finest of the royal palaces in England. The river Thames flows under its walls. The original building was erected by Cardinal Wolsey, and many sumptuous entertainments were here given by him. Henry VIII. enlarged it, and stocked the park with deer. Here Edward VI. was born, and his mother, Queen Jane Seymour, died, in 1537. Elizabeth held grand Christmas festivals in 1572 and 1593. Charles I. was imprisoned in this palace, and Cromwell, Charles II., and James II., made it their occasional residence. William III. and his queen also abode here, and in great measure rebuilt it, and laid out the extensive gardens in their present style. Hampton Court Palace consists of three principal quadrangles, with some smaller courts, the eastern and southern fronts having been erected by Sir Christopher Wren. The picture-gallery comprises Lely's Beauties of the Court of Charles II., valuable specimens of Holbein, Kneller, West, Rembrandt, and numerous other celebrated painters—in all, more than 1100 pictures. Many of the ceilings and walls were painted by Verrio. The gardens, the wilderness, and maze, are a great attraction to visitors, as also is the celebrated vine, said to be the largest in Europe, which bears on an average 2500 bunches of grapes annually. These are specially set apart for Her Majesty's table. The palace is now divided into suites of apartments, which are occupied by persons of rank, who have

been reduced in circumstances. [See ARCHITECTURE, Plate 10.]

HAMSTER (*Cricetus*, Cuv.), a genus of burrowing Rodents, thus characterized by its founder. The Hamsters have nearly the same dentition as the rats, but the tail is short and hairy. On each side of their mouth are extensive sacs or cheek-pouches, which they fill with grain in order to transport it to their deep subterranean retreats. Nocturnal. Hibernates during the depth of winter. Example, the common Hamster (*Cricetus vulgaris*).

Description.—Reddish brown above; black below, with three great whitish spots on the sides. Feet white; a white spot on the throat, and another on the breast. Length about 9 inches; tail 3. Males bigger than females. Weight of some males from 12 to 16 ounces; weight of females seldom exceeding from 4 to 6.

Hamster (*Cricetus vulgaris*).

Varieties.—Variations in colour are not uncommon. There is one variety entirely black. Pennant figures one which is entirely black, with the exception of the edge of the ear, the muzzle, the under-jaw, and feet.

Localities.—All the north of Europe and Asia (Lesson), Austria, Silesia, and many parts of Germany, Poland, and the Ukraine; all the southern and temperate parts of Russia and Siberia; and even about the river Yenesei, but not farther to the east. In the Tartarian deserts, in sandy soil; they dislike moist places. Swarming in Gotha (Pennant).

Food, Habits, Reproduction.—The common Hamsters are no friends to the farmer. The quantity of grain which they consume is very great, nor does the destruction stop with mere satiety of appetite. The animal never forgets its hoard, and fills its two cheek-pouches till they seem to be bursting with the booty. In summer they feed upon various kinds of herbage; but they are also carnivorous, attacking and devouring rats, mice, birds, reptiles, &c., and even the weaker individuals of their own species. Their voice is a short growl or bark, but when irritated they utter a yelling cry. Their dwellings are under the earth; their mode of forming them, and the purposes to which they apply them, have been thus described:—They first form an entrance, burrowing down obliquely. At the end of this passage one perpendicular hole is sunk by the male; the female sinks several. At the end of these they excavate various vaults, some as lodges for themselves and young, some as storehouses for their food. Every young one is said to have its separate apartment, and each sort of grain its different vault. The 'living apartments,' as they may be called, are lined with

straw or grass. The vaults are said to be of different depths, according to the age of the constructor; a young Hamster, it is stated, makes them scarcely a foot deep, but an old one sinks to the depth of four or five, and the whole 'curtilage,' so to speak, is sometimes eight or ten feet in diameter. From the mode of proceeding in their work, the reader will be prepared for the statement that the male and female live in separate apartments; and indeed it appears that, excepting at the short season of courtship, they have very little or no intercourse. Pennant gives them a very unamiable character. 'The whole race,' writes that zoologist, 'is so malevolent as to constantly reject all society with one another. If it happens that two males meet in search of a female, a battle ensues; the female makes a short attachment to the conqueror, after which the connection ceases. She brings forth two or three times in a year, and produces from sixteen to eighteen at a birth: their growth is very quick, and at about the age of three weeks the old one forces them out of the burrows to take care of themselves. She shows little affection for them; for, if any one digs into the hole, she attempts to save herself by burrowing deeper into the earth, and totally neglects the safety of her brood; on the contrary, if she is attacked in the season of courtship, she defends the male with the utmost fury.'

Siberia produces several small species of Hamster, which have been described by Pallas.

HANAPER OFFICE, one of the offices belonging to the Court of Chancery. Writs relating to the business of the subject, and their returns, were originally kept in a hamper, *in hanaperio*; and the others, relating to matters wherein the Crown was immediately or mediately concerned, were preserved in a little sack or bag, *in parva baga*; whence the distinction of the Hanaper Office and Petty Bag Office, both of which belong to the Common-Law Court in Chancery.

HANAU-MÜNZENBERG. [HESSE-CASSEL.]

HAND. [SKELETON.]

HAND-GLASS is a name given by gardeners to a portable glazed cover which they place over certain plants for one of two purposes: either to screen them from the effects of cold and wet without depriving them of much light, or to maintain around them an atmosphere of uniform humidity. Bell-glasses differ from hand-glasses in no respect with regard to the purpose they are intended to serve, but are blown from a single piece of glass instead of being composed of many pieces fastened together. Glasses of this description are principally used to assist cuttings of plants in the process of striking root, or newly-planted individuals in establishing themselves in the soil.

HAND-TREE. [CHEIROSTEMON.]

HANDEL, GEORG FRIEDRICH, was born at Halle in Saxony, February 24, 1685 (new style). His father, a physician, destined him for the profession of the civil law, but the child's passion for music frustrated this plan, and led to his being placed under Friedrich Zachau, organist of the cathedral of Halle. He advanced rapidly under this judicious teacher. In his fourteenth year he went to Berlin, where he stayed some time. In 1703, when about nineteen, he went to Hamburg, and shortly afterwards became director of

the Opéra, which involved him in a duel, happily of no serious result, with a jealous rival named Mattheson. He was soon employed to set a drama entitled 'Almeria,' the success of which was remarkable. Next year he produced 'Florinda,' and 'Nerone' in the year following, both of which were as favourably received as his former work. He now found himself possessed of the means of visiting Italy. At Florence he was welcomed in the most flattering manner by the grand-duke, and there, in 1709, produced the opera of 'Rodrigo.' He then proceeded to Venice, and brought out his 'Agrippina,' in which horns and other wind instruments were first used in Italy as accompaniments to the voice. Handel went next to Rome, where he produced 'Il Trionfo del Tempo,' the text of which was written for him by Cardinal Pamfili, and a sacred opera, a kind of mystery, 'La Resurrezione.'

After visiting Naples, Handel returned to Germany in 1710, and accepted the office of maestro di capella to the elector of Hanover, afterwards George I. Having obtained the elector's permission, he came to England, where he composed his opera of 'Rinaldi,' his 'Te Deum,' and 'Jubilate,' his 'Water Music,' his operas of 'Amadis,' 'Teseo,' and 'Il Pastor Fido,' his 'Acis and Galatea,' 'Esther,' and other minor pieces—all before 1720. When the elector became king of England, Handel received numerous testimonials of royal favour.

The busiest but not the most fortunate period of Handel's life now arrived. The English nobility formed a project for converting the Italian theatre into an Academy of Music, and engaged him as manager, with a condition that he should supply a certain number of operas. His first opera was 'Radamisto,' the success of which was unparalleled. But Bononcini and Ariosti, two rival composers, raised a great feud against him, to calm which it was proposed that an opera in three acts should be produced, and that each of the contending composers should set one act. The drama chosen was 'Muzio Scevola,' and Handel's portion was declared the best. Handel, now master of the field, produced about fifteen new operas; but his managerial troubles were so great, that he retired from the theatre in 1726 with the loss of 10,000*l.*, and a constitution much damaged by incessant labour and constant turmoil. He then made an attempt to give operas at Covent Garden Theatre, but this proved equally mortifying and unprofitable. He next commenced giving spiritual concerts, or oratorios, at first with very little success, owing to the exertions of a clique or cabal against him. His 'Messiah' was produced in 1741, and 'Samson' in 1742; and from this time the undoubted excellence of his compositions bore down all opposition. The 'Messiah' was, during a long period, performed annually at the Foundling Hospital, and alone added 10,300*l.* to the funds of that institution. He continued his oratorios to nearly the last day of his life, deriving considerable pecuniary advantage from them.

Late in life Handel was afflicted with blindness. He died April 13, 1759. He was buried in Poet's Corner, Westminster Abbey, where a monument by Roubiliac is erected to his memory. In 1784 a great festival, the 'Commemoration of Handel' (being the centenary of his birthday), was held in the abbey,

when nearly 13,000*l.* were received for five days' performances.

Grand musical festivals, at which Handel's compositions alone were performed, were held in 1785, 1786, 1787, 1791, and 1834. In June, 1857, the first 'Great Handel Festival' was held at the Crystal Palace, when the 'Messiah,' 'Judas Maccabæus,' and 'Israel in Egypt' were performed by 2000 vocalists and 386 instrumentalists, under the supervision of the Sacred Harmonic Society. A large organ was erected specially for the occasion. A Commemoration Festival took place in 1859, with an increased number of performers, and an improved orchestra, which attracted 81,319 visitors during four days. This success led to the establishment of a Triennial Handel Festival to be held in the same place, and on the same plan, as that of 1859. The first was held in June, 1862; and the second in June, 1865, on a scale unequalled in this or any other country. At the latter the performers numbered 4000, including the principal vocalists of the day, conducted by Mr. Costa. Nearly 60,000 persons visited the Crystal Palace during the three days of the Festival and the Rehearsal which preceded it.

Handel was great in every style. In sacred music, especially of the choral kind, he not only throws at an immeasurable distance all who preceded and followed him, but reaches that sublimity which, it is now almost universally admitted, the art is so capable of attaining. The various choral societies of London are, year by year, making Handel's Oratorios more extensively known than at any former period. His works are gradually gaining favour on the Continent and in America.

In the Queen's library are the original MSS. of nearly all Handel's works, filling eighty-two large folio volumes. These include 32 Italian operas, 23 oratorios, 8 volumes of anthems, 4 of cantatas, 3 of Te Deums, and a Jubilate, together with concertos, sonatas, &c. Not in the royal collection are 11 operas, harpsichord lessons, fugues, organ concertos, water-music, &c., &c. Of the oratorios 'Deborah' was first performed in 1733; 'Israel in Egypt' in 1738; 'Saul' in 1740; 'Messiah' in 1741; 'Samson' in 1742; 'Judas Maccabæus' in 1746; 'Joshua' in 1747; 'Solomon' in 1749; and 'Jephthah' in 1751.

HANDBASTING. [BETROTHMENT.]

HANDS, IMPOSITION OF, a ceremony employed in many ancient and modern religious ceremonies, symbolical of the conferring of certain spiritual gifts. The laying on of hands is mentioned in the earliest portions of scripture: the priests laid their hands on the heads of the animals offered in sacrifice; Joshua was consecrated to his sacred office by Moses laying his hands upon his head; and Jesus Christ adopted the same rite when blessing little children. The apostles ordained ministers to their churches by the same ceremony. The early fathers, when speaking of the rite of confirmation, term it 'Imposition of hands.' The usage still remains in the Roman Catholic, Anglican, and Lutheran churches, in the ordination of ministers and confirmation, and in the former ceremony it is retained by the Presbyterians.

HANSEL, is the first act of anything. The word is used popularly to signify a first transaction in trade, the money taken for the first sale, the first

instalment paid on a debt, or the first business done on any day or week. The first Monday in the year is called *Handsel-Monday*, and a gift made on that day, a *handsel*. The word is more commonly used in Scotland than in any other part of the United Kingdom.

HANDWRITING IN LAW. [EVIDENCE.]

HANG-CHEW, a large city of China, situated on the river Yang-tze-kiang, and near the basin of the grand canal. It is the capital of the province of Tche-kiang, and one of the five first-class cities of the empire. It is extremely populous, and the number of inhabitants is supposed to equal the population of Pekin. Not less than 60,000 persons are said to be employed in the manufacture of silk.

HANGING, the principal mode of execution in the United Kingdom since the year 1240. It is only in the cases of treason and murder that capital punishment is now carried out, though in Scotland the crime of rape is also liable. Hanging is considered the most humane way of executing a sentence of death, as it is as nearly instantaneous as possible. In all cases it is done in public; but of late efforts have been made either to abolish capital punishment altogether, or at least to have it carried out privately. In the army and navy, a prisoner under sentence of death is usually shot, but sometimes hanged, which is considered a more disgraceful mode of execution. In Austria, criminals convicted of capital offences are executed as in England, Ireland, Scotland, and the British colonies. In France, convicts are decapitated by the *GUILLOTINE*; in Germany, and nearly all other European states, they are beheaded; and in Spain, garroted.

HANGING GARDENS, a term commonly applied to the celebrated gardens of Babylon, which are frequently mentioned in ancient history, and fully described by Herodotus, Diodorus, and other Greek writers. So magnificent and extensive was their structure, that they have been classed among the seven wonders of the world. It is related that they occupied a square of 400 feet on every side; and the different terraces were carried upwards one above another, until the height equalled that of the walls of the city. This prodigious work was constructed by Nebuchadnezzar for the gratification of his favourite wife Amytis, who was the daughter of a Median king, and wished to have something constructed to imitate the grandeur of her native mountain woods and forests. The whole was sustained by stupendous arches; and the soil laid upon them was sufficiently deep to enable the largest trees to take root therein.

HANGO, the name of a promontory and small town on the coast of the Gulf of Finland, belonging to Russia, and notorious for the treacherous massacre, during the last war, of a party of English who had landed with a flag of truce. It has a harbour and custom-house, and is situated 20 miles E. of Ekna, in lat. 59° 56', and long. 22° 57'. Off this promontory the Swedes were defeated by the Russians in 1714.

HANKOW, one of the treaty ports of China, in lat. 30° 30' N., and long. 114° E., is situated inland, 750 miles up the Yang-tze-kiang river. It is of great extent, in reality consisting of several cities and towns, and has a population of about 400,000. The

town suffered severely from the recent civil war, but is rapidly rising into importance again, and promises to become the most extensive mart in the empire for foreign commerce. A British settlement was made on the eastern side in 1864, and there are now more than fifty foreign business firms, a foreign inspectorship of customs, and English and American consulates. It is the chief mart of the tea districts in the interior, and carries on a large trade with Shanghai; cargoes are also sent direct to England from this port. The total value of the imports and exports in 1864 was between seven and eight millions sterling. The imports comprise shirtings, opium, copper coin, cloths, and articles of foreign manufacture. Among the exports, tea figures for 2,250,000*l.*, the other articles being silk, wood-oil, safflower, tobacco, &c. The total tonnage entered inwards for 1864 was 191,127, and cleared outwards, 204,185 tons. More than half this quantity is due to American ships—the remainder being chiefly English.

HANNAN, a city of China, on the left bank of the Yang-tze-kiang, opposite to Wunchang, 180 miles W. from Nankin. It carries on an immense trade.

HANNIBAL, the son of Hamilcar Barca, was born B.C. 247. At the age of nine he accompanied his father to Spain, who, previous to his departure, made his son swear that he would never be a friend to the Romans. He was at a very early age associated with Hasdrubal, who succeeded his father in the command of the Carthaginian army in that country. On the death of Hasdrubal, B.C. 221, he obtained the undivided command of the army, and quickly conquered many of the Spanish tribes. The inhabitants of Saguntum, alarmed at his success, sent messengers to Rome to inform the Romans of their danger. A Roman embassy was accordingly sent to Hannibal, who was passing the winter at New Carthage, to announce to him that the independence of Saguntum was guaranteed by a treaty between the Carthaginians and Romans (concluded B.C. 226), and that they should consider any injury done to the Saguntines as a declaration of war against themselves. Hannibal paid no regard to this remonstrance.

In B.C. 219 Hannibal took Saguntum, and employed the winter in making preparations for the invasion of Italy, and providing for the security of Africa and Spain. He set out from New Carthage in the spring, B.C. 218, with 80,000 foot and 12,000 horse. Before crossing the Pyrenees he left Hanno to secure his recent conquests with a detachment from his own army of 11,000 men. He sent back the same number of Spanish troops to their own cities, and, with an army now reduced to 50,000 foot and 9000 horse, he advanced to the Rhone. Two Roman armies had been levied; one, commanded by the Consul P. Cornelius Scipio, was intended to oppose Hannibal in Spain, and a second, under the other consul, T. Sempronius, was designed for the invasion of Africa. The departure of Scipio was delayed by a revolt of the Boian and Insubrian Gauls, against whom the army was sent which had been intended for the invasion of Spain, under the command of one of the prætors. Scipio raised a new army, sailed to the Rhone, and anchored in the eastern mouth of the river. But Hannibal had already crossed the Rhone, and Scipio did not arrive at the place where the Carthaginians had passed the river

till three days afterwards. Upon this, he sailed back to Italy with the intention of meeting Hannibal when he should descend from the Alps. Scipio sent his brother Cnæus into Spain, with the greater part of the troops, to oppose Hasdrubal.

Hannibal continued his march up the Rhone till he came to the Isère. Marching along that river, he crossed the Alps (probably by the Little St. Bernard), descended into the valley of the Dora Baltea, and followed the course of the river till he arrived in the territories of the Insubrian Gauls. The passage of Hannibal across the Alps has been a matter of much dispute.

Hannibal completed his march from New Carthage to Italy in five months, during which he lost a great number of men, especially in his passage over the Alps. His army was reduced to 12,000 Africans, 8000 Spaniards, and 6000 cavalry, when he arrived in the territories of the Insubrian Gauls. His first battle was with P. Cornelius Scipio on the right bank of the river Ticinus (Tesino). The Romans were defeated, and Scipio, retreating along the left bank of the Po, crossed the river, and encamped near Placentia. He afterwards entrenched himself strongly on the right bank of the Trebia, where he waited for the arrival of the army under the Consul T. Sempronius, who had been recalled from Africa. After the union of the two armies Sempronius determined, against the advice of Scipio, to risk another battle. The Romans were entirely defeated, and the troops which survived took refuge in the fortified cities. In consequence of these victories, the whole of Cisalpine Gaul (the northern part of Italy) fell into the hands of Hannibal; and the Gauls of North Italy now eagerly assisted him with men and supplies.

In the following year (B.C. 217) the Romans raised two new armies; one was posted at Arretium, under the Consul Flaminius, and the other at Ariminum under the Consul Servilius. In Hannibal's progress through the swamps of the basin of the river Arno, his army suffered much, and he lost the sight of one eye. He marched past Arretium, ravaging the country as he went, with the view of drawing out Flaminius to a battle. Flaminius hastily followed Hannibal, and, being attacked in the basin of the Lake Trasimene, was completely defeated by the Carthaginians, who were posted on the mountains which encircled the valley.

To conciliate the Italians, Hannibal dismissed without ransom all the prisoners whom he took in the battle; and, to give them an opportunity of joining his army, he marched slowly along the eastern side of the peninsula, through Umbria and Picenum, into Apulia; but he did not meet with that co-operation which he appears to have expected.

After the defeat of Flaminius, Q. Fabius Maximus was appointed dictator, and a defensive system of warfare was adopted by the Romans till the end of the year. In the following year, B.C. 216, the Romans raised an army of 80,000 foot and 6000 horse, which was commanded by the Consuls L. Æmilius Paulus and C. Terentius Varro. The Carthaginian army now amounted to 40,000 foot and 10,000 horse. The armies were encamped in the neighbourhood of Cannæ, in Apulia. In the battle which was fought near this place the Romans were defeated with dreadful carnage, and with a loss

which, as stated by Polybius, is quite incredible. The Consul L. Æmilius, and the two consuls of the former year, Servilius and Atilius, were also among the slain. Hannibal lost only 4000 Gauls, 1500 Africans and Spaniards, and 200 horse.

This victory placed the whole of Lower Italy in the power of Hannibal. Capua and most of the cities of Campania espoused his cause, but the majority of the Italians continued firm to Rome. The defensive system was now strictly adopted by the Romans, and Hannibal was unable to make any active exertions for the further conquest of Italy till he received a reinforcement of troops. Capua was retaken by the Romans, B.C. 211. Hannibal was therefore obliged to depend upon the Carthaginians for help, and Hasdrubal was ordered to march from Spain to his assistance.

Cnæus Scipio, who had been left in Spain to oppose Hasdrubal, was joined by P. Cornelius Scipio, and the war was carried on with various success for many years, till the Roman army was entirely defeated by Hasdrubal, B.C. 212. Both the Scipios fell in the battle. Hasdrubal was preparing to join his brother, but was prevented by the arrival of young P. Cornelius Scipio in Spain, B.C. 210, who quickly recovered what the Romans had lost. It was not till B.C. 207, when the Carthaginians had lost almost all their dominions in Spain, that Hasdrubal set out to join his brother in Italy. He crossed the Alps and arrived at Placentia before the Romans knew that he had entered Italy. But, before he could effect a junction with Hannibal, he was attacked by the Consuls C. Claudius Nero and M. Livius, on the banks of the Metaurus, in Umbria, his army was cut to pieces, and he himself fell in the battle. This misfortune obliged Hannibal to act on the defensive, and from this time till his departure from Italy, B.C. 203, he was confined to the country of the Bruttii; but by his superior military skill he maintained his army without any assistance from home.

After effecting the conquest of Spain, Scipio passed over into Africa (B.C. 204). With the assistance of Massinissa, a Numidian prince, he gained two victories over the Carthaginians, who recalled their great commander from Italy to defend his native state. Hannibal landed at Leptis, and advanced near Zama, five days' journey from Carthage towards the west. Here he was entirely defeated by Scipio, B.C. 202; 20,000 Carthaginians fell in the battle, and an equal number were taken prisoners. The Carthaginians sued for peace; and thus ended the second Punic War, B.C. 201.

After the conclusion of the war Hannibal vigorously applied himself to correct the abuses which existed in the Carthaginian government; but he thus incurred the enmity of many powerful men, who represented to the Romans that he was endeavouring to persuade his countrymen to join Antiochus, king of Syria, in a war against them. A Roman embassy was sent to Carthage to demand the punishment of Hannibal, but he escaped and sailed to Tyre. From Tyre he went to Ephesus to join Antiochus, B.C. 196, and contributed to fix him in his determination to make war against the Romans. But the king only employed him in subordinate command, and he had no opportunity for the exertion of his great military

talents. At the conclusion of this war Hannibal went to Prusias, king of Bithynia; and when a Roman embassy was sent to demand him of Prusias, Hannibal poisoned himself at Nicomedia, in Bithynia, B.C. 183, in the sixty-fifth year of his age.

The personal character of Hannibal is only known to us from the events of his public life, and even these have not been commemorated by any historian of his own country; but we cannot read the history of his campaigns, of which we have here presented a mere outline, even in the narrative of his enemies, without admiring his great abilities and courage.

HANNO'S PERIPLUS is a small Greek treatise, entitled 'The Periplus (i.e., voyage) of Hanno, king (i.e., commander) of the Carthaginians, round the parts of Libya beyond the Pillars of Hercules, which he posted up in the temple of Kronos.' The treatise which we possess appears to be a translation of the Carthaginian document preserved in the temple of Kronos. The time at which this voyage was performed is uncertain; Pliny (*N. H.*, ii. 67) places it in the flourishing period of Carthaginian history.

The object of the expedition is stated at the commencement of the Periplus: 'It was decreed by the Carthaginians that Hanno should sail beyond the Pillars of Hercules, and found Liby-Phœnician cities. He sailed accordingly with 60 ships of 50 oars each, and a body of men and women to the number of 30,000, and provisions and other necessities.' The first city to be founded was Thumiatierion, near the Pillars of Hercules, probably in the neighbourhood of Marmara. The most southern was Kerne. From Kerne the voyage was one of discovery; and after advancing as far south as Sierra Leone or Sherbro, according to Rennell, he was obliged to return through want of provisions.

HANOVER, THE KINGDOM OF, is situated between 51° 20' and 53° 51' N. lat., and 6° 51' and 11° 51' E. long. It is bounded on the N.W. by the German Ocean, N. by the Elbe (which separates it from the territories of Hamburg, Denmark, and Mecklenburg), E. and S.E. by Prussia and Brunswick, S.W. by Hesse Cassel, Lippe, and Prussia; and W. by Holland. The area is 14,845 square miles. The Germans write the name *Hannover*.

Divisions.—The kingdom of Hanover is divided into six provinces, called Landdrostei, and one Mining District (Berghauptmannschaft), their area and population being as follows:—

Landdrostei.	Area in sq. miles.	Pop. in 1861.	Chief Towns.
Hanover, . .	2,263	368,973	Hanover.
Hildesheim, .	1,750	366,766	Hildesheim.
Lüneburg, . .	4,488	367,669	Lüneburg.
Stade, . . .	2,528	296,626	Stade.
Osnabrück, .	2,418	262,316	Osnabrück.
Aurich, . . .	1,158	192,329	Aurich.
Mining District,	240	33,391	Clausthal.
Total, . . .	14,845	1,888,070	

Of the above population 943,581 were males, and 944,489 females. In twenty-one towns—the largest, Hanover, with 71,170 inhabitants; the smallest,

Münden, with 4432—there lived 507,156 persons, while the country was inhabited by 1,603,124. Through emigration, particularly to the United States, the country loses on the average between four and five thousand persons annually.

The nobility possess large privileges as regards the right of holding property, and civil and criminal jurisdiction. Hanover was one of the last states of Germany—the last, except Mecklenburg—in which serfdom and legal torture were abolished. The jurisdiction of the nobility on their own estates was done away with, to a great extent, in 1831 and 1848, but remnants of it still exist. The feudal service of the agricultural population was abrogated in 1831, on the condition that the value of such service be paid to the owner of the land at the rate of twenty-five years' income. It being impossible, in many cases, for the labouring people to raise the necessary capital, the redemption has not been accomplished of more than one-half in the course of thirty years.

Surface and Productions.—The southern provinces are mountainous, but from the cities of Hildesheim, Hanover, and Osnabrück, to the sea-coast, the whole country is one vast plain, with only occasional and not considerable elevations. The mountains abound in mineral wealth, and are covered with forests of red pine and fir, with some oaks and other timber. A broad sandy tract crosses the country from east to west between the mountains and the sea. The coasts are under the level of the sea, from the encroachments of which they are protected by dykes. The principal rivers are the Elbe, the Weser, and the Ems, which receive in their course numerous secondary streams, as the Aller, Leine, Ilmenau, and Lûhe, and empty themselves into the German Ocean. There are only two large lakes; the Steinhudermeer and the Dümmersee. The rivers and lakes abound in fish. In East Friesland is the subterraneous Lake Jordan, the surface of which is so thickly overgrown with vegetation that waggons can pass over it.

Agriculture, the chief source of subsistence to the inhabitants, is much favoured by the facilities for exportation when the harvest is abundant, as well as by the transit trade, and the consumption of the neighbouring maritime towns. In the marsh-land the breeding of cattle is more followed than agriculture. The country produces barley and oats, potatoes, rye, and vegetables; tobacco, hops, chicory, and hemp. The horses of East Friesland, which are celebrated, are bred for exportation to the number of 20,000 annually, and there is a government stud at Celle. The sheep are of improved breeds, and geese are extensively reared in the polders. Bees yield valuable produce in Meppen, Lüneburg, and Verden. Timber is abundant, and considerable quantities are exported.

Mining is the most important branch of industry; the chief products are those of the Harz, including iron, copper, lead, litharge, salt, turf, coal, alum, marble, and granite. The *Lower Harz* consists of detached districts on the northern and western declivities of the Harz, lying in the territory of Hanover and Brunswick, and belonging to both in common, Hanover having four-sevenths, and Brunswick three-sevenths of the revenue.

The following summary shows the comparative extent and value of the mining and metallurgic

industry of Hanover during the three years 1862, 1861, and 1860.

As regards the number of mines, foundries, salt-works, &c., there were in 1862, 246 works, employing 9751 hands; in 1861, 244 works, employing 9810 hands; in 1860, 251 works, employing 9240 hands. The total produce of these works amounted in 1862 to 13,272,846 cwts., valued at 5,094,364 dollars; in 1861 to 12,685,590 cwts., valued at 5,059,407 dollars; in 1860 to 11,208,416 cwts., valued at 4,798,168 dollars.

This summary does not include the results of the working of those mines and foundries which are owned conjointly with Brunswick. These latter produced, in 1862, 463,109 cwts., valued at 859,310 dollars; in 1861, 419,542 cwts., valued at 719,528 dollars; in 1860, 384,253 cwts., valued at 659,596 dollars.

There are several mineral springs, some of which have establishments of baths. The principal manufactures are linen, hemp, woollen and cotton fabrics, paper, soap, leather, and hats. The value of linen produce in 1861 was 98,310 dollars. Brewing and the manufacture of metals are important branches of industry.

The country is traversed by excellent roads, and railways connect the capital with Hamburg in the north, Brunswick in the east, and Hildesheim in the south. There are also several excellent canals. The railways and the telegraph lines belong exclusively to the state.

Commerce.—Although advantageously situated on the North Sea, and traversed by navigable rivers, the commerce of Hanover is not extensive, and it is conducted mostly by the towns of Bremen and Hamburg. The principal exports are linens, yarns, agricultural and mineral produce. The imports comprise manufactured goods, colonial produce, wine, and spirits. Emden and Harburg are the chief ports in Hanover; and Münden, at the junction of the Werra and the Fulda, has an active trade with the interior of Germany.

The mercantile navy of Hanover consists at present of 869 sea-going vessels, with an aggregate tonnage of 105,250 tons. The great majority of these, however, are vessels under 200 tons, only twelve being above 500 tons, and the largest of them measuring 900 tons. In 1862 there entered the different ports of the kingdom 3682 vessels, measuring 327,876 tons, and 3700 vessels, measuring 329,390 tons, cleared. Of the former, 2191 with 137,684 tons were Hanoverian, and 407 with 81,102 tons British. The trade with Great Britain engrosses nearly three-fourths of the foreign trade of Hamburg.

The value of the exports from Hanover to the United Kingdom, in 1863, was 189,643*l.*, or only one-half of the amount in 1860. The chief articles were bran, butter, caoutchouc manufactures, oats, beans, lead, oil seed-cake, paper, and sheep's wool. The imports reached 1,583,608*l.*, only one-third being the produce of Great Britain. Cotton amounted to more than one-third of the whole, the figures being 65,655 cwts., value, 590,375*l.* The other goods comprised coffee, value, 171,387*l.*; herrings, 84,181*l.*; steam engines, 61,333*l.*; iron manufactures, 59,169*l.*; linen yarn, 46,037*l.*; cotton yarn, 43,707*l.*; cocoa-nut oil, 39,242*l.*; coal, 30,196*l.*; and agricultural imple-

ments, 8613*l.* Hanover joined the German Zollverein in 1854.

Constitution and Government.—The present constitution of Hanover is embodied in the 'Landesverfassung's Gesetz' of July 31, 1840, with modifications introduced April 10, September 5, and October 26, 1848; August 1, 1855; September 7, 1856; and March 24, 1857. According to these fundamental laws, the crown is hereditary in the male line of the house of Brunswick-Lüneburg, the sovereign coming of age at eighteen. The whole legislative and executive power is vested in the king, and the representatives of the people can only give advice to the crown, or afford co-operation. These consultative and co-operative functions are vested in two bodies, an Upper and a Lower Chamber. The former consists of the princes of the royal house; the heads of five families of the upper nobility of the kingdom; the hereditary court marshal; four members nominated by the king; thirty-three deputies of the largest landed proprietors; ten deputies of chapters and colleges; ten deputies of commercial bodies; and four deputies of inns of court. One-half of the elected members of the Upper House quit their seats every three years, to be replaced by deputies nominated in new elections. The Lower House consists of two members nominated by the king, who must be ministers; of thirty-eight deputies of towns, and forty-four of country districts. The members are elected only for the term of one session; which, however, by prorogation, may extend over several years. Consultative functions are assigned, besides, to seven provincial diets, which meet every three years, and in them the ultra-conservative element is very largely represented.

The executive power is entirely and unreservedly in the hands of the sovereign, acting through responsible ministers. For facilities of administration, the ministry is divided into seven departments, the limits between which, however, are not kept up with strictness. These departments are:—Royal House of Finance and Commerce; Interior; Foreign Affairs; Justice; War; Public Education and Ecclesiastical Affairs; and Finance and Commerce.

Revenue and Expenditure.—The annual expenditure of Hanover is about 3,000,000*l.*; the revenue is somewhat less than that sum.

The public debt of Hanover has been increasing for many years, chiefly through the establishment of a network of state railways. In 1862 it amounted to—

Old debt, . . .	15,721,760	thalers, or	£2,358,264
Railway debt, . . .	30,623,075	"	4,593,460
Total, . . .	46,344,835	"	£6,951,724

Army.—The army of the kingdom is formed partly by conscription and partly by enlistment, the former supplying any insufficiency of the latter mode of raising soldiers. All citizens above twenty are liable to be drawn for conscription; but, as a rule, only a very small per centage are called up for active service in the infantry; a great portion of these troops, and nearly the whole of the cavalry and artillery, being formed of volunteers. The cavalry, especially, is a branch of service much sought after by the sons of peasants and small farmers, on account of the advantages connected therewith. The privates in

these regiments, as soon as the short term of drill and first practice is passed, are sent home on furlough, being allowed to take their uniforms and their horses. They must keep their horses partly at their own expense; but they may use them in agricultural and other labour, taking due care of the health of the animals under their charge. The term of service is seven years in the infantry, and ten years in the cavalry; but about three-fourths of this period may be spent on furlough, interrupted only by a short annual practice of arms.

On July 1, 1862, the army consisted of eight regiments of infantry, numbering 17,904 men, with 2640 troops of reserve; three brigades of cavalry, numbering 2742, with 504 reserve; three battalions of artillery, numbering 2671; two companies of engineers, 257; staff, 40. Total, 23,614 men, with 3144 troops of reserve.

The quota contributed to the German Confederation is 15,230 men. The principal fortresses are those of Stade, Harburg, and Fort-William in the harbour of Bremen.

Church and Education.—The great majority of the inhabitants of Hanover are members of the Lutheran Church. The census of 1861 showed 1,555,448 Lutherans; 97,018 members of the Reformed Church, or Calvinists; 221,576 Roman Catholics; 1943 Christians of other sects, chiefly Mennonites and Moravians; and 12,085 Jews. The administration of the Lutheran Church is under consistories, at Hanover, Stade, Otterndorf, Osnabrück, and Aurich; while the ecclesiastical government of the Calvinists is under the Church-council, or Kirchenrath of Aurich, with sub-committees at Neustadt and Nordhorn. The Roman Catholics have two bishops, at Hildesheim and Osnabrück, the former residing mostly at Rome. Like other countries of Northern Germany, Hanover is well provided with educational institutions. The most celebrated is the University at Göttingen; there are also seventeen high and thirteen lower gymnasia, five normal and twenty-one polytechnic schools, a military academy at Hanover, schools for the blind, deaf, and dumb, and about 3600 free parish schools, both Protestant and Catholic. There are also good mining and forest schools in different parts of the kingdom.

The poor are supported in workhouses, partly by the proceeds of their own labour, and partly by voluntary contributions.

The administration of the law is presided over by a special ministry. Criminal cases are tried before sworn juries. Rather more than 11 per cent. of the children born annually in the kingdom are illegitimate. In many parts of the kingdom marriage is subject to great restriction, and requires the sanction of the authorities.

History.—In the remotest times of which we have any record, the countries between the Elbe and the Weser were inhabited by small independent tribes of hunters and herdsmen. When Charlemagne first introduced the Christian religion, the country was in the power of the Saxons. Otto the Great gave, in 970, the investiture of the duchy of Saxony to Hermann Billung, a wealthy lord in Lüneburg; and his descendants, by acquiring also the principalities of Brunswick and Göttingen, laid a foundation for the larger electorate. But numerous petty broils occurred, and many little republics rose, several of which became

considerable cities. The Hanseatic League found great favour here, and of the eighty-five towns composing that celebrated confederation, thirteen were in the present kingdom of Hanover. The subsequent history of Hanover presents very little of interest, until, by the death of Queen Anne, the elector succeeded to the British throne. In consequence of this event, the electors of Hanover continued to be kings of Great Britain, till, on the death of William IV., the crown of Great Britain devolved on Queen Victoria, and the succession to the throne of Hanover being limited to the male line, the two countries were separated, and the duke of Cumberland, eldest surviving brother of King William, ascended the throne of Hanover, by the name of Ernest Augustus. Hanover was for the most part prosperous during the eighteenth century; but it suffered many diversities of fortune during the wars consequent on the French revolution, and was frequently in the hands of the French. After the battle of Leipzig in 1813, the whole electorate was restored to the lawful king, who assumed in 1815 the title of King of Hanover, that of elector having in fact ceased by the dissolution of the German empire.

In 1816 the duke of Cambridge was appointed governor-general of Hanover, and in 1819 a new constitution was granted, and two representative chambers associated with the provincial states. In 1833 another constitution was drawn up by the ministry and the states, which received the signature of William IV.; but at his death the duke of Cumberland abrogated it, and restored that of 1819. He was, however, obliged to sanction numerous liberal measures and reforms in 1848. He died in 1851, and was succeeded by his son, George V.

In consequence of a family treaty, dating back to the seventeenth century, ratified by the German Diet, and renewed between the houses of Hanover and Brunswick on March 3, 1863, it is settled that the crown of Hanover, in the event of the extinction of the male line, shall fall to the dual house of Brunswick, and *vice versa*. The present duke of Brunswick having no male heirs, it is probable that this treaty will have to be executed before long, in favour of the royal family of Hanover.

The question of the income of the kings of Hanover has never been satisfactorily settled. Since the death of King William IV. of Great Britain, and the accession of Ernest Augustus, duke of Cumberland, to the throne of Hanover, the states and the sovereign have been in conflict on this subject. The constitution of 1833 settled a civil list of 500,000 thalers, or 75,000*l.*, upon the king; but Ernest Augustus declared this sum to be wholly insufficient, and his demands for the possession of the state domains not being acceded to, he overthrew the constitution chiefly on this account. From 1841 to 1848 the royal family enjoyed the whole produce of the crown property; but in the last-named year the king was compelled to give up this source of income, and to accept the grant of the civil list of 500,000 thalers as sole income. In 1855, however, the constitution was once more overthrown, and by a royal decree part of the state property was assigned to the king's use; besides the interest of a sum of 600,000*l.*, invested by the Hanoverian government in English stocks in the years 1784 and 1790, and that of a so-called 'Schattul-

lenkapital' of 2,400,000 thalers, formed of the accumulated excess of state income over expenditure during a period of forty years. At present the income of the sovereigns of Hanover, as far as it is known, amounts to about 850,000 thalers, or 125,000*l*. (Kloden's *Erdkunde*, 1861; Milner's *Gallery of Geography*, 1864; *Statesman's Year Book*, 1866; *Consular Reports*, &c.)

HANOVER, the capital of the kingdom, lies in 50° 22' N. lat., and 9° 44' E. long. It is situated in an agreeable and well cultivated plain on the river Leine, which is navigable from the city to its junction with the Weser. The city consists of three parts, the Old Town, the Ægidian New Town, and the New Town on the left bank of the river. In the first the streets are for the most part crooked and narrow, and the houses old-fashioned and irregular; but the two other parts are handsomely and regularly built. The most interesting public buildings are the palace, the theatre, one of the largest in Germany, the mint, the arsenal, the royal mews, the town-hall, with a good library of 40,000 volumes, the royal library, with the archives, both situated on the esplanade, the museum, and fine gallery of paintings. Hanover has also four Lutheran, three Calvinistic, one Roman Catholic church, and a synagogue. Among the charitable institutions are the Orphan Asylum, infirmaries, hospitals, and poor-houses. For the purposes of education there is a collegiate school for the sons of noblemen, called the Georgianum, a lyceum, a female school of industry, many elementary schools, and a seminary for schoolmasters. In the neighbourhood are the royal country palace of Montbrillant, the gardens formerly belonging to Count Walmoden and now to the crown, with fine collections of works of art, and the royal palace of Herrenhausen. Hanover was founded in the eleventh century. Its walls, with five gates, and broad ditches, were partly levelled in 1780, and laid out in streets, and the remainder converted into a handsome esplanade. The population in 1861 was 53,089; with suburbs, 71,170.

Hanover was the first city in Germany that was lighted with gas (in 1826). The chief manufactures are gold and silver articles, oil-cloth, bronze and plated goods, starch, and chicory. It was the birth-place of the elder Herschel, and the scene of the deaths of Leibnitz and Zimmerman. It is connected by railway with Cologne, Bremen, Brunswick, and the chief cities of Germany.

HANSARDS' DEBATES, or reports of the parliamentary sessions, are the recognized authority for reference to anything that has been said or done in the English Parliament. They comprise a record of all the speeches made in both houses, collected from the London daily papers, and generally revised and corrected by the speakers themselves. The printing and publishing of these debates, though encouraged by the Government, is purely a private speculation carried on by the Messrs. Hansard. The work is issued at a fixed price, computed and guaranteed at the commencement of each session. The same publishers once enjoyed a monopoly of the parliamentary printing, of which they still retain a portion, such as the bills, reports, and some of the accounts.

HANSEATIC LEAGUE or HANSA, a celebrated commercial confederacy, which took its name from the ancient German word 'Hanse,' signifying an

association for mutual support. The cities of Hamburg, Lübeck, and Bremen were, in the middle ages, the depositories of the manufactures of Italy and Germany, with which they supplied the northern countries of Europe in exchange for their raw produce. The wealth which they acquired excited the envy and the rapacity of the princes and nobles; the imposition of new and the augmentation of old tolls were great impediments to trade, which was likewise rendered unsafe by numerous banditti and pirates who infested the roads and the neighbouring seas and rivers. Hamburg and Lübeck concluded an alliance in 1241 by which they engaged to maintain ships and soldiers for the purpose of protecting their commerce. The city of Brunswick joined the alliance in 1247. In course of time most of the trading towns in Europe joined this association, which included London, Rouen, Bordeaux, St. Malo, Bayonne, Marseille, Barcelona, Seville, Cadiz, Lisbon, Antwerp, Danzig, Dort, Amsterdam, Bruges, Rotterdam, Ostend, Dunkirk, Leghorn, Messina, Naples, Bergen, Novgorod, all the towns on the Baltic, the Elbe, and the Weser, Embden, Cologne, and other towns, to the number of 85. Their principal factories in foreign countries were Bruges, London, Novgorod, and Bergen. All the towns sent deputies to a congress which usually met in Lübeck. The Hanse Towns became so powerful that in 1348 they defeated the kings of Norway and Denmark, deposed Magnus, king of Sweden, and gave his crown to his nephew Albert; they equipped, in 1428, 40 ships of war and raised 12,000 troops, exclusive of seamen, in a war with Erick, king of Denmark; and in the same century they compelled Edward IV. to restore all their privileges and property in England, which he had attempted to withhold. That part of the city of London called the Steelyard was their exclusive property, and Bishop's-Gate, one of the principal entrances to London, was intrusted to them to guard. But when the roads and seas were no longer insecure, when America was discovered, and India was reached by doubling the Cape of Good Hope, the Hanseatic League gradually declined, and at the last general assembly at Lübeck, in 1630, the deputies from the several cities appeared merely to declare their secession from the League. Hamburg, Lübeck, and Bremen formed an association in 1641, and remained free republics till December, 1810, when they were incorporated with the French empire; but in 1813 they were again separated from France, and with Frankfurt-am-Main are now called the free Hanseatic Cities of the Germanic Confederation.

The imports and exports and other particulars of the Hanse Towns are noticed under HAMBURG, BREMEN, LÜBECK, and FRANKFORT.

HANTS. [HAMPSHIRE.]

HANWAY, JONAS, was born at Portsmouth in 1712, and died in 1786. He was a Russian merchant, connected with the trade into Persia. Business having led him into Persia, he published in 1753 his 'Historical Account of the British Trade over the Caspian Sea, with a Journal of Travels from London through Russia into Persia,' &c., 4 vols. 4to. He was made a commissioner of the navy. The Marine Society and the Magdalen Charity owe their establishment mainly to him: he was also one of the great promoters of Sunday-schools.

HAPSBURG. [HABSBURG.]

HAQUEBUT. [ARMS.]

HARBOUR, a port or haven for shipping, protected from the winds and waves, so as to secure a safe shelter for ships. Harbours of refuge are deep roadsteads where ships may take refuge at all times during storms, and are generally protected by **BREAKWATERS**. They sometimes contain an inner harbour for commercial purposes, as at Plymouth. [**DOCK.**] Ordinary harbours are formed in the mouths of rivers or other inlets of the sea, and are mostly tidal. In the earliest infancy of commerce, the necessity for artificial harbours caused the Phœnicians to exercise their engineering skill in the construction of two of enormous magnitude at Tyre. All the maritime nations of the Continent were long celebrated for their marine engineering, while England remained practically without a harbour till about the seventeenth century. Since that time, however, the progress has been rapid, and breakwaters and protecting piers have been erected at most of the numerous ports encircling our island. The best work on harbours—indeed, the only great one on the subject—is Sir J. Rennie's 'Theory and Construction of British and Foreign Harbours,' but much practical information on the subject may be found in Weale's 'Rudimentary Treatise on Civil Engineering.'

HARBURG. [LUNEBURG.]

HARCOURT, RIGHT HON. AND MOST REV. EDWARD, Lord Archbishop of York, was the youngest son of George, first Lord Vernon, and born at Sudbury Hall, county of Derby, in 1757. He was educated at Westminster, and afterwards at Christ Church, Oxford, where he received the degree of D.C.L. in 1786. At an early age he was instituted to the family living of Sudbury, appointed a prebendary of Gloucester, and made a canon of Christ Church. In 1791 he was consecrated Bishop of Carlisle, and translated, in 1807, to the archiepiscopal see of York, which he continued to hold for the lengthened period of forty years. The literary efforts of his lordship scarcely extended beyond the range of his sermons—a few only of which, delivered on special occasions, have appeared in print. He died in 1847, aged ninety.

HARD LABOUR, an addition made to a sentence of imprisonment when the offence deserves such punishment, and the condition of the prisoner will allow of it. Justices have the power of inflicting hard labour both for indictable offences and for those disposed of summarily, when the offence is of an aggravated character. It generally consists of working on the tread-mill, picking oakum, breaking stones, making mats, &c., and is limited to ten hours a day.

HARDICANUTE, HARDECANUTE, or HARDACANUTE, was the eldest son of Canute the Great, king of England, Denmark, and Norway, by Emma, daughter of Richard I., duke of Normandy. [**ETHELRED II.**] The death of Canute in 1035 brought forward, as claimants to the inheritance, Sweyn and Harold, his two sons by Alfgiva, daughter of the earl of Northampton; Hardicanute, his son by Emma; and Edward, the elder of the two sons of Emma by her former husband Ethelred. A civil war was prevented by an agreement that the authority of Hardicanute should be confined to the country to the south of the Thames, and that all

the rest of England should be resigned to Harold. Meanwhile Hardicanute remained in Denmark, leaving the government of his English province in the hands of his mother till the invasion of England, in 1037, by Emma's younger son Alfred, when Emma fled to the Continent, and Harold became undisputed king of all England. On the death of Harold, a deputation arrived from the English nobility, offering the crown to Hardicanute, who came over and assumed the government. His short reign affords scarcely any events requiring to be mentioned. His character appears to have been that of a good-natured debauchee. His death happened on the 8th of June, 1042, in consequence of what appears to have been a stroke of apoplexy.

HARDINGE, RIGHT HON. HENRY, LORD, Governor-General of India, a field-marshal of England, and commander-in-chief of the British forces, was a younger son of the Rev. H. Hardinge, rector of Stanhope, county Durham, and born in 1785. Few men had more experience in the tented field. He entered the army as an ensign in his fifteenth year, and through the whole of the Peninsular war was distinguished for his early gallantry. From 1809 to 1813 he was attached to the Portuguese army as deputy quarter-master-general, and was present at the battles of Busaco, Albuera, Salamanca, Vittoria, Pampeluna, the Pyrenees, Nivelle, and Orthes, and at the siege of Badajoz and Ciudad Rodrigo. He was again engaged in the campaign of Waterloo, and lost his left hand at the battle of Ligny. On the restoration of peace, our hero had the opportunity of resting on his military laurels; but at the end of eight years he was destined to shine in another sphere of action, as a politician and a statesman. In 1823 he was appointed clerk of the ordnance, and entered Parliament in 1826. During the premiership of the duke of Wellington, he was made secretary of war; and in 1830 he was appointed secretary of Ireland. When Sir Robert Peel came into power he resumed his post of secretary of war, and efficiently discharged its duties till 1844, when he was appointed to the important position of governor-general of India. There are few epochs in the eventful history of our Indian empire more momentous than the one for which the administration of Sir Henry Hardinge was distinguished. The war with the Seiks, who at one time threatened the safety of our northern territories, will be ever memorable in history. The battles of Moodkee, Aliwal, and Sobraon, in which Sir Henry took a prominent part, have immortalized the period. Throughout the whole of that campaign, the governor-general, though virtually superintending the conduct of the war, was content to act as second in command, and nobly to submit to the wishes and directions of the commander-in-chief. On the termination of this severe but important contest, Sir Henry was created Viscount Hardinge of Lahore. Parliament granted him an annuity of 3000*l.* for himself and his two next successors; and the East India Company gave him a pension, in addition, of 5000*l.* a year. On the death of the duke of Wellington in 1852, Lord Hardinge was appointed commander-in-chief; and during the same year was advanced to the rank of field-marshal, being the highest reward which can be conferred on military genius. He died in 1856.

HARDNESS (in Mineralogy). Mohs endeavoured to form a scale of hardness in minerals, according to the power of one mineral to scratch another. The following are ten degrees of the scale, the hardest being the diamond.

1. Talc, white or greenish.
2. Rock salt and uncrystallized gypsum.
3. Calcareous spar, cleavable.
4. Fluor spar, which cleaves perfectly.
5. Apatite, from Salzburg.
6. Adularia.
7. Rock crystal, transparent.
8. Topaz.
9. Corundum, from Bengal.
10. Diamond.

HARDOUIN, JOHN, commonly called *Père Hardouin*, was born at Quimper in Bretagne, in 1647. He entered the society of the Jesuits at an early age, and devoted himself to the learned languages, history, philosophy, and divinity. A large portion of his life was spent in undertaking to prove, chiefly from medals, that the greater part of those writings which are considered as ancient, both classical and of the early Christian age, were forged by monks of the thirteenth century. He excepted only the works of Cicero, Pliny's 'Natural History,' Virgil's 'Georgics,' and Horace's 'Satires and Epistles.' These he supposed to be the only genuine works of antiquity remaining, except a few inscriptions and Fasti; and that from these the monks had drawn up and published Terence's Plays, Livy's and Tacitus' Histories, Virgil's *Æneid*, Horace's Odes, &c. See his 'Chronologiæ ex Nummis Antiquis restitutæ Prolusio, de Nummis Herodiadum,' 4to., Paris, 1693. The society of Jesuits at last interfered, and Hardouin, in 1708, published the recantation of his faucies.

HARDWARE MANUFACTURES are among the chief sources of the wealth of England, the great seats of which are at Birmingham, Sheffield, Wolverhampton, Walsall, &c. The term includes the smaller articles made of any of the commoner metals, such as grates, tools, locks, keys, shovels, &c. We have no means of ascertaining the quantity manufactured for home use, but the export statistics give some idea of the extent of the trade. In 1864 the total value of hardwares and cutlery exported was 4,159,107*l.*, which was divided as follows:—Cutlery and surgical or anatomical instruments, 398,276*l.*; iron and steel manufactures, tools, &c., 514,221*l.*; and manufactures of German silver, pewter, Britannia metal, lamps, &c., 3,246,610*l.* The United States, Germany, France, Australia, India, and the colonies, were the principal markets.

HARDWICKE, PHILIP YORKE, first EARL OF, was the son of an attorney at Dover, where he was born 1st December, 1690. His father was not able to do much for his education, but the great abilities of the son enabled him to surmount all difficulties. He was a great favourite with Mr. Samuel Morland, a man of considerable learning, who kept a school at Bethnal Green, London, at which he was placed for a short time. When removed to the office of Mr. Salkeld, an eminent solicitor in London, his diligence and talents won the respect of that gentleman also. Mr. Salkeld caused him to be entered of the Middle Temple, in November, 1708. During the time he was keeping his terms, he became acquainted

with Mr. Parker, one of the sons of Lord Chief Justice Macclesfield, the consequence of which was an introduction to Lord Macclesfield, who employed him as the companion and tutor of his son. To this lucky acquaintance the rapid and extraordinary success of Mr. Yorke at the bar is mainly attributable. In May, 1715, he was called to the bar, when the support of his old benefactor Salkeld, who was in very extensive practice as a solicitor, together with the favour and patronage of Lord Macclesfield, enabled him at the very outset to acquire an extensive practice.

The elevation of Lord Macclesfield to the woolsack (1719) enabled him further to promote the interests of his favourite, and accordingly through his influence, in the same year, Yorke took his seat in the House of Commons as member for Lewes, the whole expenses of his election being defrayed by the ministry. In the same year he married Mrs. Lygon, a young widow, the daughter of Mr. Cocks, a gentleman of good estate in Worcestershire, and the niece of Lord Somers and Sir Joseph Jekyl, then master of the rolls.

In March, 1720, while upon the circuit, and within five years after his call to the bar, he was, through the influence of his patron the chancellor, appointed solicitor-general; and he justified the choice by his conduct. In 1724 he was made attorney-general. It was after this period that his patron, Lord Macclesfield, was impeached for gross corruption in office, and Sir Philip Yorke had great difficulty in procuring himself to be excused from the task of assisting the managers of the Commons in making good their charge. In 1733 he was appointed lord chief justice of the King's Bench, and created Baron Hardwicke. He presided in the King's Bench for three years and a half, during which period he added largely to his former high reputation. On the death of Lord Chancellor Talbot (1737) he was raised to the dignity of lord chancellor. It is upon his judgments as chancellor that the reputation of Lord Hardwicke is principally founded. He held the great seal during nearly twenty years, and his judgments are a lasting monument of his legal knowledge and the soundness of his understanding. His integrity was never called in question. In 1754 he was created Earl of Hardwicke and Viscount Royston. He continued to hold the great seal until the 19th of November, 1756. He died on the 6th of March, 1764. Lord Hardwicke's judgments are preserved, so far as the points decided by them, in the reports of Atkyns and Vesey, sen., and in a volume published from Lord Hardwicke's own notes, by Mr. West. Some notes of his decisions have also been made public by Mr. Lee. These volumes, however, do not give any notion of the language in which the judgments were delivered. Few specimens of his style of writing remain.

HARDYNG, JOHN, one of our old historians, was born in 1378, and at the age of twelve was admitted into the family of Sir Henry Percy, eldest son of the earl of Northumberland, and known by the name of Hotspur, with whom he fought as a volunteer at the battles of Homildon and Cokelawe. After the death of his patron, whom he accompanied in the battle of Shrewsbury, Hardyng enlisted under the banner of Sir Robert Umfravile, who was con-

nected with the Percys by affinity, and under whom in 1405 he became constable of the castle of Warkworth in Northumberland. How long he remained at Warkworth is unknown; but his knowledge of Scottish topography seems soon to have engaged him in the secret service of his country. The exact time when Hardyng was first sent to obtain restitution of the deeds of homage, which had been given up by Mortimer in the minority of Edward III., does not appear; but it must have been early in the reign of Henry V.

Several writers have considered our author as a dexterous and notable forger, who manufactured the deeds for which he sought reward. But whether this was the case, or that Hardyng, in his zeal for his country, became the tool of some more powerful person, or was imposed upon in the purchase of the deeds, cannot now be ascertained.

Actively as Hardyng was engaged in life, he seems to have been constantly employed in gathering materials for his Chronicle, the first composition of which he finished towards the latter end of the minority of Henry VI.

Hardyng appears to have received several grants and pensions as rewards for his services. The evening of his days was passed in the entire recomposition of his work, which was afterwards presented to King Edward IV. The history comes no lower than the flight of Henry VI. to Scotland. From a passage in which the queen is mentioned, it is evident that he could not have finished his work before 1465. How long he survived its completion is unknown, but he must then have been eighty-seven years of age.

HARE. [LEPORIDÆ.]

HARE-BELL. [CAMPANULA.]

HARE-LIP, a malformation in which the lip is divided in one or more places by clefts extending from its free edge towards its attachment. It has received this name from the resemblance which it bears to the divided upper lip of hares and other gnawing animals, and is one of the most common of the malformations by arrest of development. Hare-lip may be single or double, that is, there may be one or two fissures—the one may be seated in the middle line of the lip, or opposite to the union of the two incisors with the canine tooth—if there be two, they will be found in the latter situation on each side. It may be simple or complicated with fissures of the gum or palate, which, being developed in an analogous manner, may be influenced by the same cause as the lips, though being earlier united they are less rarely affected.

The cure of hare-lip is important, not only for the uncouth deformity, but because sucking is prevented in infancy, and in later life the speech is affected. It is accomplished by cutting off quite smoothly the opposite edges of the fissure in its whole length, and then bringing them together and maintaining them in accurate apposition till, like the edges of a common wound, they have firmly united.

HARE, VEN. ARCHDEACON JULIUS CHARLES, was born at Hurstmonceux, in Sussex, in 1796. He graduated as M.A. at Cambridge in 1819; was instituted to the rectory of Hurstmonceux in 1832; appointed archdeacon of Lewes in 1840; and collated to a prebend at Chichester in 1851. In 1847 he published, in conjunction with a

younger brother, a volume of miscellaneous thoughts and observations, entitled 'Guesses at Truth, by two Brothers,' which passed through various editions. His translation, however, of 'Niebuhr's History of Rome,' in 1828, more generally attracted the notice of the literary world. But he became still more distinguished by his theological and controversial writings, which extend over a period of nearly thirty years. Among others may be noticed, 'The Means of Unity' (1847); 'The Duty of the Church in Times of Trial' (1848); 'The True Remedy for the Evils of the Age' (1850); 'The Contest with Rome' (1852); besides a great number of charges and sermons at different periods. In 1848 he edited the *Essays and Tales of John Stirling*, with a Memoir of his life. The tolerant character of the biographer was well calculated to appease that *odium theologicum* which too frequently pervades an assembly of divines. He died in 1855.

HAREM, a seraglio, or place where Eastern potentates confine their women, who are prohibited from the society of others.

HARFLEUR. [SEINE-INFÉRIEURE.]

HARGREAVES, JAMES, the inventor of the carding-machine and the spinning-jenny, was an artisan at Stanhill, near Blackburn, in Lancashire, where he was born. He and his family supported themselves by weaving and spinning, carried on in his own house, according to the custom of the time and place. In 1760 he invented the carding-machine, as a substitute for the hand-cards previously used. In 1764 he contrived that kind of apparatus for spinning by machinery since known as the jenny, and made one with eight spindles, which was driven by hand. So strong was the prejudice at that time against the use of machinery in manufacturing, that it was necessary for Hargreaves to make and work his machines in secret. At length the unusually large quantities of yarn brought by his family for sale to the factory, drew attention and suspicion upon him, so that a band of workmen broke into his house, and destroyed his machinery and furniture, and he became the object of a persecution which compelled him to leave the neighbourhood. In 1768 he removed to Nottingham, whither he had been invited by a company of stocking-weavers to become the manager of a spinning mill. Soon afterwards, in conjunction with a partner named Thomas Jones, he set up a factory at Hockley for spinning yarn for the hosiers, which he carried on with moderate success till his death in April, 1778, when his share in the mill was bought by his partner, from his widow, for 400*l*.

HARICOT. [BEAN.]

HARINGTON, SIR JOHN, was born at Kelston, near Bath, in the year 1561. His mother was a natural daughter of Henry VIII., and his father held an office in the court of that king. Having been educated at Eton and at Christ's College, Cambridge, he, by means of his wit and accomplishments, gained the notice of Queen Elizabeth, and became a member of her court.

When the earl of Essex was appointed Lord Lieutenant of Ireland in 1599, Harington was made a commander of horse under Lord Southampton, in his service. When Essex shortly after made his precipitate return to England, Harington was one of the few officers whom he chose to accompany him, and he

came in for a share of the queen's indignation. She was angry also, we are told, that Essex had, in Ireland, conferred on Harington the honour of knighthood. On the accession of James I. in 1602, Harington continued in possession of royal favour. He now wrote for the private use of Prince Henry his 'Brief View of the State of the Church,' which is an account of the bishops who lived in the reigns of Elizabeth and James I. He died in 1612.

Sir John Harington, besides a translation of the 'Orlando Furioso,' wrote a satirical poem entitled the 'Metamorphosis of Ajax,' a volume of epigrams, and several occasional pieces in verse, most of which have never yet been published.

HARLEIAN COLLECTION. [BRITISH MUSEUM.]

HARLEQUIN, one of the performers in modern Christmas pantomime. The name is probably taken from the Italian *arlecchino*, or the French *arlequin*, who was the jester or satirist of the early drama. The harlequin of the present day wears a tight dress covered with spangles, and represents the most respectable part of the pantomime. The other principal characters in this kind of play are the columbine, a good dancer, and partner of harlequin: the clown, the comic fool of the entertainment; and pantaloon, the butt of the clown. It requires clever acting to sustain these parts, and many reputations have been made by them, notably that of Grimaldi, an English clown.

HARLESS, GOTTLIEB CHRISTOPH, a learned and laborious German philologist, was born at Culmbach in 1738, and died November 2, 1815. He held several academical offices in the University of Erlangen. The most important of his publications is an edition of the 'Bibliotheca Græca' of Fabricius, Hamburg, 1790-1811, in 12 vols. 4to.

HARLEY, JOHN P., a popular comedian, and for many years chairman of the Drury Lane Theatrical Fund, was born in London in 1786, and at a very early age adopted the stage as a profession. He first made his *début* in 1815 on the Metropolitan boards at the English Opera House, in the character of Marcelle, in the 'Devil's Bridge,' and Peter Fidget in 'The Boarding House.' He soon afterwards made his appearance on the boards of old Drury in the character of Lissardo, in 'The Wonder,' since which he continued to maintain a high position in public favour, as a lively and mirth-inspiring comedian. During the later period of his life he constantly played at the Princess' Theatre, where he was a deserved favourite. His last principal performance was in the laughable farce of 'Samuel in Search of a Wife.' He died, August 22, 1858, from a stroke of paralysis, with which he had been suddenly seized the previous night, while acting his favourite character of Launcelot Gobbo.

HARLEY, ROBERT, EARL OF OXFORD, was born in London in 1661, of a family of note in the county of Hereford. He entered Parliament after the Revolution as member for Tregony, and afterwards sat for Radnor, professing for some time the Whig principles of his family. After a transition period, however, he went fairly over to the Tories. In the House which met under the administration of Rochester and Godolphin, in February, 1701, Harley was elected speaker by a great majority, and

also in the next parliament. He was a third time chosen to the same office, in October, 1702, and retained it till April, 1704, when he was made secretary of state. He is believed to have been principally indebted for this promotion to the good offices of Miss Abigail Hill, who, according to the duchess of Marlborough, by Harley's management became Mrs. Masham, and in return exerted all her influence to attach the weak mind of the queen to Harley and his friends. In this state of things the Marlborough party began to seek a new support by inclining towards the Whigs. The struggle was finally decided against Harley by the public suspicion and odium to which he became exposed in consequence of the conviction of one of his clerks named Gregg, for carrying on a treasonable correspondence with France. In the beginning of February, 1708, the duke of Marlborough and Lord Godolphin intimated to the queen, that unless Harley were removed they would leave her service; on this the secretary resigned, along with Mr. St. John (afterwards Lord Bolingbroke). Harley remained out of power for about two years and a half; at the end of which time Godolphin was dismissed, and Harley was appointed chancellor of the exchequer. The duke and duchess of Marlborough, and all their connections, were completely discarded both from office and from the queen's favour. Harley was appointed lord high treasurer, created Earl of Oxford and Earl Mortimer, and invested with the order of the garter. The peace of Utrecht, concluded 5th May, 1713, is the event for which the administration of Harley is chiefly memorable. It was after this that the jealousy between the premier and Bolingbroke assumed the character of an open rivalry. Bolingbroke had now the art to gain the favourite, Lady Masham, and on the 27th day of July, 1714, the lord treasurer received his dismissal. The queen's death, three days after, put an end for ever to the political existence of both Oxford and Bolingbroke. In August, 1715, both were impeached by the House of Commons. St. John made his escape to France, but Harley was committed to the Tower, and there he lay two years, when he was brought to trial before the House of Lords; but the Commons not appearing to prosecute their impeachment, the prisoner was acquitted. After this the earl of Oxford lived in retirement till his death, May 21, 1724. Three disquisitions on financial and political subjects, said to be written by him, appear in the Somers Collection of Tracts.

HARLINGEN, a seaport in the province of Friesland, Holland, about 65 miles N.E. of Amsterdam. It is a flourishing port, has important commercial relations with England and Norway, exporting large quantities of butter and cheese, and numerous animals. It has a population of 9000, chiefly employed in commerce, refining salt, and making sail-cloth and bricks. The town is protected from the inroads of the sea by a very large dyke forty feet high.

HARLOW, GEORGE HENRY, was born in London in 1787. His father, who was a merchant, died while he was an infant. He was educated for a few years at Westminster School, but when about sixteen was placed with a Flemish landscape-painter of the name of De Cort, whom he left for Mr. Drummond, A.R.A., the portrait-painter; and he was finally placed in the studio of Sir Thomas

Lawrence (then Mr. Lawrence), with the privilege of copying pictures there, but with an especial proviso that he should receive 'no instruction of any kind.' At the expiration, however, of a year and a half, the master and pupil quarrelled.

Harlow never studied at the Royal Academy: he professed to consider study in schools and academies as so much time spent in the destruction of originality. His first picture of note was Hubert and Prince Arthur; and he painted a few other historical pieces; the most celebrated of them is the Trial of Queen Catherine, of which the principal characters were portraits, Mrs. Siddons as Queen Catherine, John Kemble as Wolsey, &c. Harlow painted many portraits, of which the best is certainly that of Fuseli.

Having obtained a considerable reputation and some means, Harlow set out, in June, 1818, upon a visit to Rome, where he attracted great notice and excited some wonderment by completing an effective copy of the Transfiguration, by Raphael, in 18 days. Canova was much pleased with it, and told Harlow that it looked like the work of 18 weeks; he exhibited one of Harlow's pictures at his house, and it procured him his election as a member of the academy of St. Luke, where it was also exhibited. Harlow wrote a most sanguine letter from Rome, November 23, 1818, full of hopes and plans for the future; but in less than ten weeks from that date he died in London on the 4th of February, 1819.

HARMATTAN, the name of a hot suffocating wind, which blows from the interior of Africa towards the Atlantic Ocean. The term is derived from the Fantees, a nation on the Gold Coast, where this terrible blast is the most prevalent. It occurs during the months of December, January, and February; and sometimes it continues with unremitting violence for six or seven days. It takes its rise in the great desert of Sahara, and passes over Senegambia and Guinea to that part of the coast of Africa, lying between Cape Verde in N. lat. 15°, to Cape Lopez in S. lat. 1°, an extent of coast line nearly 2000 miles. Extreme dryness is the property of the Harmattan; and during its continuance there is not the least appearance of moisture in the atmosphere. No dew falls; the grass withers; and all vegetation of a tender description perishes. The very furniture of the house and the panels of the doors crack and split from excessive heat and dryness. Still, with all these annoyances, the Harmattan is considered as highly conducive to health. During its influence fevers disappear, and the most malignant diseases are alleviated. The cause may be thus accounted for—the wind immediately follows the rainy and unhealthy season on the African coast, and by its excessive dryness dispels the humidity from the atmosphere, and counteracts its baleful effects on the animal system. It is thus in the physical as in the moral world—

'All partial evil, universal good.'

HARMO'DIUS. [ARISTOGITON.]

HARMONIC PROPORTION. The reciprocals of numbers which are in arithmetical proportion are themselves said to be in harmonic proportion; thus

$$\frac{1}{a}, \frac{1}{a+b}, \frac{1}{a+2b}, \&c.,$$

is a series in harmonic progression.

A line A B is said to be harmonically divided when two points, C and D, one within it and one

A	C	B	D

on its continuation, are so placed that A C is to C B as A D to D B. In this construction C D is an harmonic mean between A D and B D, or A D, C D, and B D are as the reciprocals of terms in arithmetical proportion.

HARMONICA, or **ARMONICA**, an instrument somewhat similar to that now known as musical-glasses. It was invented by Benjamin Franklin. He saw an Irishman playing airs by the friction of his finger on a row of drinking-glasses, which he tuned by putting water into each. He then mounted a number of glasses on an iron rod by means of a perforation in the bottom of each. The glasses partly fitted into each other without touching, and were tuned by grinding, and in this way three complete octaves were got into a small space. The rod was then fixed in a box, and being set in motion the tones were brought out by applying a wet finger to the surfaces of the glasses. The arrangement, however, was objectionable on account of its liability to get out of order, and none of its numerous admirers have ever succeeded in improving it. Other instruments of no merit or importance took the same name, but had very little resemblance to the original.

HARMONICS (Acoustics). By the harmonics of a musical note are meant all those other notes in which the number of vibrations per second are twice, three times, four times, or any multiple of, the number of vibrations which produce the note in question. Thus the harmonics of a note which is sounded by 200 vibrations per second are those notes which require 400, 600, 800, &c., vibrations per second. The harmonics of a note are infinite in number, theoretically speaking, and proceed by less and less intervals. And, since every note may be considered as identical with any of its octaves, every harmonic has a corresponding note in any given octave. Denoting any key-note by C, and the octave above it by C', there is no possible sound between C and C' which is not theoretically either an harmonic of C, or as near to one as we please.

But, in practice, not only is it impossible to produce any number of harmonics we please, that is, to maintain in vibration any aliquot part we please of a string or column of air, but even among the harmonics which we can produce we find a limit to the number of those distinct harmonics which deserve the name, etymologically considered. Some few of the first harmonics are melodious sounds, considered in relation to the key-note, but others are discordant, and find no place in the scale according to any system of temperament. We shall therefore, taking a given note, say C, simply mention the most important harmonics, and reduce them to their proper places between C and C'.

Let a be the number of vibrations per second which produce C; then $2a$ is well known to produce C', or the first harmonic of a note is its octave. The next has $3a$ vibrations, answering to G'; so that the twelfth, or octave of the fifth, is the second harmonic. The third has $4a$ vibrations, and answers to C'', the octave of the octave. The fourth har-

monic has $5a$ vibrations, and gives E'' , the double octave above the third, in the untempered diatonic scale. The fifth harmonic, with $6a$ vibrations, gives G'' , the octave of G' the second harmonic. In general, every harmonic whose vibrations are an even multiple of those in the key-note, is an octave to a preceding harmonic, and presents no new character. The sixth harmonic, having $7a$ vibrations, is an imperfect (being too flat) double octave to the flat seventh above the key-note, or B flat. The eighth harmonic, with $9a$ vibrations, is correctly D'' , or three octaves above the untempered major second. The tenth, with $11a$ vibrations, is a little too sharp for F''' , being $11a$ instead of $10\frac{3}{4}a$. The twelfth, with $13a$ vibrations, is a little too flat for A''' , being $13a$ instead of $13\frac{1}{2}a$.

The preceding summation is useful, as giving an account of the scale of all those musical instruments which consist of one unaltered pipe. These are the bugle, the French horn, the trumpet, and (but for its slide) the trombone; in all of which (except the last) no note can be produced except an harmonic of the fundamental note of the whole tube. Calling the fundamental note C (which, however, is not very easily sounded), the ordinary scale of these instruments is—

C C' G' C'' E'' G'' (B'' flat) C''' D''' E''' F'''
 G''' A''' ,

in which B'' flat is too flat, F''' is too sharp, and A''' too flat. A short pipe, however, will not produce many harmonics; the bugle goes no further than G'' , at least with common lips. Various contrivances have been introduced to extend and correct this scale; the keyed bugle, the use of the hand in the French horn, the pistons sometimes applied to the same instrument, and the short slide of the trumpet, to say nothing of the slide, which is the principal distinction of the trombone, will suggest themselves to all who are acquainted with musical instruments. In other instruments harmonics are much used, particularly in those of the violin class, and the flute. The performance of Paganini upon a single string, which created a great sensation among violin players, arose from extraordinary power of producing harmonics. In the flute, C''' may be attained without much practice, as an harmonic of the fundamental note of the instrument; and we have heard of players who could produce D''' and even E''' in the same way. On the long strings of a pianoforte, as the fundamental note subsides, G' , C'' , and E'' may be perceived; and we have heard, among the vaulted roofs of a cathedral, several of the harmonics of the notes sounded in chanting.
 [ACOUSTICS.]

HARMONIUM, a musical instrument which owes its origin to the invention, or rather the revival, of the *free vibrating reed*. There are many claimants to this invention, but the Chinese were undoubtedly acquainted with it long before its introduction into Europe. The harmonium is usually about three feet and a half high, and the same in breadth; it has a compass of five octaves of keys, from C to C or from F to F , the key-board being placed on the top below the lid. Under the key-board is the wind-box, inside which the different reeds are placed. The notes are produced by wind furnished by means of bellows, worked by the foot, and forced into the air-chest,

and thence into the wind-box. This latter occupies the whole width of the instrument, and is separated into two or more compartments. There is a complete row of reeds in each part, and the keys form valves closing all the cavities until pressed down, when it opens them all, and the wind rushing through makes the tongues or reeds vibrate. The free reed used in the harmonium is formed of a brass frame containing a narrow rectangular slit, at one end of which a thin elastic spring of the same metal is fixed. This tongue is a little smaller than the opening, so that when a current of air is projected against it, it yields to let it pass; but its elasticity forces it back into the opening, and its momentum carries it to an equal distance on the other side. The spring at the free end is permanently bent a very little outwards. The vibration produces a musical sound, so long as the current of air is maintained. The vibrations of the reed depend for their rapidity on the thickness of the tongue at the free end in proportion to its length. If thick at the free end and thin at the fixed, the vibrations will be comparatively slow, and the resulting note deep; if the tongue be thin at the free end and thick at the fixed, a higher note will be the result. The quality of sound is also affected by the breadth of the vibrating part of the reed and the shape of the aperture in the wind-chest covered by the valve. The sizes of the reeds differ according to pitch, from four inches to one-half inch in length. Any note may be made loud or soft by varying the pressure of the wind. Harmoniums are made of various sizes and qualities, at prices from 4L . to 50L . They are chiefly manufactured in Paris, and many of those professedly made in England are brought in pieces from France, and merely put together here. They are chiefly used as a substitute for the organ, which they resemble in tone and variety of powers. But the great drawback to the general use of these instruments is a certain reediness of tone, and especially the unmitigated volume of the sound. Many methods have been adopted to obviate these serious defects, but all seem to have been only partially successful, except that of Messrs. James Gilmour & Co., of Glasgow, who have obtained patents for improvements which completely obviate the defects referred to. In order to gain complete power of modulation, a box is placed over the reed chest, fitting closely, so that the sound is as effectively confined as if the instrument were shut into another room; in the top of this box two openings are cut, and valves or lids placed over them; these covers have arms attached to them, which being made to turn on a bridge, and projecting over the action towards the back of the instrument, the full power of the sound may be obtained by pressing down the extreme ends of these arms, and so opening the lids or covers which confine the sound. Part of Messrs. Gilmour's patent is for connecting these arms with the wind reservoir by means of an elastic cord, so that when a moderate supply of wind is used the covers remain closed; but as it expands, the elastic cords open the covers, and thus produce a most perfect swell. These arms may also be acted on by means of stops. In order to gain an improved tone and separate control over the bass and treble portions of the instrument, the reed chest and swell box are

both differently arranged; in the reed chest, instead of a continuous row of vibrators, the bass portion is placed a little towards the back of the instrument, and the treble portion a little towards the front, so as to admit of a division being run lengthwise between them by means of a partition in the swell box—in this case there are four openings cut in the cover of the box, one immediately over the reeds and one at the end farthest from the reeds, and fitted with covers so that when the cover most distant from the reeds is open, the sound having to travel, as it were, through a pipe, acquires a round organ-like quality. This arrangement has also this advantage, that either portion of the instrument may be kept subdued while the other is allowed to predominate; thus, if the covers over the treble portion only are opened, the treble will be powerful; while the bass is kept subdued the covers remaining closed.

Messrs. Gilmour & Co. have also constructed some very powerful instruments, for church use, built on quite a novel plan, which bring out the value of their patent improvements very strikingly. The reeds, instead of being all in one box, and placed, as is usual, under the keys, are divided into different boxes, no one of which contains more than two sets of reeds. These different reed chests with their swell boxes are built up one over another *above* the key board, thus giving free vent to the sound. They are generally covered with cases of a Gothic design, which, together with the organ-like tone they have, might easily be mistaken for a real pipe organ.

HARMONY (in Music), musical sounds simultaneously produced according to certain rules, forming a chord, or succession of chords. The simplest harmony, namely, the triad, or common chord [**CHORD**], is the result of the vibration of all sonorous bodies, and the foundation on which much artificial harmony is built.

In addition to the details given under **COUNTERPOINT**, the following are some of the rules of Harmony:—

1. No two perfect concords, namely, two 5ths or two 8ths, are allowed to succeed each other in the same progression, but are permitted in contrary motion, that is, when one rises and the other falls.

2. Most discords require to be *prepared*, and all must be *resolved*; i.e. the dissonant note is to be first heard as a concord, and after *percussion*, or being sounded, must pass into a concord, generally by falling a tone or semitone. But sometimes the resolution is brought about by the bass.

3. It is in the nature of sharpened intervals to rise, and of flattened ones to fall.

4. In music in four or more parts, the parts should be separated in a manner as nearly equal as possible: thus a more perfect symmetry is obtained, and a richer harmony produced. But, with a view to some particular effect, a very different distribution of the parts is occasionally made.

5. As a general rule, every composition, whatever its kind, is to commence in its key; but, as regards the termination, the rule is without exception and peremptory, though sometimes the third is changed from minor to major.

By *Harmónia* (*ἁρμονία*) the Greeks meant to express the proper relationship of one sound to another, the pleasing agreement of intervals, in a melody, and

nothing beyond; and it is a disputed question whether the Greeks were acquainted with what is now known by the name of *Counterpoint*.

HARMOTOME (*Andreeolite, Ercinite*) occurs at Strontian in Scotland, in right rhombic prismatic crystals, colour grayish red, yellowish white; sp. gr. 2.4. Its chief constituents are silica, barytes, alumina, and water.

HARO. [**CASTILLA LA VIEJA.**]

HAROLD I. was the younger of the two sons of Canute the Great, by Alfgiva. [**HARDICANUTE.**] He died in 1040.

HAROLD II., the second of the sons of Godwin, earl of Kent, makes his first appearance in political history after the death of Canute, as a supporter, in concert with Queen Emma, of the succession of Hardicanute. [**HARDICANUTE.**] On Godwin's death his earldom of Kent, which, besides that county, comprehended all Wessex and Sussex, was given to his second son, Harold, Harold's own earldom of East Anglia being transferred to Alfgar, the son of Leofric, styled earl of Leicester, the potent rival of the Godwin family. This arrangement was not submitted to by Harold: Alfgar was outlawed on a charge of treason which Harold brought against him; on which flying to Ireland he speedily returned with a force of Danes from that country, and of auxiliaries from Wales, to levy war against the king. Harold was despatched to meet the rebels; but a contest was prevented by a negotiation which restored his earldom to Alfgar. Harold meanwhile, as the king's commander-in-chief, turned to chastise the Welsh for the aid they had given to the revolt; and a series of hostilities with that people commenced, which did not finally terminate till 1063. It was about two years after this that Harold was shipwrecked on the coast of Ponthieu, where he was immediately seized by the Earl Guy, and on the demand of William, duke of Normandy, delivered over to that prince. William did not permit his prisoner to embark for England till he had compelled him to take a solemn oath that he would do everything in his power, on the decease of Edward, to promote the duke's succession to the English crown. On the death of Edward the Confessor (5th January, 1066), a report having been circulated that Edward had named Harold for his successor, he was proclaimed king, and next day solemnly crowned, a few hours after the interment of the late king.

For more than half a year Harold was left to occupy the throne. Two foreign enemies, however, at length assailed him nearly at the same time. His brother Tostig, having formed a confederacy with Harold Hardrada, king of Norway, sailed round at the head of his fleet of sixty vessels to the mouth of the Tyne, where he was joined about the beginning of September by Hardrada with a navy of three hundred sail. The invaders had made themselves masters of the entire province of York before Harold came up. On the 25th, however, he engaged them at Stamford Bridge, on the Derwent, when both Hardrada and Tostig fell, and the English king obtained a complete victory. Only three days after this the duke of Normandy landed at Bulverhithe, between Pevensey and Hastings, on the southern coast, with a mighty armament, which he had spent eight months in fitting out. Harold did not reach

the Norman camp till the 13th of October. On the morning of the following day battle was joined at a place then called Senlac (now Battle), about nine miles from Hastings. The issue of this memorable engagement was the complete defeat of the English, after Harold himself had fallen, pierced through the head by an arrow. This victory gave the crown of England to the duke of Normandy, by whose descendants it has ever since been worn.

HAROLD'S CROSS. [DUBLIN.]

HARP, among the Romans, the name of a species of framework used by the soldiers as a drawbridge when besieging the walls of a city, and so called from its resemblance to a harp.

HARP (*hearp*, Saxon), a musical instrument, which, under different forms and denominations, may be traced to the remotest ages. Martianus Capella found the harp in use among the northern tribes which overran the Roman empire in the fifth century. Jones, the Welsh bard, claims for his country the possession of a harp of twenty-six diatonic notes, so early as the beginning of the sixth century. An ancient Irish harp has been sketched by Bunting, which had in a row forty-five strings, and an additional seven in the centre, as unisons.

The Welsh triple-stringed harp of the present day extends from G an octave below the first line in the bass to G, or A in altissimo on the *right* side; and from G, the first line in the bass, to the same upper notes on the *left* side; the middle row consists of the semitones of the outward rows. Hence, if the outside rows be tuned in the diatonic scale of G, each parallel note being in perfect unison, the notes of the middle row are tuned a semitone higher.

The harp, as a generally useful instrument, may be said to date its existence from the time when pedals were added to it, by the invention of Sebastian Erard. With these it is possible to modulate into all keys, and to execute any music suited to keyed instruments. In the *single-action*, the pedals raise every string half a note; in the *double-action*, the instrument is tuned in C flat; and by fixing the pedals in the first groove the instrument is at once transposed into C natural; whereas by fixing them in the second groove it is transposed another semitone higher, into the key of C sharp. The compass of the harp thus improved is from double E below the bass to E in altissimo.

HARPAGINES (Gr. *arpages*, 'hooks'), naval implements of war used by the ancients for catching hold of the enemy's ships, and raising them up in the air, by which they were frequently sunk or destroyed.

HARPA'LIÐÆ, an extensive family of coleopterous insects of the section of *Geodephaga*, the species of which are distinguished by the tarsi of the two anterior pairs of legs being dilated in the male sex.

In these insects the tibia of the anterior pair of legs have always a deep notch on the inner side; the head is almost always short and rounded in front; the thorax is generally broader than long, somewhat convex, but slightly narrower behind than before, and nearly equal in width to the elytra. The body usually approaches more or less to a cylindrical form; the elytra are almost always rounded at the apex, and never truncated at this part. They are usually found under stones.

HARPER'S FERRY, is a town in the United States, 50 miles N.N.W. of Washington. It is in the state of Virginia, at the junction of the Shenandoah with the Potomac. It has three churches, an iron foundry, and a national armoury. It surrendered to the troops of the Confederacy, during the civil war, on the 15th September, 1862. It is celebrated as the scene of John Brown's abolition raid in 1858.

HARPIES (Gr. *arpazo*, 'to seize'), in mythological history, a kind of winged monsters, with faces like women, bodies like vultures, and hands and feet hooked, like the talons of a bird of prey. They are often mentioned by the poets under the names of Aello, Ocypete, and Celeno; and are noticed in the third Book of Virgil's 'Æneid,' as having plundered Æneas during his voyage towards Italy, and predicted many of the misfortunes which accompanied his journey.

HARPSICORD, a keyed musical instrument, in form the same as the grand pianoforte, but smaller, strung with steel and brass wires, two to each note, which were struck by *jacks*, armed with small pieces of quill, acting as plectrums, and thus made to render a brilliant but somewhat harsh sound, wholly unlike that produced by the hammers of the pianoforte. *Stops*, *swells*, and double rows of keys were occasionally employed to modify the power of the wires. The harpsichord came into use in England in the seventeenth century; but it is now entirely superseded by the PIANOFORTE.

HARPY EAGLE. [FALCONIDÆ.]

HARQUEBUSS. [ARMS.]

HARRIER, the English name for the hound employed in hunting the hare. It is similar to the foxhound, from which it differs chiefly in its smaller size, and its inability to run so fast. Its scent, however, is extremely keen, which enables it to follow all the doublings of the hare. Persons hunting with harriers are exempt from taking out a game licence.

HARRINGTON. [CUMBERLAND.]

HARRINGTON, JAMES, descended from an ancient and noble family in Rutlandshire, was born in January, 1611. At the close of his residence at the University of Oxford, during which his father had died, he set out on a course of travels; and on his return to England principally passed his time in retirement. But in 1646 he was requested by the commissioners whom Parliament had appointed to carry King Charles I. from Newcastle nearer to London to wait on his majesty. He complied with the request, and was shortly after made a groom of the bedchamber. On the king's removal from the Isle of Wight to Hurst Castle, Harrington was removed from the king's service, and on his subsequently refusing to swear that he would not assist or conceal the king's escape, he was placed under arrest, and detained until an application of General Ireton obtained him his liberty. He afterwards showed his attachment to the king by accompanying him to the scaffold.

'After the king's death,' says Mr. Toland, 'he was observed to keep much in his library, and more retired than usually, which was by his friends a long time attributed to melancholy or discontent.' He was engaged, however, in the composition of his 'Oceana.' When he had proceeded some way in its

composition, making no secret of his views on government and of his partiality towards a commonwealth, he found that he had already brought down upon himself the suspicions both of Cromwell and of the Royalists. His book was seized, while in the press, by Cromwell's order; but Harrington eventually recovered it through the intercession of Lady Claypole, Cromwell's favourite daughter.

The 'Oceana' on its appearance excited great attention. Answers were published, and those Harrington in turn answered. In 1659 Harrington published an abridgment of the 'Oceana,' under the title of the 'Art of Lawgiving;' and subsequently several tracts. He had also founded a club, called the Rota Club, at which he gave nightly discourses on the advantage of a commonwealth and of the ballot. The club was broken up after the Restoration. But the members had become marked men.

On the 28th of December, 1661, he was seized on a charge of having taken part in a conspiracy to subvert the monarchy and establish a commonwealth. Having received no answer to several petitions, he made application for a Habeas Corpus; and shortly after this had been granted he was removed without previous notice to a rock opposite Plymouth, called St. Nicholas' Island. His confinement soon produced an effect upon his health, and upon petition he was allowed to be removed to Plymouth. Shortly after he became deranged, owing, it is supposed, to a medicine recommended to him for the cure of the scurvy. Lord Bath, the governor of Plymouth, then made intercession with the king, and Harrington was released from imprisonment. On being removed to London, he rallied considerably as regards bodily health, but his mind was never again right. At his advanced age, and in this unsatisfactory state of health, he married. He died of palsy on September 11, 1677.

HARRIOT, THOMAS, an eminent mathematician and astronomer, was born at Oxford in the year 1560. He took his degree of Bachelor of Arts in 1579, and in 1584 he accompanied Sir Walter Raleigh in his expedition to Virginia, where he was employed in surveying and mapping the country, and upon his return to England in 1588 he published his 'Report of the Newfoundland of Virginia, the commodities there found to be raised,' &c. Harriot was introduced by Sir Walter Raleigh to the earl of Northumberland. This enlightened nobleman received Harriot into his house, and settled on him an annual salary of 300*l.*, which he enjoyed to the time of his death, in July, 1621. During his lifetime Harriot was known to the world merely as an eminent algebraist; but from a paper by Zach in the 'Astronomical Ephemeris' of the Royal Academy of Sciences at Berlin for the year 1788, it appears that he was equally deserving of eminence as an astronomer. Ten years after Harriot's death his algebra, entitled 'Artis Analyticæ Praxis, ad Æquationes Algebraicas nova, expedita, et generali Methodo resolvendas,' was published by his friend Walter Warner.

HARRIS, GENERAL LORD GEORGE, one of the most distinguished officers of our Anglo-Indian army, was born at Brasted in Kent, in 1746. After passing through the different grades of regimental rank, in 1799 he proceeded to India, as lieutenant-colonel of the 76th Regiment, and as secretary to

Sir W. Meadow, who had been appointed governor and commander-in-chief of Madras. Colonel Harris was actively engaged in 1790 and 1791 against Tippoo Saib; and on his return to England in 1794, he was appointed to the rank of major-general. He soon afterwards re-embarked for India, and received the appointment of commander-in-chief, under the presidency of Fort St. George. In 1798 he was chosen by the earl of Mornington to command the army against the sultan, Tippoo Saib, with a force of about 50,000 men. His skill and bravery in this important undertaking are matters of history. He eventually effected the capture of Seringapatam, and the annexation of the dominions of Tippoo to the eastern dependencies of the British crown. In acknowledgment of his distinguished services, he was in 1815 raised to the peerage, by the title of Lord Harris, of Seringapatam and Mysore in the East Indies, and of Belmont in Kent. In 1820 he was made a Grand Cross of the Bath, and in 1824 appointed governor of Dumbarton Castle. He died in 1829.

HARRIS, JOHN, D.D., born about 1667, died September 7, 1719, a voluminous writer, in the list of whose works we find numbers of sermons, treatises on algebra and fluxions, geometry, trigonometry, astronomy, and navigation. He also wrote 'Remarks on some late papers relating to the Universal Deluge and the Nat. His. of the Earth;' 'Navigantium atque Itinerantium Bibliotheca, or a complete collection of Voyages and Travels,' &c., 1705, 2 vols. folio, reprinted with additions and corrections in 1744 and 1764; 'Lexicon Technologicum, or an Universal English Dictionary of the Arts and Sciences, explaining not only the terms of Arts, but the Arts themselves,' 2 vols. folio, 1704-10 (from this, says Watt, 'have originated all the other dictionaries of arts and science and cyclopedias that have since appeared'); 'History of Kent,' 2 vols. folio, 1719. Harris was secretary and vice-president of the Royal Society, and possessed considerable church preferment, but was reduced to poverty by neglect of his affairs. He died in want, and was buried at the expense of his friends.

HARRIS, JAMES, born July 20, 1709, was the eldest son of James Harris, Esq., Salisbury, by the Lady Elizabeth Ashley Cooper, sister of Lord Shaftesbury, the author of the 'Characteristics.' He was educated at the grammar-school in his native place, and passed thence to Wadham College, Oxford. In his twenty-fifth year he lost his father, and thereby became independent in fortune. For fourteen years of his life he did little else than study the Greek and Latin authors with the greatest diligence. In 1745 he married the daughter of John Clarke, Esq., of Sandford, near Bridgewater, by whom he had five children. In 1761 he was returned M.P. for Christchurch, which seat he retained till his death. In 1762 he was appointed to the post of a lord of the Admiralty, and next year to that of a lord of the Treasury, which he held for two years, when his party went out of office. In 1774 he became secretary and comptroller to the queen. He died in 1780. The chief work of Harris is his 'Hermes, or a Philosophical Inquiry concerning Language and Universal Grammar,' a work which Lowth characterized as one of the most

beautiful pieces of analysis which had appeared since the days of Aristotle.

The real merit of this work of Harris is perhaps best expressed in the following few words from the first sentence of his sensible preface: 'The chief end proposed by the author of this treatise in making it public has been to excite his readers to curiosity and inquiry.' A careful perusal of the treatise cannot fail to make a man think more accurately.

Harris' 'Hermes' was published in 1751. Some years before, he had written three treatises, on Art, on Music, Painting, and Poetry, and on Happiness; and in 1775 he published his 'Philosophical Arrangements,' a part of a large work on the Aristotelian Logic. His last work is called 'Philological Enquiries.'

HARRIS, JAMES. [MALMESBURY.]

HARRISBURG, an important city of the United States, North America, in the county of Pennsylvania, on the Susquehanna, crossed here by a covered railway bridge, 2876 feet in length. It is situated 106 miles W.N.W. of Philadelphia, and has the usual public edifices of a large town. Population, 13,405.

HARRISON, JOHN, was born at Faulby, in Yorkshire, in 1693. Harrison early displayed an attachment to mechanical pursuits, and his attention was particularly directed to the improvement of clocks. After many failures and many minor improvements, he at length succeeded in constructing a pendulum, the excellence of which depended on the different degree in which metals are expanded or contracted by variations of temperature. In 1735 he came to London with a timepiece which he had constructed, to compete for the prizes offered by the government in 1714 in reference to the longitude. After several trials, he produced a chronometer which erred only 5.1 seconds in a voyage from England to Port Royal; this was sufficient to determine the longitude within eighteen miles; and, after twenty-two years of struggling and delays, Harrison received the prize of 20,000*l.* in 1767. Harrison introduced many and varied improvements in clocks, chronometers, and watches. He died at his house in Red Lion Square, in 1776, in his eighty-third year.

HARRISON, THOMAS, generally called 'Harrison of Chester,' although he was not a native of that city, for he was born at Wakefield in Yorkshire, in 1744. While yet little more than a mere lad, he was sent to Italy, then considered almost the only efficient school for architectural study; and during his stay at Rome, where he remained for several years, he made designs for improving and embellishing the Piazza del Popolo, which obtained for him both a gold and silver medal from Pope Ganganelli; and he was also complimented by being elected a member of the Academy of St. Luke. On his return he executed various public works at Chester, Liverpool, Manchester, Shrewsbury, and also in Scotland. Harrison died at Chester, March 29, 1829.

HARRISON, WILLIAM HENRY, President of the United States, was born in Virginia, February 9, 1773, and was educated at Hampden Sydney College, in Virginia, for the medical profession; but after the death of his father, who was governor of Virginia, he joined a force which was raised to defend the Ohio territory against the Indians; and

the next six years of his life were spent in military service. In 1797, this war having been brought to an end, he resigned his commission as lieutenant, and was appointed secretary and *ex-officio* lieutenant-governor of the north-western territory, then comprehending all the country to the north-west of the river Ohio. In 1799 he was elected a member of the territorial government. In 1801 he was appointed governor of Indiana. He greatly distinguished himself both in the war with the Indians under Tecumseh in 1811, and in that with the English in 1812 and 1813. In both these wars he held the rank of a general. In 1816 he was returned to the House of Representatives as one of the members for Ohio. In 1828 he was sent as minister to Columbia; and in 1840 he was elected president; but he died at the official residence in Washington, on the 4th of April, 1841, being the first president who had died in office.

HARROLD. [BEDFORDSHIRE.]

HARROW. [PLOUGH.]

HARROW. [MIDDLESEX.]

HARROWBY, RIGHT HON. DUDLEY RYDER, EARL OF, was born in London in 1762; and few men have occupied more important stations in the great political arena of his country. At the age of twenty-two, young Ryder represented the family borough of Tiverton in the House of Commons; and the first office conferred upon him was that of under-secretary of state for foreign affairs. Under the ministry of Pitt, in 1791, he was appointed paymaster of the forces, and vice-president of the board of trade; and in 1800 he received the treasurership of the navy. In 1804, having been called to the House of Peers on the death of his father, he was intrusted with the seals of the Foreign Office, and shortly afterwards was appointed chancellor of the Duchy of Lancaster—both of which offices he soon resigned, but still retaining his seat in the cabinet. In 1809, in consideration of his political services, he was raised to the dignity of an earl by the titles of Earl of Harrowby and Viscount Sandon. In the course of the following year his lordship published a well-written pamphlet on the necessity of augmenting the poorer church benefices, the result of which was a grant of 100,000*l.* for the relief of the poorer clergy. He also obtained the passing of an act for the better support of stipendiary curates; and it is generally considered that this 'Curates Act,' which is known by his lordship's name, has tended more than any other statute of modern times to raise the character of the church. On the formation of the Liverpool ministry, the dignified office of president of the council was conferred upon his lordship. In 1819 a committee of the Lords was formed to investigate the state of the currency, and the noble earl was placed at its head. The report which he then prepared was considered a very important document, and has often, since that period, been referred to as a work of considerable authority. It was at the mansion of his lordship, in 1820, that the assassination of the ministry, by the Cato Street gang, was to have taken place; and it was, in a great degree, owing to the prudent measures of the earl that the atrocious intention was defeated, and the conspirators brought to justice. In 1827 his lordship retired from the service of the Crown, and soon

afterwards withdrew altogether from public life. He died in 1848.

HARROWGATE. [YORKSHIRE.]

HARRY, BLIND, as he was commonly called, or *Henry the Minstrel*, lived towards the close of the fifteenth century. He was born about the year 1470, according to Wharton. The work for which Blind Harry is celebrated is a poem on the adventures of Wallace.

HARTE, WALTER, was educated at Marlborough School and Oxford. He seems to have been born about 1700, and to have graduated as M.A. in 1730. Harte published 'Poems on Several Occasions,' 1727; 'Essay on Satire,' 1730; 'Essay on Reason,' 1735, to which Pope is said to have contributed very considerably; 'Essay on Painting,' date unmentioned; 'The Amaranth,' 1767, his last work. As a poet, however, he is not distinguished from other once successful but now forgotten imitators; but he has made a valuable addition to our literature in his 'History of the Life of Gustavus Adolphus,' 2 vols. 4to., 1759; republished in 8vo., corrected and improved, in 1763. Harte left unfinished, in MS., a 'History of the Thirty Years' War.' The account of his life is soon told. He took orders, acquired reputation as a preacher, was appointed principal of St. Mary Hall, Oxford, and through the interest of Lord Chesterfield, whose son's tutor he had been, canon of Windsor. He died at Bath in 1774.

HARTFORD. [CONNECTICUT.]

HARTLEPOOL. [DURHAM.]

HARTLEY, DAVID, was born on the 30th of August, 1705, and was the son of a clergyman of Armley in Yorkshire. Having been first educated at a private school, he entered, at fifteen years of age, at Jesus College, Cambridge, and became in time a fellow of that society. Scruples which would not allow him to subscribe the Thirty-Nine Articles prevented him from afterwards entering the church, as had been originally intended; and he applied himself to the medical profession, in which he attained to considerable eminence.

He commenced the composition of the work by means of which he has become universally known, the 'Observations on Man, his Frame, his Duty, and his Expectations,' at the age of twenty-five. The fundamental idea of the work, the possibility of explaining all states of mind by association, was first suggested to him by Mr. Gay's 'Essay on the Fundamental Principle of Virtue or Morality,' prefixed to Law's translation of Archbishop King's 'Origin of Evil.' His work was published in 1748. He lived nine years after the publication.

Dr. Hartley was twice married, and had children by both marriages. He practised medicine successively at Newark, Bury St. Edmund's, in London, and at Bath, where he died on the 25th of August, 1757. He enjoyed through life the friendship of many distinguished literary men. Among these may be mentioned Bishops Law, Butler, Warburton, and Hoadley, Dr. Jortin, Young the poet, and Hooke, the author of the History of Rome.

HARTSHORN, the horn of the *Cervus Elaphus*, the common stag, which has a place in the pharmacopœia because it contains less earthy matter, and more gelatine, than other bones. It is kept in the form of shavings, of which a sufficient quantity boiled

in water yields a jelly suitable to convalescents, which may be flavoured with lemon-juice or wine, &c.; but there is no proof that it is superior to jelly made from calves' feet. It is sometimes a useful addition to milk for young children, but it possesses no alkaline properties, and the further addition of a little lime-water is often necessary to fit it for irritable stomachs.

HARTSHORN, SPIRIT OF. [AMMONIA.]

HARTZ. [GERMANY.]

HARUN-AL-RASHID. [ABBASIDES.]

HARUSPICES, a class of priests in ancient Rome, whose principal duty was to inspect the entrails of victims, and thereby foretell future events. They also interpreted various phenomena, such as lightning and earthquakes. This art, called *Haruspicina*, was derived from Etruria.

HARVARD COLLEGE, in Cambridge, Middlesex county, Massachusetts, United States, was founded in 1638, and so named in honour of the Rev. John Harvard, who gave it 700*l*. The present value of the buildings, grounds, and endowments belonging to the college is 1,613,880 dollars, and including the library and apparatus, exceeds 2,000,000 dollars. The government is vested in the president, five fellows, and a board of overseers appointed by the state legislature. The Unitarians have at present a numerical majority on the board of council, and may be said to control the institution, but do not exert any conscious denominational influence. In 1864 there were forty-four tutors, including professors of law, medicine, science, and divinity; 814 students; 152,500 volumes in the library; and the annual current expenses amounted to 130,000 dollars. The College, or University as it is sometimes termed, is a very flourishing one, and many of the most distinguished Americans have been educated in it.—(*American National Almanac*, 1866.)

HARVEST. In southern countries, where the heat and want of moisture are not too great for the growth of corn, the only care of the farmer, as to harvest, is to procure hands sufficient to reap it. The heat of the sun and air soon dry the straw and harden the grain. A spot is levelled in the field, and the corn is thrashed out immediately, either by the tread of cattle driven over it or by the flails of numerous thrashers. The corn is winnowed and stored in granaries; and the straw is reserved till winter, when it forms the chief fodder of horses and cattle. But in northern climates, where the harvest is later, and cold rains and storms are frequent in autumn, the ingenuity is often taxed to save the corn, after it has been cut, from being entirely spoiled. The reaping machines, however, now coming into pretty general use, will vastly accelerate the process of cutting, and diminish the risk from exposure of the crops to bad weather. [AGRICULTURAL IMPLEMENTS.]

It was long the custom through the whole of the north of Europe to store all the produce of the farm into barns; but the increase of the produce raised by an improved system of agriculture gave rise to the practice of stacking corn in the open air, and securing it by a covering of thatch. Formerly corn was so cut as to leave much of the straw standing on the ground; but modern farming is so conducted, that the straw is cut as near the ground

as possible. In many places it is not usual to tie up any corn into sheaves, except rye, wheat, and beans. Barley and oats are usually mown, raked into heaps, and carried into the stack or barn when dry, like hay; but this is a slovenly practice, which should not be recommended. With good tillage and proper manuring, the straw of barley and oats will be strong, and of sufficient length to require being tied up into sheaves; and much less of the grain is shaken out and lost in this way than by the usual method.

When the stack is building, the butts of the sheaves are placed outwards, and project gradually over the sides of the frame, and over one another, so as to build the stack in the form of a bowl, with a cone or pyramid over it, according as the frame is round or square; this is carefully thatched with straw, and the outer surface is cut smooth by means of shears. Various other forms of stack-building are adopted in different countries. Harvest is proverbially a joyous time, and one when hospitality is practised with more goodwill than at any other season. Harvest-home rejoicings when the last corn is carried have been observed from time immemorial; and the good old custom is again reviving on the well-conducted farms of England.

HARVEST-BUG (*Leptus autumnalis*) a species of the family *Leptidae*, or harvest-ticks, belonging to the group *Acaridae*, or mites. It lives among the grass, is exceedingly small, and causes great irritation by its bite when it gets on to the skin. In some districts it occurs in autumn almost as a plague.

HARVEST SPIDER (Lat. *Phalangium*), a genus of the *Phalangidae*, belonging to the family of the tracheal *Arachnidae*, in which the head, thorax, and abdomen are united, and the legs exceedingly long and slender. The tarsi often consist of more than fifty joints. The antennæ of the jaws are large, and furnished with a didactyle claw.

These insects are extremely voracious; and sup-

Harvest Spider.

ported on their stilt-like limbs, they stalk about among plants, in our gardens and fields, in search of insect prey. Some forms, belonging to the same family, are remarkable for the shape of their abdomens, which project into spines and angles of every description.

HARVEY, WILLIAM, was born at Folkestone, in Kent, April 1, 1578, and, after having been some years at the grammar-school of Canterbury, was admitted at Caius College, Cambridge, in the year 1593, being then in his sixteenth year. Having devoted himself to the study of logic and natural

philosophy for six years in that university, he removed to Padua, at that time a celebrated school of medicine, where he attended the lectures of Fabricius ab Aquapendente on anatomy, of Minadous on pharmacy, and of Casserius on surgery. He was admitted doctor of medicine there, and returned home at the age of twenty-four. At thirty he was elected fellow of the College of Physicians, and shortly after appointed physician to St. Bartholomew's Hospital. On the 4th of August, 1615, he was chosen by the College to deliver the Lumleian lectures on anatomy and surgery, and upon this occasion he is supposed to have first brought forward his views upon the circulation of the blood, which he afterwards more fully established, and published in 1628.

Before the time of Harvey the opinions on the circulation were numerous and inconsistent. The blood was supposed to be distributed to the various parts of the body by means of the veins, and that intended for the nutrition of the lungs by the action of the right side of the heart. According to the same doctrines the arteries were destined for the conveyance of the vital spirits, which were formed in the left side of the heart from the air and blood derived from the lungs. These vital spirits were supposed to be taken in by the arteries during their diastole, and distributed by them during their systole, whilst the vapours or fuligines, as they are called by Harvey, were returned to the lungs by the action of the left ventricle. Opinions did not agree upon the mode in which the blood found its way to the left side of the heart, for whilst some supposed that it was conveyed with the air from the lungs, others maintained that it transuded by certain imaginary pores in the septum between the ventricles. These opinions, it is evident, rested more upon imagination than any careful observation of facts. Those of Harvey, on the contrary, were drawn from the most accurate dissections of dead and living animals, and supported by arguments depending entirely upon the anatomical structure and obvious uses of the parts. The result of these observations is thus stated by him. The heart has periods of action and of rest, but in warm-blooded animals its motions are so rapid, that the different steps of them cannot be distinguished. In cold-blooded animals they are more slow, and in warm-blooded also, after the examination of its action, by opening the chest of a living animal, has been continued some time. During its action the heart is raised, and its point tilted forward so as to strike against the parietes of the chest. It contracts in every direction, but more especially on its sides; it also becomes harder, as other muscles do during their contraction. In fishes and cold-blooded animals the heart may be observed to become paler during its systole, and assume a darker colour during its diastole. If a wound be made in the ventricle, the blood is ejected from it during its contraction. From these facts Harvey concluded that the essential action of the heart is its systole, and not its diastole, as was supposed by physicians before his time, and that the result of this contraction is the expulsion of the blood into the pulmonary artery and aorta. The diastole of the arteries or pulse is synchronous with and caused by the propulsion of the blood during the systole of the

ventricle, and is a passive, and not, as was previously supposed, an active operation of the vessels. If the motions of the heart be carefully observed for some minutes, it will be seen first that the two auricles contract simultaneously, and force the blood contained in them into the ventricles; and, secondly, that the ventricles in their turn assume the same action, and propel most of the blood into the pulmonary artery and aorta, from which it is prevented from returning by the valves situated at the entrance of those vessels. He then describes the manner in which the blood passes from the right to the left side of the heart, showing how it first passes through the lungs, and passes to the left auricle and from thence to the left ventricle. In like manner he showed that the blood is propelled from the left ventricle into the arteries, and so distributed to all parts of the body. He next proceeded to give approximate calculations of the quantity of blood which passes from the veins through the heart in a given time. This he showed to be so much more than is required for the nutrition, or can be supplied to the veins by the absorption of alimentary substances, that the surplus must of necessity return through the various tissues of the body to the veins again. He then argued from the construction of the valves of the veins that the course of the blood in them must be from the smaller to the larger divisions, and thus to the heart again.

Such is a brief abstract of the principal steps in this the greatest and most original discovery in physiology, which was so directly opposed to all the previous notions of physicians that its author observed, that he feared injury to himself from the envy of some, or that he should make enemies of all. Harvey afterwards complained to one of his friends, that his practice fell off considerably after the publication of his treatise 'On the Circulation of the Blood,' and it is well known that the doctrine was not received by any physician who was more than forty years old. He subsequently published a volume entitled 'Exercitationes de Generatione,' which contains a description of the organs of generation in the common fowl, of the formation of the egg and its extrusion from the body, and of the use and nature of its various parts, as well as the changes which it undergoes during the process of incubation.

In the same treatise are also some valuable observations on the process of generation in mammalia, which were confined chiefly to the deer species, of which he was enabled to obtain numerous specimens by the liberality of Charles I., who allowed him to take them from the royal parks.

In 1623 Harvey was appointed physician extraordinary to James I., with a promise of succeeding on the first vacancy to the physicianship in ordinary, the duties of which he actually performed. He was afterwards physician to Charles I., and was in the habit of exhibiting to him and to the most enlightened persons of his court the motion of the heart and the other phenomena upon which his doctrines were founded. During the civil war he travelled with the king, and while staying for a short time in Oxford was made by him master of Merton College, and received the degree of Doctor of Medicine. He held the mastership, however, for only a few months, when Brent, who had been expelled by the king for favouring the parliamentary cause, was replaced by

that party, which had now gained the ascendancy. Soon after, his house was plundered and burned by the same party, and unfortunately several unpublished works, of which we have only notices in his other writings, were destroyed. The latter years of his life were chiefly spent at his country-house at Lambeth, or at his brother's near Richmond. In 1654 he was elected president of the College of Physicians, but in consequence of his age and infirmities he was induced to decline that honourable office. But he testified his regard for the society by presenting them with his library, and conveying over to them, during his lifetime, a farm which had been left him by his father. He died on the 3rd of June, 1657, in the eightieth year of his age, and was buried at Hempstead in Essex, where a monument was erected to his memory. The best edition of his works, which were written in correct and elegant Latin, is that published by the College of Physicians in 1 vol. 4to., in 1766, with an engraving by Hall from the portrait by Cornelius Jansen, in the college library. A life of Harvey by D. Willis, and a translation of his works, have also been published by the Sydenham Society.

HARWICH, a parliamentary and municipal borough and port in Essex, at the mouths of the Stour and Orwell. It is 70 miles from London by the Great Eastern Railway. The parliamentary and municipal bounds are coextensive, and include the parishes of St. Nicholas and Dovercourt. The area is 3306 acres, and the population, in 1861, was 5070.

The chief buildings of interest are the parish churches, town hall and sessions court, new railway hotel, custom-house, gaol, free school and almshouses, Martello tower, circular redoubt, &c. A fine esplanade extends southward from the town, from which good views of the harbour and the German Ocean may be obtained.

There are large manufactories of cement (made from stone dredged at sea off the harbour), and of artificial manures. Fishing and shipbuilding are also carried on. The harbour of Harwich is said to be the best on the east coast of England, being large enough to afford sufficient anchorage for 100 sail of the line in five fathoms of water. It has recently been made a harbour of refuge, as it is the only place between Yarmouth Roads and the Thames capable of affording shelter to vessels during easterly gales. Within the last forty years, however, the sea has made very considerable encroachments on the coast, and already undermined the battery by which the town is defended, which was erected so lately as 1820. Formerly Harwich was the ordinary port of departure from England to the Netherlands; but after the French war its trade rapidly declined, and it was for many years visited principally for sea-bathing. Recently (1864-65), however, its commerce has greatly revived, in consequence of the Great Eastern Railway Company having established a line of steamers from Harwich to Rotterdam in connection with their railway, thus materially reducing the time required for a journey from London to Holland. The experiment is considered to have been perfectly successful, and the business on the route is rapidly increasing, especially in respect to the importation of cattle. The number of vessels registered as belonging to the port in 1865 was 119 (7890 tons). The

entries in 1864 were 887 (138,241 tons), and the clearances 742 (115,298 tons). The customs revenue in 1863 was 1849*l.*; in 1864 it had increased to 2443*l.*

The borough of Harwich sends two members to the House of Commons, the number of electors being about 360. Harwich was the Saxon Harevich.

HARWOOD, REV. DR. THOMAS, perpetual curate of Hammerwich and Burntwood, and a learned scholar and divine, was born at Sheperton, Middlesex, in 1767. He was educated at Eton, and afterwards graduated as B.D. and D.D. at Emmanuel College, Cambridge. In October, 1791, he was elected head-master of the grammar school at Lichfield. In 1800 he was appointed perpetual curate of Hammerwich, and in 1828 was presented to the chapelry of Burntwood, near Lichfield. He was the author of various works, chiefly of a classical or theological character. In 1789 he published 'Annotations upon Genesis;' in 1794 two volumes of sermons; in 1797, 'Alumni Etonenses;' in 1798, 'The Sacred History of the Life of Jesus Christ, illustrative of the Harmony of the Four Evangelists;' in 1801, 'Grecian Antiquities;' in 1804, 'A Manual of Geography,' and 'The History of Lichfield;' in 1819, an edition of 'Erdeswick's Staffordshire;' and in 1826, 'Annotations upon the Liturgy.' To his various studies he devoted a long and industrious life; and independently of the works which he laid before the world, he has left a large collection of interesting criticisms connected with topography, antiquities, and general history. He died in 1843.

HASBERA, a village of Syria, 36 miles W. of Damascus, in a deep glen on a ridge of Mount Hermon. Population, 4000 Christians and 1000 Druses. A Protestant mission was established here in 1846, and in 1860 it was nearly ruined during the Druse massacre, when most of the Christians fled for shelter to Sidon and Tyre.

HASLINGDEN. [LANCASHIRE.]

HASSELQUISTIA, a genus of plants belonging to the natural order *Umbelliferae*, and to the tribe *Tordyliaceæ*. The species closely resemble those of *Tordylium*, and are regarded by some botanists as monstrous forms of this genus.

HASELT. [LINBURG.]

HASTINGS. [SUSSEX.]

HASTINGS, FRANCIS RAWDON, EARL OF MOIRA, and MARQUIS OF, was born in Ireland in 1754. On the breaking out of the American war, his lordship entered enthusiastically into the ranks of the British Army; and in 1775 embarked for the scene of action. In 1778 he was nominated adjutant-general to the British army in America, with the rank of lieutenant-colonel. Here he was engaged in most of the desperate combats which have been recorded in the history of that unfortunate struggle—as the battles of Bunker's Hill, of Camden, Hobkirk's Hill, &c. On his return to England he was created a British peer, and soon afterwards despatched to Holland with 10,000 men to aid his Royal Highness the duke of York. In 1803 his lordship was appointed commander of the forces in North Britain. Shortly afterwards he received the important office of governor-general of Bengal, and at the same time he was appointed commander-in-chief of the army in the East Indies, which he held until 1822. His next appointment, after his return

to England, was as governor of Malta, in which situation he died in 1826.

No governor-general ever held power in India for so long a time, or with more wisdom, energy, and moderation. In his civil administration he was tolerant to the prejudices of the natives, and favourable to the advancement of knowledge. Under his rule and directions the formidable contests with the Mahrattas, the Pindarees, the Nepaulese, and other hostile foes, were brought to a favourable conclusion, and the subjugation of our Indian territories consolidated.

HASTINGS, WARREN, the chief founder and organizer of the British Empire in India, was born on 6th December, 1732, and, after receiving the usual education at Westminster School, went out in 1750 as a writer in the service of the East India Company. After residing about fourteen years in India, he returned home with a moderate fortune. In 1769 he received the appointment of second in council at Madras, and in 1772 was appointed President of the Supreme Council of Bengal. His powers were enlarged by the alteration of the Indian constitution by act of Parliament, in virtue of which he became, 1st January, 1774, governor-general and supreme head of all our Indian dependencies. Affairs were at this time in great disorder, but he weathered the dangers to which the British Empire in India was exposed. Notwithstanding his services, he gave satisfaction neither to the home administration nor to the Court of Directors. The public ear was offended by rumours of cruelty, corruption, and unjust aggression; the Directors censured the lavish and corrupt expenditure, and the independence of his conduct. Repeated attempts were made to obtain his dismissal, but these were uniformly defeated by the Court of Proprietors. Thus supported, he carried matters with a high hand; neglected or positively refused to obey the orders sent by the Directors; overruled the opposition of the Council, of which a majority was, in the first instance, opposed to his views [FRANCIS, SIR PHILIP], and practically exercised an absolute and irresponsible power until February, 1785, when he resigned his office and set sail for England. On his arrival he was received at Court and elsewhere with great favour, and it was thought that rewards and honours—a peerage among them—would be lavishly conferred on him. But, by and by, instead of recompense arose a murmur about punishment—and then that celebrated indictment was prepared, that notable process begun, which afforded Burke, Fox, and Sheridan an opportunity for the display of their eloquence, but which in other respects was entirely fruitless. In the session of 1786, articles of impeachment were brought forward by Mr. Burke, charging him with the oppression and final expulsion of the rajah of Benares; the maltreatment and robbery of the Begums (or princesses) of the house of Oude; and the charges of receiving presents and conniving at unfair contracts and extravagant expenditure. The sessions of 1786–87 having been consumed in preliminary proceedings, the House of Lords assembled in Westminster Hall, February 13, 1788, to try the impeachment, and on the 15th, Mr. Burke, in the name of the Commons of England, opened the charges against the prisoner in a speech which lasted upwards of three days.

[BURKE.] He was assisted in the management of this cause by Fox, Sheridan, Grey, and others. The sessions of 1788, 1789, and 1790 were consumed in going through the case for the prosecution. In 1791 the Commons expressed their willingness to abandon some part of the charges, with the view of bringing the trial sooner to an end; and on the 2nd of June, the seventy-third day, Mr. Hastings began his defence. This was protracted until April 17, 1795, on which (the 148th) day, after a lingering trial of seven years, he was acquitted by a large majority of the House of Peers on every separate article charged against him.

Mr. Hastings attempted to refute the charges of extortion by publicly asserting, in the most solemn manner, that never at any time of his life was he worth 100,000*l*. The law-charges of his defence amounted to 76,080*l*. In March, 1796, the Company granted him an annuity of 4000*l*. for twenty-eight years and a half, and lent him 50,000*l*. for eighteen years, free of interest. He retired completely from public life, to an estate which he purchased at Daylesford in Worcestershire. He died August 22nd, 1818, having been raised to the dignity of privy-councillor not long before.

Hastings, whose enterprises were so gigantic, was small in stature, but vigorous in frame. His chief misfortune was, that born a gentleman and educated a scholar, he had to begin life as a commercial adventurer: Government was to him an audacious commercial speculation, which he strove in vain to hide by viceregal splendour.

HAT, a well-known covering for the head. Hats are made of silk, fur, wool, straw, and many other materials. The curious art of felting is believed to have been brought to Western Europe by the Crusaders. Wool was the material first used in making felt hats; but in time, as trade with America became developed, it was superseded by the fur of the beaver, and for many years, fine beaver hats, in the manufacture of which great skill and care were required, were worn by the higher and middle classes in Great Britain. About the year 1830 it was estimated that a million beavers were annually killed to supply the hat trade in Europe. This led to a great scarcity of beaver fur, and to the substitution of silk, which now forms the most important article in the manufacture of hats. The silk hat consists of a body and rim usually made of two or three layers of cotton cloth, saturated with varnishes to give the fabric stiffness, and make it waterproof. These are moulded on wooden blocks according to the fashion of the day, and then the shape is covered with lac and dammar varnish, and the fine silk plush is applied with great nicety, so as to make it adhere in every part, and to render the seam as imperceptible as possible. It is then trimmed with silk braid on the edge of the brim, and a silken band round the junction of the body with the brim, and a lining of leather and silk put in to complete the hat. Plush is largely made in England for covering silk hats; but the best, for the so-called 'Paris hats,' comes from France. Lightness, gloss, and durability, are the chief qualities of this kind of hat, but it is easily damaged, and quite unsuitable for rough wear in travelling or out of door pursuits; and hats of felted wool, of the slouch or wide-awake form, are very much worn, especially in the country.

The importation of hats into the United Kingdom in 1863 was as follows:—Of felt, 151,278, value 45,388*l*., nearly all from France and Belgium; of hair, wool, or beaver, 3053, value 1221*l*.; and of silk, 582, value 86*l*. In the same year were exported, principally to the colonies, 1,241,544 felt hats of British make, and 21,427 foreign, total value 229,865*l*.; 81,102 silk hats, value 32,464*l*., were also exported in 1863. For the trade in, and manufacture of straw hats, see STRAW PLAIT.

HATCHETINE. *Mineral Adipocere*. This substance occurs in thin flakes in the cavities of the ironstone of South Wales. It is very soft, somewhat granular in appearance; translucent; colour yellowish white or greenish; not elastic; inodorous; combustible. It melts at 170°, and is soluble in ether. It consists of C¹ H¹.

HATCHMENT, sometimes called *achievement*, is the funeral escutcheon of the higher classes generally placed in front of the house after their death, and sets forth the rank of the deceased. It is in the form of a diamond, and usually about three or four feet square; the border or framework being black, and the arms of the deceased impaled in the centre on a black ground.

HATCHWAYS are openings in the deck of a ship, leading from one deck to another, and generally used for hoisting or lowering goods. The number of hatchways varies according to the size and use of the ship, being most numerous in merchant vessels and barges.

HATHERLEIGH. [DEVONSHIRE.]

HATEMISTS, a fanatical sect of Dutch Calvinists, who flourished in the province of New Zealand, in the seventeenth century, and were so called from Pontian Van Hattem. He maintained the system of a fatal and uncontrollable necessity, and held that mankind were under no kind of obligation to obey the divine laws.

HAUBERGEON, or HAUBERK. [ARMOUR.]

HAUGHTON, WILLIAM, a dramatic writer, was probably somewhat the junior of Shakspeare. In Henslowe's Diary, under the date of November, 1597, he is called 'Young Haughton;' and his name occurs frequently in that curious record till the end of the year 1600, but not later. He wrote several plays unassisted; in others his coadjutors were Chettle, Day, and still more frequently Dekker. In 1600 there was licensed a tragedy of his, not preserved, called 'Ferrex and Porrex;' and Mr. Collier has conjectured that Haughton's 'Devil and his Dam,' described as in progress about the same time, may have been an alteration of 'Grin, the Collier of Croydon.' But the only extant plays in which Haughton was certainly concerned are two. 1. He was sole author of the lively comedy called 'Englishmen for my money; or, a Woman will have her Will,' which (under the latter title) appears in Henslowe's book in 1598. It was printed in 1616, in 1626, and 1631, and has been reprinted in a small collection called 'The Old English Drama,' 1830, 4 vols. 12mo. 2. Dekker, Haughton, and Chettle were jointly the authors of 'The Pleasant Comedie of Patient Grissill,' which was entered at Stationers' Hall in March, 1600, printed in 1603, and reprinted from a very rare copy by the Shakspeare Society in 1841.

HAUKAL, ABUL KASEM MOHAMMED IBN, a celebrated Arabic traveller and geographer. The few particulars we possess concerning his life are derived from his own work. Partly to avoid the tyranny of the reigning sultan, and to improve his own fortune by trade, he set out from Bagdad, A.H. 331 (A.D. 942-43), to visit foreign countries. He does not tell us into what countries he travelled; but we learn from his own account that he was in Mesopotamia, A.H. 358 (A.D. 968-69); in Africa, A.H. 360 (A.D. 970-71); in Sicily, A.H. 362 (A.D. 972-73); and in Mecca, A.H. 364 or 365 (A.D. 974-75 or 975-76).

Haukal's work on geography is entitled 'A Book of Roads and Kingdoms.' The description of each country is accompanied by a map.

Manuscripts of Haukal's work on geography are rarely met with even in the East. There is a copy in the Bodleian Library at Oxford, and another at Leyden. From the latter MS. Uylenbroeck has given an interesting account of the work in his 'Iracæ Persicæ Descriptio: præmissa est Dissertatio de Ibn Haukali Geographi codicis Lugduno-Batavo,' 4to., Lugd. Bat., 1822.

Ouseley published, from what he conceived to be a Persian translation of the Arabic of Haukal, a work entitled 'The Oriental Geography of Ebn Haukal, a traveller of the tenth century,' London, 1800; and De Sacy gave a further account of this work in the 'Magasin Encyclopédique,' vol. vi., pp. 32-76, 151-186, 307-333. But Uylenbroeck has shown that the Persian treatise translated by Ouseley cannot be regarded as either a translation or an abridgment of the Arabic of Haukal. He considers it probable that the Persian work was one of those which Haukal made use of in compiling his Geography, and that it was written by Ibn Khordadbeh.

HAUKSBEE, or HAWKSBE, FRANCIS, was born in the latter part of the seventeenth century. He was admitted a fellow of the Royal Society in 1705, and between 1705-11 there appeared several papers in the 'Philosophical Transactions,' giving an account of his experiments in electricity. In 1706 he recognized the electricity of glass by friction, and was thence led to the construction of the electrical machine. In 1709 he published his 'Physico-Mechanical Experiments on various Subjects, touching Light and Electricity producible on the Attrition of Bodies,' London, 4to.; and in 1731, 'Proposals for a Course of Chemical Experiments,' 4to. In the same year he published 'An Essay for introducing a Portable Laboratory.'

HAUSMANITE, a mineral found in the Hartz Mountains, near Ihlefeld, which crystallizes in octahedrons. Its colour is of a brownish black, with an imperfect metallic lustre. Its specific gravity is 4.8.

HAUTOBOIS. [OBOE.]

HAUTEFEUILLE, JEAN DE, a French mechanician, was born at Orleans, March 20, 1647. His father was a baker, but the duchess of Bouillon, to whom the young man was introduced, paid the expense of his education, and engaged him to enter into the ecclesiastical state.

The Abbé Hautefeuille devoted himself to the study of subjects connected with physical science, and to the construction or improvement of instruments; but he is distinguished chiefly by the claims

which he advanced, in 1675, to the honour of having invented a spring-balance for watches. About the same time Huyghens invented, for the like purpose, a spring, which he made of a spiral form; and it is remarkable that Dr. Hooke had, about the year 1658, invented a balance-spring for watches, but he spent several years in improving his escapement, and his watches were not made public till about the same year that the inventions of Hautefeuille and Huyghens were in use in Paris.

Hautefeuille published a method of finding the declination of a magnetic needle (1683); an account of a magnetic balance (1702); with accounts of a micrometrical microscope, and of an instrument for observing the altitudes of celestial bodies. He also published, in 1719, a work entitled 'Nouveau Système du Flux et Reflux de la Mer,' in which the phenomena of the tides are made to depend upon a particular motion which he ascribes to the earth: but the best of his works is his 'Dissertation sur la Cause de l'Echo,' which had been read before the Academy of Bordeaux in 1718, and was published in that city in 1741. He died October 18, 1724.

HAUTE SAVOIE. [SAVOIE, HAUTE.]

HAÛY, RENE'-JUST, ABBE', was born 1743, at St. Just, in the present department of Oise. He commenced his studies at the college of Navarre, to which college he was appointed professor in 1764, and subsequently also to that of the Cardinal Le Moine. He was the first to show that the structure of crystalline substances was regulated by laws as invariable as those to which organized bodies are subjected. His theory rests upon the supposition that all the crystalline forms belonging to any single species of mineral, are derivable from some one simple form which may be regarded as the type of the species. He received many scientific appointments in France. He died at Paris, June 3, 1822. Besides numerous memoirs upon mineralogy and electricity, inserted in the *Journal des Mines*, and the *Annals of the Museum of Natural History*, he has left the following works: 'An Essay on the Structure of Crystals,' 1 vol., 1784; 'Exposition of the Theory of Electricity and Magnetism,' 1 vol.; 'Treatise on Mineralogy,' 4 vols., 1822; 'Treatise on Physics,' 2 vols., 1821; 'Treatise on Crystallography,' 2 vols., 1822; and some others.

HAÛYNE. *Latialite*. This mineral occurs in rhombic dodecahedral crystals, of a bluish green colour. The massive varieties are amorphous; structure granular, compact. The composition is complex, but consists chiefly of silica, alumina, potash, lime, and sulphuric acid.

HAVAGE, an ancient and almost obsolete term, signifying race or family connections.

HAVANNAH, or HAVANA, a flourishing commercial town, with the best harbour in the West Indies, or perhaps in the world, stands on the north coast of the island of Cuba, in 23° 9' 4" N. lat., 82° 22' W. long., and in 1861 had a population of 196,847. A channel half a mile long, 350 yards broad, 8 to 10 fathoms deep, and without bar or obstruction of any sort, leads to the harbour, which is formed by a magnificent bay nearly three miles long, and half as much in width, sheltered by hills from every wind, and capable of accommodating a thousand ships of the largest size, vessels of the

greatest draught coming close up to the quays. The city is built along the entrance to, and on the west side of, the basin. In the city the streets are narrow and dirty, but in the suburbs, which are now larger than the city, they are wide and well laid out. Of late years, too, all parts of the town are much improved in cleanliness, and less unhealthy in summer than formerly. The entrance to the harbour is defended by two strong fortresses, El Morro and La Punta, and a continuous series of batteries runs along both shores. The city also, which is entered by three gates, is defended by a strong citadel; and fortifications have been erected on all the neighbouring heights. The cigars of Havannah are of world-wide celebrity. It has also manufactures of chocolate, woollen fabrics, and straw hats. Most of the mercantile nations have establishments in the city. British, Germans, Dutch, Belgians, and Americans are very numerous. The shops contain displays of the most costly articles of European manufacture. In general the houses are of only one story, but of very solid construction; the windows are unglazed, and always kept open on account of the heat of the climate. Among the finest public buildings is the cathedral, in which the remains of Columbus now lie, having been removed hither from San-Domingo in 1795. The opera-house is one of the most magnificent in the world. Other large structures, more remarkable for solidity than elegance, are the two hospitals, the residence of the Captain-General near the citadel, the naval arsenal, the post-office (correo), and the great tobacco factories. Havannah is the seat of a bishop, has a university, with medical and law schools, an ecclesiastical college, theatres, a botanic garden, museum of natural history, school of painting, dockyard, newspapers, and three fine promenades, one along the ramparts, one within the town, and a third without the walls (Paseo Extra-Muros). These walks are shaded with trees and adorned with fountains. There are railways to the places of most importance in the interior.

A glance at the map shows the great importance of Havannah in a political point of view, commanding as it does both the inlets to the Gulf of Mexico. Among the commercial cities of the western hemisphere it ranks inferior only to New York, and for a long period it engrossed the whole foreign trade of Cuba; but of late years a portion has been obtained by Matanzas, a town about 60 miles E. The principal articles of export are sugar, copper ore, coffee, raw tobacco and cigars, and molasses; other exports are mahogany, cedar, rum, cocoa, cotton, wax, hides, fruits and preserves, honey, dye-stuffs, &c. The imports are composed of flour, corn, provisions, cotton goods, wine, linen, hardware and metals, silk, spices, leather, butter, lard, cheese, fish, deals, casks, hoops, &c. The trade of Havannah extends to all countries of Europe and America, but chiefly to Spain, the United States, and England.

The chief landholders and capitalists at Havannah have for some time been engaged in considering a scheme for the gradual abolition of negro slavery. The plan is based upon the principle of the slave emancipating himself by his own labour. It seems to have been received with a considerable degree of favour, for the feeling in the island of Cuba that a change in the relations between the proprietors

and the slaves is imminent is general, and the desire seems to be as general that, whatever the change, it should be a step toward complete emancipation.

HAVANT. [HAMPSHIRE.]

HAVELOCK, GENERAL SIR HENRY, an illustrious soldier, whose skill and bravery nobly retrieved English honour in British India, was born, April 5, 1795, at Bishopwearmouth, in Durham. He was educated at the Charterhouse School, and in 1813 was entered of the Middle Temple, where his most intimate associate was the late Judge Talfourd, author of 'Ion.' His elder brother, Lieutenant-Colonel William Havelock, having distinguished himself in the Peninsular war and at Waterloo, he became in turn inspired with the military ardour of his family. A month after the battle of Waterloo he was appointed, by purchase, second lieutenant to the Rifle Brigade; and he had the good fortune, in his military training, to have the assistance of Captain, afterwards Sir H. Smith, the hero of Aliwal. Having subsequently exchanged into the 13th Light Infantry, in 1823 Havelock departed for India; and in the Burmese war, which broke out in 1824, he was appointed deputy-assistant-adjutant-general. He was present at the actions of Napadee, Patangoh, and Peghan. Being an accomplished scholar and a linguist, our hero, in 1827, published the 'History of the Ava Campaigns,' which was remarkable for the freedom of its comments on the circumstances of the war. Notwithstanding the talents he everywhere exhibited, and the learning he displayed on his passing for languages at the college of Calcutta, he remained for twenty-three years a subaltern. About this period, an army was collected for the invasion of Afghanistan. Havelock accompanied the British forces, and was present at the capture of Ghuznee and Cabul. He afterwards published a 'Narrative of the Afghan Campaign,' which was highly appreciated for its style and fidelity. On the second invasion of Afghanistan, Havelock was sent to join Sir R. Sale, at Jellalabad, and was present at the various encounters with the Ghilziees. He had also the chief direction, under General Sale, of the memorable defence of that place, of which he wrote the despatches, so highly commended by Sir G. Murray. In the crowning attack upon the forces of Akbar Khan, and their final defeat, Havelock commanded the right column, and broke the enemy's lines before the main forces of the British could enter into action. For this gallant deed he was made a Companion of the Bath, and gazetted to a brevet-majority.

The following year Sir Henry Havelock was promoted to a regimental majority, and nominated interpreter of the Persian language to the commander-in-chief, Sir Hugh Gough. In 1844 he was promoted to the rank of lieutenant-colonel, by brevet. In 1845 he was actively engaged in the war against the Seiks, and took a conspicuous part in the battles of Moodkee, Ferozeshah, and Sobraon, in which he had three horses shot under him. He was afterwards appointed deputy-adjutant-general of the Queen's troops at Bombay; but twenty-five years of ever active service beginning to make an impression on his constitution, he visited Europe for the renovation of his health. On his return to Bombay, in 1851, he was made brevet-colonel, and

appointed, through the interest of Lord Hardinge, quartermaster-general, and the adjutant-general of the Queen's troops in India. During the short war with Persia, Sir Henry had the command of the second division, and was engaged in the action of Mohammerah. In the meantime the sanguinary rebellion of the Indian Sepoys had broken out, and Havelock, on his return from the Persian campaign, was sent up to Allahabad as brigadier-general, when he was frequently engaged with the overwhelming forces of the sanguinary rebel Nana Sahib. He defeated his formidable enemy in nine pitched battles, took about one hundred pieces of cannon, recaptured Cawnpore, and rescued Lucknow and its brave defenders from the impending horrors that had been perpetrated at Delhi and Cawnpore. But at length, worn out by unceasing toil and constant exposure, he was seized with a mortal disease, and expired at Lucknow on the 25th of November, 1857.

HAVER, in Scotch law, is one who holds a deed, writing, or other document required in a cause, either for inspection or in evidence, and who is called upon to exhibit it judicially. The right of litigants to call on third parties to produce documents in their possession, is regulated by the same principles as those which compel their attendance as witnesses. No one is bound to produce a document which might injure himself; under this limitation, that either party to a cause may call upon his adversary to exhibit a writ necessary to his case, provided that writ is particularly specified or described. Parties cited as havers must either produce the documents required, or depose that they neither have them, nor have had them since the date of citation, nor have fraudulently put them away, nor know or suspect where they presently are. (Erskine, *iv.* 1, 52; *Stair iv.* 33, 2, and *iv.* 41, 5.) The method employed to compel production is by letters of incident diligence. (Shand's 'Pract.,' i. 369.)

HAVERFORDWEST. [Pembrokeshire.]

HAVER, or HAVER-DE-GRACE, LE, a large commercial town and fortified seaport in the department of Seine-Inférieure in France, stands in a low marshy spot on the southern shore of the English Channel, at the embouchure and on the right bank of the Seine, in 49° 29' N. lat., 0° 6' 33" E. long., distant by railway 134 miles from Paris, 24 W. from Rouen, and has 74,336 inhabitants. On the decline of Harfleur in the latter half of the fifteenth century, Louis XII. in 1509 laid the foundation of Havre, threw up some fortifications, and built two short jetties. His successor, François I., by the sums he expended on the town, and the great privileges he conferred upon it, is however to be looked on as the true founder of Havre. In this reign the new city was in great measure built, the harbours improved, the town-hall and the ramparts erected, and the Tower of François I., which still subsists, constructed for the defence of the harbour. In 1562 the Prince de Condé betrayed the town to Queen Elizabeth, who garrisoned it with 6000 troops under Dudley, earl of Warwick. The English were forced to capitulate in 1563, but carried away as a memorial of their occupation the archives of the town. Louis XIII. added to the fortifications, and built a citadel, which was afterwards rebuilt on a new plan by order of Cardinal Richelieu. Under Louis XIV. the extent

of the town was nearly doubled; part of the fortifications and the old gate of Ingouville were demolished, a new quarter built, and the citadel converted into an immense military quarter, which comprises an arsenal, governor's residence, ammunition stores, and large barracks, forming together a spacious and handsome square round the Place d'Armes. Other fortifications were afterwards erected, but as they became a nuisance from the obstruction they presented to the extension of the town, they have recently been demolished, and Havre has now absorbed the neighbouring communes of Ingouville and Gravelle l'Heure.

The town is entered by several gates with draw-bridges; of which the Porte-Royale, in form of a triumphal arch, is the most remarkable. The old part of the town, which is built round the harbour, presents regular but narrow streets. The wooden houses, of which it was formerly composed, have gradually given way to more solid and sightly structures. The new part is built on a regular plan; the streets are wide, cross each other at right angles, and present several handsome houses. The principal street in Havre is the Rue de Paris, which presents more commercial activity than is seen even in Paris. There are few buildings that call for special notice; besides those already mentioned may be named the church of Notre-Dame, the new city hall, built in the style of the Tuileries, the mansion-house, the custom-house, the exchange, the great tobacco factory on the Quai d'Orléans, the bonding warehouses, the public library, which contains 20,000 volumes, the theatre, and the Frascati baths on the sea-shore. Tribunals of first instance and of commerce are held in the town, which has also a chamber of commerce, a naval school of the first class, a school of applied geometry, several insurance offices, &c.

A singular local phenomenon respecting the tide, which rises at Havre to 20 and 27 feet, gives an important advantage to the harbour. It results from the position of the harbour with respect to the Seine that the tide having reached its maximum continues *full for three hours*, in consequence of the strong current of the river damming up the water in the channel formed by the jetties; and this exception to the general tidal law gives vessels leaving the harbour time to reach the sea, even against a head wind, in a single tide. The fine quays which border the docks are always lined with vessels, and present great activity of business.

The harbour of Havre is one of the most accessible in France. It is entered by a narrow channel, which is formed by two long jetties, running nearly E. and W., and built between two banks of shingle, and which, owing to the current, require little dredging. The channel leads to the outer harbour, which is occupied by a large number of coasters, and within it are capacious wet docks, capable of accommodating 500 ships. The largest is L'Eure, which contains 700,000 square feet. An immense dry dock has just (1865) been completed, to obviate the necessity of sending large steamers to Southampton for repairs.

Havre has become the Liverpool of France, as the principal site of communication with transatlantic countries. It receives three-fourths of all the cotton imported into France, ships most of the French exports to America, and, generally speaking, possesses

about a fifth of the entire trade of the country. The exports and imports together are now (1865) nearly 60,000,000*l.* per annum. The imports consist chiefly of cotton, spices, coffee, tea, sugar, timber, coal (from England), &c.; and the exports of French manufactured goods, wine, brandy, oil, jewellery, provisions, &c. It formerly had several vessels engaged in the whale fishery, but of late years this employment has been discontinued. It has direct communication with Great Britain, Holland, Hamburg, Portugal, Mexico, Brazil, United States, India, &c.

The British consul at Havre, in his report for 1865, states that, in 1864, 1106 vessels from the United Kingdom entered the port. Their cargoes consisted of coals, cotton, iron, copper, machinery, lead, petroleum, cement, general manufactured goods, &c., and their united tonnage was 305,154. He says, a revolution is slowly but surely taking place in thoughtful minds, which cannot but beneficially affect the maritime commercial relations of France, and particularly the prosperity of the port of Havre, which has so long been kept back by the differential duties levied on foreign ships frequenting it. It begins at length to be perceived by all discerning minds, that heavy taxes levied on foreign ships, and materials of which ships are built, create a monopoly in favour of French vessels which adds little to the national wealth, whilst they, by discouraging a free and profitable intercourse with foreigners, exclude the advantages which arise from free competition in trade, and hamper commercial undertakings with vexatious regulations and formalities, that prevent many foreign vessels from repeating their visits to the port. Considerations of this kind, which for some time have occupied the attention of the superior council of commerce, and indeed of the Government, have brought the council to recommend the abolition of all tonnage duties now leviable upon foreign vessels entering the ports of France, upon the ground that they are injurious to the general industry of the country, the interests of consumers, and of the mercantile marine of France.

The council adduces as a proof of the good effects that may be expected from this radical change of system, the prosperous state of trade at the port of Marseilles, since the tonnage duties levied upon foreign ships arriving there were abolished. These opinions appear to have received the sanction of the Emperor.

Havre has direct railway communication with Paris, and the continuation of the line to Strasbourg has afforded such facility of communication with Germany, that the greater part of the trade of that country with America is carried on through Havre.

The town has extensive manufactories of paper, sulphuric acid, tobacco, cotton goods, starch, lace, oil, machinery, ropes, and salt. There are also some sugar refineries, and several shipbuilding yards, which have constructed some of the best sailing vessels and swiftest steamers belonging to France.

The handsome suburb of *Ingouville* is built on a high hill overlooking the town, the harbour, and the sea, and contains many pretty country seats belonging to the merchants of the town. Havre itself lies on low ground, and has often suffered from the sea in violent hurricanes.

HAWFINCH, *Haw Grosbeak*, *Grosbeak* of the English; *Le Grosbek* and *Pinson Royal* of the French; *Frogione*, *Froccione*, *Frosone*, *Frisone*, *Friggione* of the Italians; *Kernbeisser*, *Kirsch-Kernbeisser*, *Kirschfink*, *Nussbeisser* of the Germans; *Loxia Coccothraustes* of Linnæus; *Fringilla Coccothraustes* of Temminck; *Coccothraustes vulgaris* of Brisson.

Description.—Rump, head, and cheeks red-brown; edging round the bill, space between that and the eye, a line beyond the eye and throat, deep black; a large ash-coloured collar just below the nape; back and greater part of the wings deep brown, but there is an oblique white stripe upon the wing, and beyond it a considerable space of a light whitish colour

Hawfinch (*Coccothraustes vulgaris*).

going off into chestnut; secondary quills as if cut off square at the ends, or, as Edwards says, with justice, like the figures of some of the ancient battle-axes, glossed with rich blue, less conspicuous in the female; tail feathers white within, of a blackish brown on the external barbs; lower parts of the bird vinous red; iris pale red (according to Temminck), feet and bill grayish brown. Length seven inches.

Female, generally like the male, but with the colours much less brilliant.

The young of the year before the moult are very different in their plumage from the adult birds. Throat yellow; face, cheeks, and summit of the head dirty yellowish; lower parts white, or whitish; sides marked with small brown streaks, with which all the feathers are terminated. As the young bird advances in age, some red vinous feathers appear disposed irregularly upon the belly; the upper parts are of a tarnished brown spotted with dirty yellowish; bill whitish brown, except at the point, where it is deep brown.

The Hawfinch is plentiful in some districts of France, as well as in Germany, Sweden, and parts of Russia. It is not uncommon in Italy. In our island the Hawfinch is not often to be seen, probably more on account of its reclusive habits than its actual rarity. Selby and others have remarked that this bird is only an occasional visitant, but it has been satisfactorily proved by Mr. Doubleday that it is not migratory, but remains with us during the whole year, inhabiting dense woods, and invariably perching on the topmost branches of the tallest trees: it builds, however, in dense bushes.

Hard seeds and kernels form the principal food of the Hawfinch or Grosbeak, but it feeds also on the berries of the hawthorn, whence its name.

HAWHAW, a fence or bank that interrupts an alley or walk sunk between slopes and not perceived till approached.

HAWICK. [ROXBURGHSHIRE.]

HAWK. [FALCONIDÆ.]

HAWK MOTHS (*Sphingidæ*), a family of lepidopterous insects known also by the name of the *Sphinx moths*. The body is thick and stout, the antennæ are thickened in the middle or towards the end, and terminate acutely. The wings are comparatively narrow, and traversed by strong nervures. The habits of some are nocturnal, of others diurnal. The metamorphosis is complete. The caterpillar lives on the leaves of shrubs and trees. The best known hawk moths are the Privet moth (*Sphinx ligustri*) and the Death's Head moth (*Acherontia atropos*). The genus *Deilephila*, or twilight moth, contains a number of species noted for the elegance of their forms and the beauty of their colouring.

HAWKE BAY, is the name of a provincial government of New Zealand, in the north of that island, and which, till 1858, formed part of the province of Wellington. The capital is Napier; and the extent of the territory is 2,639,200 acres, or 4122 square miles. The value of the exports is about 60,000*l.* per annum. In 1863 the population was 2,300, and 4,000 aborigines.

HAWKER. [PEDLAR.]

HAWKESWORTH, JOHN, LL.D., was a successful writer of the last century. The date of his birth (1715 or 1719) and the occupations of his early life are variously stated. In so short a notice, all that is essential to record is that he was bred to some mechanical occupation, and therefore deserves the more credit for his talent and industry in supplying the defects of a rude and illiterate education. His first appearance was as a contributor to the 'Gentleman's Magazine,' in which he succeeded Dr. Johnson as compiler of the parliamentary debates in 1744. In 1752 he undertook, assisted by Johnson, Warton, and one or two others, a series of essays, called the 'Adventurer.' They extended to the number of 140 (seventy of which are ascribed to Hawkesworth himself), and were received with great approbation. Herring, archbishop of Canterbury, was so much pleased with the work, that he procured a degree in civil law for the conductor. In 1761 he published an edition of Swift, with a life prefixed. On the return of Captain Cook from his first voyage of discovery in the South Seas, he compiled an account of the voyage in three vols. 4to., 1773 [COOK], and received for recompense the liberal sum of 6000*l.* The work, however, did not give entire satisfaction; exceptions were taken to the warmth of his descriptions of manners, and to his religious speculations. The chagrin occasioned by these censures is said to have shortened the author's life. Dr. Hawkesworth translated 'Telemachus,' and wrote 'Almorán and Hamet,' an eastern romance, which was much admired. He was a regular contributor to the 'Gentleman's Magazine.'

HAWKING. [FALCONRY.]

HAWKINS, SIR JOHN, a distinguished seaman of the reign of Elizabeth, was born in Plymouth in

1520. His youth was spent in trading to Spain, Portugal, and the Canaries. With the assistance of some merchants, he fitted out a small squadron in 1562, and obtained, partly by purchase, partly by force, a cargo of 300 negroes, whom he carried to Hispaniola, and there sold. This, we believe, was the first adventure of Englishmen in that inhuman traffic. He made a second voyage in 1564, and a third in 1567: the latter turned out unfortunately. He was attacked by the Spanish authorities in the port of S. Juan de Ulloa, and saved but two ships of his squadron, with which, after suffering great hardships, he returned to England in January, 1568. In 1588 he served as rear-admiral against the Spanish armada [ARMADA], and was rewarded with the honour of knighthood. Being sent with Frobisher in 1590 to intercept the Plate fleet and harass the trade of Spain, he failed in the first object, but succeeded in the second. In 1595 he was appointed, jointly with Drake, to command a more important expedition against the Spanish settlements in the West Indies. This enterprise proved fatal to both these hitherto successful commanders. [DRAKE.] Hawkins died November 21, 1595. Sir John Hawkins sat in Parliament for Plymouth, and founded an hospital at Chatham for poor and sick seamen.

HAWKINS, SIR JOHN, the biographer of Johnson and the historian of music, was born on the 30th March, 1719. He was articled to an attorney, and remained in the law till 1759, when he retired with a competent fortune. While in the law, he cultivated the study of music, and associated with Dr. Johnson and other literary men. Between 1759 and 1772 he served as a Middlesex magistrate; and it was for his efficiency in this office that he was knighted.

Sir John Hawkins now set seriously about finishing a work which has gained a European reputation, his 'History of Music.' He went to Oxford, and there remained some time, to examine the books, in the Bodleian and other libraries, connected with his inquiry; and he spent two or three years in similar researches in other quarters. In 1776 the work appeared, in five quarto volumes, under the title of 'A General History of the Science and Practice of Music.' The work was appreciated by learned musicians; but Dr. Burney published a similar history about the same time, smaller in bulk and more pleasing in style; and other circumstances led to a series of most virulent attacks against Hawkins and his work, so that his 'History' fell almost dead from the press.

Time, however, has done that justice to the author which his contemporaries denied him.

Sir John Hawkins afterwards published an edition of Walton's 'Angler' and a 'Life of Dr. Johnson.' He purchased and presented to the British Museum Dr. Pepusch's valuable musical library. He died in 1789, leaving behind him a high character both for moral and intellectual qualities.

HAWKSHEAD. [LANCASHIRE.]

HAWKSMOOR, NICHOLAS, who executed many buildings of note in the early part of the last century, was born in 1666, and at the age of seventeen became the pupil of Sir Christopher Wren. His style partook of the massive and heavy, combined with a certain coldness and baldness. Of this we have proof

in the church of St. George's in the East, Ratcliffe Highway, commenced by him in 1715. That of St. Mary Woolnoth, in Lombard Street, is very much better. But it is chiefly as the architect of St. George's, Bloomsbury, that Hawksmoor is entitled to notice. St. Anne's, Limehouse, is another church by him, which deserves more praise than has fallen to its share.

Among his other works were Easton Neston, in Northamptonshire, and a mausoleum at Castle Howard. He was also employed to repair the west front of Westminster Abbey. The south quadrangle and street front of Queen's College, Oxford, have by some been attributed to him, though they are generally supposed to have been the work of Wren. That he did much at All Souls' College, in the same university, is unquestionable. He died in March, 1736, at the age of seventy.

HAWKWEED (*Hieracium*), a genus of perennial plants of the natural order *Compositæ*, or composite family, to be met with in dry, hilly, or woody places, and flowering late in summer or early in autumn. Stems erect and branched. Leaves hairy or rough. The flowers are united in a common calyx, composed of imbricated leaflets. There are above thirty species of *Hieracium* found in Britain.

HAWSE-HOLES, the round holes under a ship's head through which the cables pass. The word hawse is also used to denote the space in front of a ship which lies between her bow and the anchor at which she rides.

HAWTHORN. [*CRATÆGUS*.]

HAWTHORNE, NATHANIEL, a distinguished American author, was born in 1809, at Salem, Massachusetts. He was educated at Bowdoin College, where he graduated in 1825, having for classmates the poet Longfellow and John S. C. Abbot. In 1837 he published a series of papers under the title of 'Twice Told Tales,' of which a second series appeared in 1842. In the following year he married and took up his residence at Concord, where he wrote a charming volume of tales and sketches, entitled 'Mosses from an Old Manse.' In 1846 he was appointed surveyor in the custom-house at Salem, which office he held for only three years. The following books appeared from his pen in succession:—'The Scarlet Letter;' 'The House of the Seven Gables;' 'Grandfather's Chair,' a series of puritan stories for the young; 'A Wonder Book for Boys and Girls;' 'Biographical Stories;' 'Blithedale Romance;' and 'Transformation; or, the Romance of Monte Beni,' which last is regarded by many critics as his best.

Hawthorne was a constant contributor to various reviews and magazines, and in 1852 he executed a task of political value, to himself at least, in the life of Franklin Pierce, who was then a candidate for the presidency. The United States consulship at Liverpool was bestowed upon Hawthorne when his friend was elected president, in which office he remained four years, and left as his latest literary work, 'Our Old Home,' in two volumes, containing admirable criticisms upon English life and society from an American point of view. He died in his native country, May 19, 1864. All his works are written in an exquisitely simple, easy, and graceful style, which, combined with their originality, entitle them to a high place in English literature.

HAY. [*BRECKNOCKSHIRE*.]

HAY is the name given to grass or other plants dried for the purpose of feeding cattle. In the pasture districts of England, the product of a large surface of natural grass land is thus used; but in Scotland the crop consists chiefly of artificial grasses. The plan of making hay varies in different parts, but the following is adopted on the best farms. The grass is cut with a scythe or mowing machine, then shaken and spread out by forks or a tedding machine; towards evening it is raked up into rows, to be spread out again next morning, and again raked into rows, and lastly into heaps or cocks for convenience of carrying. If the weather is favourable, the hay will be ready for the rick on the second or third day. The time required will, however, vary according to the weather, the bulk of the crop, and the quality of the land. Hay usually averages from one to two tons per acre. It should be cut when the grass is in bloom, as it then contains the greatest moisture and nutritive qualities. When left till the seed ripens, it becomes tough and dry, and loses much of its sugar, gum, and gluten. It requires to be carefully made and thoroughly dried before being ricked, as when picked up too soon it becomes over-heated, turns black, and sometimes takes fire. If put together when damp from rain or dew it speedily moulds and spoils. June is the usual month for haymaking in England, and July in Scotland.

HAYDN, JOSEPH, compiler of the 'Dictionary of Dates,' which has passed through numerous editions, and still maintains its reputation as a useful work of reference. He was also the author of 'The Book of Dignities, containing Rolls of official personages of the British Empire, &c. It was a sort of Beatson's Political Index modernized. Mr. Haydn likewise edited the last edition of Lewis' Topographical Dictionaries. He died in 1856; and a short time before his death the government assigned him a small pension of 25*l.* per annum, which is still continued to his widow.

HAYDN, JOSEPH, the renowned musician, was born at Rohrau, in Austria, on the 31st of March, 1732. While quite a child, he learned the violin and singing under a relation, and then practised in the choir of St. Stephen's at Vienna. He gradually studied composition, under circumstances of much privation, and earned a subsistence by his singing; but his soprano voice left him at the age of seventeen. Some pleasant hours with Porpora and Metastasio, a system of giving lessons, a few engagements as an orchestral performer, and an unhappy marriage, brought him down to the year 1761, when, at the age of twenty-nine, he became kapell-meister to Prince Esterhazy, and his privations were, then at an end. In the prince's palace at Eisenstadt, in Hungary, Haydn composed all the great works which he produced prior to the year 1791, and under advantages which few have possessed; he had a full and choice band, living under the same roof with him, at his command every hour in the day.

In 1791 Haydn arrived in London to fulfil an engagement, and produced during that and the following year, at 'Salomon's Concerts,' in the Hanover Square Rooms, six of his 'Twelve Grand Symphonies;' and he also published many canzonets, quartets, sonatas, &c. In 1794, during a second

visit, he produced the remaining six symphonies. His works and performances brought him large profits, as well as honours and compliments from all quarters.

In 1791 Haydn gave to the world his oratorio 'The Creation,' the greatest of his works, though composed in his sixty-fifth year. Two years after this he composed 'The Seasons.' The last productions of his genius were two sets of quartets.

Haydn retired to Vienna on a competency obtained by his professional labours, and there died on the 31st May, 1809. His works are astonishingly numerous, embracing every class. Among them are 116 symphonies, eighty-three violin quartets, sixty piano-forte sonatas, fifteen masses, four oratorios, a grand 'Te Deum,' a 'Stabat Mater,' fourteen Italian and German operas, forty-two duets and canzonets, upwards of 200 concertos and divertissements for particular instruments, &c. Many of these, but not the most valuable, were irretrievably lost in the fire which consumed the palace of his patron at Eisenstädt: the best are out of the reach of danger; they have been printed and reprinted in most of the capitals of Europe. Haydn is universally deemed one of the most original and imaginative of composers.

HAYDON, BENJAMIN ROBERT, an English historical painter of great powers and ability, but more remarkable for the vicissitudes of his life than distinguished for the excellence of his works. He was the son of a bookseller at Plymouth, where he was born, January 23, 1786, and he was educated at Plympton grammar-school. He adopted the profession of a painter contrary to the wishes of his father, who nevertheless allowed his son to visit London and enter as a student in the Royal Academy. Haydon arrived in London in 1804, and in the following year entered the Academy, where he at once formed an intimacy with his fellow-pupils, Wilkie, and Jackson the portrait-painter; his instructors and advisers were Fuseli, Northcote, and Opie. In 1807 he exhibited a picture of 'The Flight into Egypt,' which procured the painter a commission from Lord Mulgrave for his celebrated picture of 'The Murder of Dentatus,' the immediate cause of nearly all the troubles of Haydon's future life, from the dissatisfaction which he felt at the way it was hung in the Academy exhibition of 1809. Though many thought the picture well enough hung, the painter took such a different view of the matter, that he considered it a sufficient cause for a quarrel with and hostility to the Academy, which amounted almost to a monomania, and endured the whole of his life. The picture, which shows great power, is admirably engraved in wood by W. Harvey, Haydon's pupil; the painter described his subject, which is taken from Hooke's 'Roman History,' as 'the celebrated old Roman tribune Dentatus making his last desperate effort against his own soldiers, who attacked and murdered him in a narrow pass.' This was the last picture he exhibited at the Academy; henceforth he established independent exhibitions of his own, and the list shows a considerable series of great and laborious works, but which secured the painter but a very variable success in his speculations, though on the whole he had quite his share of both public and private patronage. His works all suffer from imperfect execution. Haydon was aware of this at

one time, and for a period devoted himself to the study of the Elgin marbles—then recently brought to England—and to portraiture, in order to overcome these defects, wholly without success however. The following are his principal works—In 1812, 'Macbeth;' in 1814, 'The Judgment of Solomon;' in 1820, 'Christ's entry into Jerusalem;' in 1821, 'Christ's agony in the Garden;' in 1823, 'The Raising of Lazarus;' in 1826, 'Pharaoh Dismissing the Israelites,' and 'Venus and Anchises;' in 1827, 'Alexander and Bucephalus,' and 'Fucles;' in 1828, 'The Mock Election in the King's Bench;' in 1830, 'Napoleon at St. Helena;' in 1832, 'Xenophon's first sight of the Sea, in the retreat with the Ten Thousand;' in 1834, 'The Reform Banquet;' in 1835, 'Achilles at the Court of Lycomedes discovering his Sex;' in 1836, 'Samson and Delilah;' in 1838, 'Christ blessing Little Children,' for the Liverpool Blind Asylum; in 1839, 'The Duke at Waterloo;' in 1841, 'The Anti-slavery Convention,' and 'The Maid of Saragossa;' in 1842, 'Curtius leaping into the Gulf;' in 1843, 'The Entry of the Black Prince into London with King John of France as Prisoner' (a cartoon sent to the competition at Westminster hall); in 1844, 'Alexander killing the Lion;' in 1845, 'Uriel and Satan,' and lastly, in 1846, 'The Banishment of Aristides,' and 'Nero watching the Burning of Rome,' illustrating the evils both of democracy and despotism. These two were Haydon's last works, and the disappointment he felt at the failure of their exhibition at the Egyptian Hall was the final weight which crushed him. One of the last entries in his diary is—'Tom Thumb had 12,000 people last week, B. R. Haydon 133½ (the half a little girl). Exquisite taste of the English people.' He was greatly involved in debt, and at last even his energy sunk under his accumulated difficulties, and on the 22nd of June of this year, 1846, he shot himself. One disappointment, from which he is said never to have recovered, was his failure in getting a premium in the Westminster Hall cartoon competition for the decoration of the new Houses of Parliament, an employment he had greatly desired. He was also almost always suffering under pecuniary difficulties, although his receipts were really very large compared with the average income of painters, and he had much liberal help from friends. He passed twice through the insolvent court—in 1823, only two years after his marriage, and in 1836. It is true he sometimes lost by his exhibitions, but he sometimes also gained large sums; as in 1820, when he made nearly 3000*l.* by his picture of 'Christ's entry into Jerusalem.' Latterly, he combined literature with painting; in 1840 he gave some gratuitous lectures on his art at the Ashmolean Museum, Oxford, and from this time frequently delivered these lectures; they have been published, 'Lectures on Painting and Design,' 2 vols. 8vo., London, 1844-46. He published also in 1842, 'Thoughts on the relative value of Fresco and Oil Painting, as applied to the Architectural Decorations of the Houses of Parliament.' As regards Haydon's suicide, he seems to have contemplated on this matter some years before he destroyed himself. In his diary for July 9, 1841, is the following entry—'It may be laid down that self-destruction is the physical mode of relieving a diseased brain, because the first impression on a

brain diseased, or diseased for a time, is the necessity for this horrid crime. There is no doubt of it.' His own brain was diseased in the opinion of Dr. Elliotson and Mr. W. J. Bryant, who made a post-mortem examination of his head. Some have assumed Haydon to have been a martyr to the cause of high art; but his life is a contradiction of this. He had no enemy but himself; he was the victim of the impetuosity and inordinate vanity of his own mind. As a painter, also, he was impulsive and desultory, and neglected all the most essential and common elements of excellence in his execution. He was extremely mannered and disproportioned in his forms; and with the exception of a grand style of design, and a warm and powerful colouring, we miss in his works every requisite of a fine picture. Though he numbered at one time some of our most distinguished painters among his pupils, as Sir Charles Eastlake, Sir Edwin Landseer, and George Lance the fruit-painter, he served rather as a warning to them than otherwise, showing them what to avoid rather than what to imitate; and his efforts have remained wholly without influence on the art of his time, though he was egotistical enough to consider nearly all progress to have proceeded from himself, and identified the fate of British art with that of his own efforts.

HAYESINE, or borate of lime ($\text{Ca O, B}_2 \text{O}_3 + 6 \text{H, O}$), a substance named after the mineralogist Hayes. It is found in Peru, in rounded nodules about the size of an orange. The Peruvian government prohibits its exportation; though, by secret means, considerable quantities reach this country, where it sells at about 30*l.* per ton. It is used in the arts, as a source of boracic acid in the production of borate of soda, employed in pottery and glass-making.

HAYLEY, WILLIAM, was born at Chichester in 1745, and studied at Trinity Hall, Cambridge, intending to practise as a barrister. Finding the law not to his taste, he settled on his patrimonial estate of Earham, in Sussex, in 1774. Hayley died November 20, 1820. Of his numerous poetic works, the 'Triumph of Temper,' 1781, has been the most popular. The 'Essay on Painting,' 1778, and 'Essay on History,' 1781, rank among his best productions. We may add, as the most important of his other numerous works, the 'Essay on Epic Poetry,' 1782; 'Life and Poetical Works of Milton,' 1794-99; 'Essay on Sculpture,' 1800, addressed to his friend Flaxman; 'Life of Cowper,' 1802.

HAYMAN, FRANCIS, R.A., was born at Exeter about the commencement of the eighteenth century. He was the scholar of Robert Brown, and was in early life much employed as a scene-painter by Fleetwood, the proprietor of Drury Lane theatre, and by Tyers, the proprietor of Vauxhall. He painted some historical pictures, and also made many designs for booksellers, the best of which are the illustrations to Sir Thomas Hanmer's 'Shakspeare.' He was the first librarian to the Royal Academy. He died in 1776.

HAYNAU, JULIUS JAKOB, BARON VON, was born at Cassel in 1786, entered the Austrian army in 1801, and rose through the various military grades until in 1844 he became field-marshal lieutenant. In the Italian wars of 1848-49 he was remarkable alike for military talent and for merciless

severity. When the inhabitants of Brescia rose in arms to second Charles Albert in his final struggle, Haynau marched rapidly from Perugia, and invested the town, March 30, 1849. The defence was gallant, and the punishment terrible; the whole place was given up to fire and sword; nor did Haynau shrink from owning, in his official report, that the atrocities which shocked all Europe had been committed by his order. Soon afterwards the emperor summoned him to take supreme command of the Austrian forces in Hungary. He entered Raab on June 28, occupied Szegeidin on August 2, and in another week entered Temeswar. Until June, 1850, Haynau exercised an almost absolute sway in Hungary, and his rule was a veritable 'Reign of Terror;' his atrocious treatment of the defeated Hungarians, and especially his alleged flogging of women, excited the hatred and detestation of Europe. He visited London in 1850, when the workmen at Barclay & Perkins' brewery assaulted and mobbed him, and he barely escaped with life. Few men blamed them very severely, and the British government declined to give any satisfaction for the assault. Haynau wandered over the continent, and narrowly escaped another beating at Brussels. At Paris the police protected him, but he was hated and shunned as an outcast. Returning to Germany, he died in the autumn of 1853.

HAYTI. [HISPANIOLA.]

HAZEBROUCK. [NORD.]

HAZEL. [CORYLUS; FILBERT.]

HAZLITT, WILLIAM, the son of a Unitarian minister of the same name, was born at Maidstone on the 10th of April, 1778. When he was five years old, his father transferred the scene of his ministerial exertions to America, and remained with his family in the United States for two years. On his return to England, the father became pastor of the Presbyterian congregation at Wem in Shropshire; and it is here that the work of Hazlitt's education was commenced. At the age of nine he was put to a day-school at Wem. In 1793 Hazlitt was entered as a student of the Unitarian College at Hackney, in order to be educated for his father's profession. But for this profession he had no liking; and, having from a very early age shown a taste for drawing, it was determined that he should follow the profession of a painter. He commenced with great ardour and assiduity, cultivating metaphysics in his intervals of leisure. In 1802 he visited Paris for the purpose of studying the paintings in the Louvre; and on his return to England in the next year, he made a professional tour, and painted a considerable number of portraits; but he did not persevere. His notion of success was so exalted, and his fastidiousness so great, that he could never satisfy himself, and he determined on again changing his plans.

He now proceeded, in the autumn of 1803, to the metropolis to start as a literary adventurer. He commenced his almost endless series of publications with the essay on the 'Principles of Human Action,' which was published anonymously in 1805, and was followed up quickly by other works. In 1808 he married a Miss Stoddart, the sister of Dr. (afterwards Sir John) Stoddart, and after his marriage retired into Wiltshire, where he continued without intermission his literary pursuits. In 1811 he

returned to London, and we find his residence in a house in York Street, Westminster, which had been once inhabited by Milton, and which then belonged to Bentham.

In 1813 Hazlitt delivered a course of lectures at the Russell Institution, on the history of English philosophy; and subsequently on the English poets generally, the comic poets, and the poets of the age of Elizabeth, in separate courses, at the Surrey Institution. He acted for a short time also as reporter to the *Morning Chronicle*, and, after giving it up, still wrote occasionally in that paper, and also in the *Examiner*. He was also, in the latter part of his life, a contributor to the *Edinburgh Review*, and to some smaller magazines. His life was indeed one unintermitting course of literary exertion; and his labours brought him in a considerable income, which, however, his imprudence always quickly dissipated.

In 1822 he was divorced from his wife, and two years afterwards he married a second time. He died on the 18th of September, 1830, of cholera, and was buried in the churchyard of St. Anne's, Soho, London.

Hazlitt's principal works, besides those which have been already mentioned, are the 'Round Table,' in which he was assisted by Mr. Leigh Hunt; the 'Table-talk;' the 'Plain Speaker;' the 'Characters of Shakspeare's Plays;' the 'Spirit of the Age;' his 'Political Essays,' which are collected from different newspapers and magazines, and published in one volume, with a preface by Hone; and the 'Life of Napoleon,' which Hazlitt himself looked upon as his great work, and which was his last.

The principal merits of Hazlitt as a writer are force and ingenuity of illustration, strength, terseness, and vivacity. After his death, two volumes of his 'Literary Remains' were published by his son, with a short memoir, which shows much taste and good feeling.

HEAD. [BRAIN; SKELETON.]

HEAD BOROUGH, the former name of the high constable, or head of a borough. The term is also used in Scotland to denote the borough in which the sheriff holds his court.

HEAD, INJURIES OF THE. From the many peculiar and important features which they present, injuries of the head have properly received a separate consideration in all systems of surgery; for not only is the brain so essential to life that even its least injury must be regarded as serious, but the parts around and guarding it have many peculiarities. The injuries of the head are best considered as they affect the parts inclosing the brain or the brain itself.

In mere bruises of the scalp two circumstances are worthy of notice. A vessel of some size may be burst without the skin over it being wounded, in which case a most copious effusion of blood takes place, raising up the scalp from the skull, and producing rapid swelling of the whole of the upper part of the head. It needs, however, no particular treatment; no incision should be made into it, for if cold wet cloths be diligently applied, the blood will be again rapidly absorbed.

A common superficial wound of the scalp needs no particular treatment. It should be closed with sticking-plaster after the hair around it has been

shaved off, and it should be kept cool with pledgets of lint dipped in cold water and covered with oiled silk; but to guard against mischief to the adjacent parts, the patient should avoid all stimuli, and all exertion of either body or mind, till it is completely well.

One of the most common sequels to injuries of the scalp is erysipelas of the head and face. It generally occurs in persons of an unhealthy habit, in hard drinkers, and in the full and plethoric. It commences about the third or fourth day after the injury. There is general fever, and the head and face feel very hot, and become red and swollen, appearances which increase, and, after a day or two, are accompanied with an eruption of small blisters, full of yellow fluid. There is no pain on touching the parts; but by the great swelling the eyes are often closed, and the features almost obliterated. Active reducing measures should, as a general rule, be early employed, and continued, if the disease does not yield, as far as the patient's strength will permit; and purgatives, with small doses of mercury, may be given.

Another affection which sometimes follows injuries (and especially punctured wounds) of the external coverings of the skull, is inflammation and consequent extensive suppuration in the loose tissue connecting the tendon of the muscle covering the top of the head with the pericranium. When this affection is suspected to be coming on, leeches should be put on the head in large numbers about the wound, and cold diligently applied; but if matter should form, one or more free incisions should be made through the scalp to let it out, and the part afterwards treated like a common abscess.

In cases in which the bone has been exposed, the same general and local treatment should be employed.

When the bone itself is injured, no active treatment should ever be adopted, unless there are evident signs that the brain is suffering from compression or other remediable injury.

The vessels of the dura mater may be ruptured by the jar from a blow which does not even break the skin. The blood that flows from them, accumulating between the dura mater and the skull, produces compression of the brain. The only hope in these cases is to bleed the patient largely, to check the flow of blood in the head, and, if that be not evidently beneficial, to apply the trephine wherever it is most probable that the blood may be found and removed.

Instead of blood, purulent matter may collect between the dura mater and skull, and produce equally fatal results. This is indicated by the patient (usually some considerable time after the accident) complaining of headache, restlessness, and extreme languor; he has frequent irregular shiverings, his pulse is quick and hard, and he cannot sleep; if unrelieved by treatment, all these symptoms increase, and are shortly followed by delirium, convulsions, insensibility, or paralysis, which are no distant precursors of death. A tumour forms on the part struck, and if this be opened, the pericranium will be found detached to some extent from the skull.

The brain itself may suffer injury either from blood effused in it by rupture of its vessels, from compression by fractured portions of bone being forced down

upon it, from wounds, from concussion, or from inflammation and its various effects following any of these injuries. The first does not differ in its symptoms from the cases of common apoplexy with effusion of blood [APOPLEXY], and admits of no mechanical treatment. The second class comprehends the most important injuries of the head: those of 'fracture with depression,' as they are called, and those which occasionally happen in children, in which the skull is indented without being broken. The symptoms of such an injury are insensibility, generally in direct proportion to the degree of pressure; the breathing is slow, laboured, and snoring, and at every expiration the cheeks are puffed out and elevated; the pulse is slow and irregular; the pupil widely dilated and insensible to light; the patient neither feels nor moves, and lies as if in a fatal state of apoplexy. The evident and indeed the only mode of affording relief is to remove the pressure from the brain, by exposing the fractured part of the skull by enlarging the wound in the scalp, or making a fresh one, and taking away or elevating all the portions of bone that are depressed. Such cases, and all others in which compression cannot be mechanically relieved, can only be treated like common apoplexy, by bleeding the patient, by cold sedulously applied, and by rigorous reducing measures.

The immediate consequences of wounds of the brain vary greatly, and indeed unaccountably: in some cases a very slight injury is rapidly fatal, as in those (of which many are now recorded) in which a pointed instrument has passed in through the orbit, and produced almost instant death; whilst in others, severe and extensive injuries, as from gun-shots, have been followed by serious symptoms at only a late period from their reception.

The last injury of the brain that needs particular notice is that called concussion or commotion. In its slightest degree it is merely a stunning, from which perfect recovery takes place in a few minutes; when most severe, it is rapidly fatal; but, even then, a post-mortem examination discovers no alteration whatever in the structure of the brain. One of the most interesting points in surgery is the diagnosis of concussion from compression of the brain. As the latter seldom occurs without the former (for of course a blow which would fracture or indent the skull would violently shake the brain), compression has the symptoms of concussion, with the addition of some of the most severe which we have already mentioned. In concussion the patient is insensible only to slight impressions, for if he be loudly called to, he will wake up, answer a word or two, perhaps even rationally, and then relapse into the same state. If he be severely pinched or otherwise irritated, he will withdraw the part so injured: he occasionally moves his limbs; he appears, in short, as if in a sound heavy sleep like that of a drunken man. The breathing is not stertorous, but generally quite natural; the pupil is contracted and irritable; the pulse is sometimes unaffected, but in severe cases small and weak; there is nausea or vomiting, and the extremities feel cold. If the case is about to terminate fatally, the whole body grows rapidly cold, the pulse becomes irregular and weaker, the breathing short and interrupted, and the insensibility increases. In treating cases of concussion much caution is needed:

it has not appeared that bleeding, which is the remedy popularly expected for all such accidents, has at all diminished its primary symptoms, nor has the contrary treatment by stimulants been more successful. The patient, while suffering from the immediate stunning consequences of the blow, should merely be kept quite warm in bed, and carefully watched; if the pulse grow weaker, the extremities colder, and the other symptoms of sinking seem increasing, stimulants are first called for, and should be given till he is completely roused to his former state; but if, instead of being depressed, he remain stationary, no active means of any kind should be employed.

HEAD, SIR GEORGE, deputy-knight marshal to her Majesty, was born at Higham, in Kent, in 1782, and is known as the author of various works of some literary repute; among others, his account of 'Forest Scenery and Incidents in the Wilds of North America, being a Diary of a Winter's Route from Halifax to the Canadas, during Five Months' Residence in the Woods, and the Borders of Lakes Huron and Simese.' Sir George had been engaged to superintend the commissariat duties of the British Settlement in North America for many years; and while on the Halifax station, engaged in that capacity, the above Diary was made, and published in 1829. Encouraged by the success which accompanied this work, he brought out his 'Home Tour through the Manufacturing Districts of England in the Summer of 1835;' his 'Home Tour through various Parts of the United Kingdom;' 'Memoirs of an Assistant Commissary-General;' and 'Rome, a Tour of Many Days.' He was also the translator of Cardinal Pacea's 'Historical Memoirs,' and the 'Metamorphoses of Apuleius,' which were published in 1850 and 1851. He was likewise an extensive contributor to the pages of the *Quarterly Review*; while his brother, Sir Francis Head, was the author of a very popular work known as the 'Bubbles of Nassau.' Sir George received the honour of knighthood in 1831; and died in 1855.

HEADBOROW, a term applied by the Saxons to the head of the frank-pledge in boroughs. He was the chief of the ten pledges, as the other nine, being inferior pledges, were designated *handborows*.

HEALTH, BILL OF, in Shipping, is the certificate of a consul as to the health of a crew when the ship has come from a suspected port. The names given to the documents representing the various degrees of health are a clean bill, a suspected bill, and a foul bill.

Bill of Health, in the law of Scotland, is an application made to the Prison Board by a prisoner to be allowed to live away from the prison, of course under surveillance, on account of ill-health. This is sometimes allowed both in England and Scotland, but it is only in the latter country that the petition is called a bill of health.

HEALTH, PUBLIC. [PUBLIC HEALTH.]

HEANOR. [DERBYSHIRE.]

HEARING. [EAR.]

HEARNE, THOMAS, an eminent English antiquary, was born at White Waltham, in Berkshire, in 1678, where his father was the parish clerk. In 1692, under the patronage of Francis Cherry, Esq., of that place, with whom he had till then lived as a menial servant, he was placed at the free school of

Bray, and subsequently, in 1695, at that gentleman's expense, was entered of Edmund Hall, Oxford. He became B.A. in 1699. In 1701 he received his first employ in the Bodleian Library. He was afterwards made janitor of the library, and in 1712 succeeded to the place of second librarian. In January, 1715, he was elected architypographus and esquire bedel of civil law in the University, which post he held with his under-librarianship till the month of November following, when he resigned the bedel's place, and soon afterwards his post in the Bodleian Library, on account of the oaths to the government, which he could not conscientiously take. He continued a non-juror to the last, much at the expense of his worldly interest. He died June 10, 1735.

Hearne's publications were almost exclusively printed by subscription at Oxford, and are very numerous. Among the most valuable are—an edition of Livy, 6 vols. 8vo., 1708; the 'Life of Alfred the Great,' from Sir John Spelman's MS. in the Bodleian Library, 8vo., 1710; Leland's 'Itinerary,' 9 vols. 8vo., 1710; Leland's 'Collectanea,' 6 vols. 8vo., 1715; Camden's 'Annals,' in Latin, 3 vols. 8vo., 1717; 'History and Antiquities of Glastonbury,' 8vo., 1622; 'Robert of Gloucester's Chronicle,' 2 vols. 8vo., 1724; 'Peter Langtoft's Chronicle,' 2 vols. 8vo., 1725.

HEARSAY. [EVIDENCE.]

HEARSE, a funeral carriage in or on which a corpse is borne to its last resting-place. In England it is usually a closed carriage, decorated with plumes or feathers on the top and black drapery at the sides. On the occasion of public funerals, and generally on the continent, the hearse is an open car on which is placed a bier with the coffin.

HEART is the central organ of the circulation, and by its alternate contractions and dilatations is one of the principal powers by which the blood is moved through the bodies of the higher animals.

The simplest mode by which a distribution of nutritive fluid is effected, is by means of ramifications proceeding from the stomach or intestinal canal to various parts of the body, which occurs in the polyps, infusoria, intestinal worms, echini, medusæ, and other zoophytes. In all these the digestive canal and the circulating system form but one apparatus; the food, which in the higher animals requires a complicated process of assimilation before it is fitted to move with the blood, is in them already adapted for nutrition. In most of them currents can be seen passing in opposite directions along the canals opening into the digestive cavity, exactly like those well known to exist in the stems of charæ, and probably produced by the motion of ciliæ which line the tubes, but are too minute to be discerned even with the microscope.

In the annelida the circulation is carried on by means of two large vessels which alternately contract and expand, and thus carry the circulating fluid to all parts of the body. The first indication of an organ like the heart is seen in insects, which have a large vessel running along the back, divided by numerous constrictions into a series of communicating cavities, between which there are lateral openings through which the blood is received, and which are guarded by valves to prevent the blood from flowing out. Through this, which is commonly called the dorsal

artery, but which may rather be regarded as a series of ventricles, the blood passes from behind forwards, diverging into small streams, one of which flows to each of the antennæ, feet, &c. No distinct vessels can be detected in which these minor currents may run; they seem simply to pass through the various tissues, and, having arrived at their destinations, to form there into arches, and return and empty themselves into abdominal vessels, which may be regarded as veins, and through which the blood flowing from before backwards is returned into the dorsal artery through the communications which exist between them at the posterior part. This is also the plan of the circulating system which with various modifications prevails in the arachnida and the lower crustacea.

The simplest kind of a heart, forming a defined cavity, is found in some of the larger crustacea.

In most of the mollusca the blood flowing through the branchial veins, instead of being poured directly into the ventricle, is received first into an auricle, presenting the first instance of a heart with more than one cavity. In most of the gasteropoda and pteropoda the auricle is single; in the bivalves the auricle is double.

Among vertebrate animals the simplest form of heart is found in fish. They have a single auricle which receives the blood from the trunks of the veins of the whole body, and communicates with a single ventricle, which forces the blood into an arterial trunk with a contractile bulb. From this trunk all the branchial arteries arise, and, passing on each side in arches to the gills, divide there into capillary branches. The blood thus aerated passes on, and the arches again unite into a common trunk the true aorta, which runs along the under surface of the spine, and sends the blood to all parts of the body. From these it collects again into the systemic veins, by which it is carried back to the auricle. The same type of formation is found in the reptiles which have gills.

In the air-breathing reptiles there is a single ventricle from which arises a single aortic trunk, from which proceed two pulmonary arteries, conveying that part of the blood which is to undergo respiration to the lungs, whence it is returned by pulmonary veins. From the same aortic trunk four other arteries arise, two of which, forming arches, unite to form the dorsal aorta, while the two uppermost are distributed to the head and upper extremities. From the terminations of these arteries in all parts of the body the blood is collected into large venous trunks, which open into a double auricle, from which the aerated blood from the lungs and the impure blood from the system pass separately into the common ventricle, in which they are intimately mixed.

Man, mammalia, and birds have a double circulation, to which some of the forms just described make very close approximations.

The heart of man may be taken as the type of this circulation. It is of a somewhat conical form, having its base directed backwards towards the spine, and its point forwards, downwards, and to the left side, so that at each contraction it may be felt striking between the fifth and sixth ribs, about four inches from the middle line. It rests upon the diaphragm, or muscular partition between the chest

and abdomen, and the surface upon which it lies is much flattened. It is firmly attached to the diaphragm at its right side, and behind by the inferior cava, which passes through that muscle, and above and behind it is fixed, though more loosely, to the upper and back part of the chest by the rest of its great vessels, which there pass out of the pericardium, and are united to the surrounding cellular tissue and organs. Everywhere else it is quite free and movable, though the range of its motions is limited by the pericardium, or membranous bag in which it is contained, and which closely surrounds it at all times.

To examine the interior of the heart, it should be removed from the pericardium, and an incision should be made into the front of the right or front auricle, so that an angular flap may be cut out of its walls, and the whole view of the back part and sides of its interior may be exposed. There will then be seen, behind and to the right side, two large apertures; the upper leading to the vena cava superior, through which all the blood is returned from the head and upper extremities, and the lower leading to the vena cava inferior, by which all the blood is conveyed from the abdomen and lower extremities. These apertures will be seen to be surrounded by a few muscular fibres continuous with those of the auricle itself, and that of the inferior cava is partially guarded by a thin semi-lunar membranous fold, called the Eustachian valve, varying much in size, and often much torn. The left side of the cavity, on the partition which separates it from that of the right auricle, presents an oval depression (the fossa ovalis) surrounded by an elevated border, indicating the situation of the foramen ovale, through which, during the foetal state, the blood, which was prevented by the Eustachian valve from passing into the ventricle, was conveyed directly from the right into the left auricle, and thence into the left ventricle. Lastly, at the anterior and left angle of the cavity another and the largest aperture is seen, which leads into the right ventricle, and has attached to its sides a membranous curtain, by which it is occasionally closed, and which is called the tricuspid valve.

Proceeding in the course of the circulation, a cut should be made from the right auricle through the aperture leading from it into the right ventricle, and along the front of the heart nearly to its apex, and then another from the end of the first upwards into the pulmonary artery, as it arises from the front and upper part of the ventricle. By raising the portion thus cut out, a complete view of the cavity of the right or pulmonary ventricle, and of its communication with the auricle, will be seen. The cavity of the right ventricle has a somewhat conical form, with its base uppermost, that part of its walls which is formed by the septum projecting somewhat into it. Its walls are rendered extremely irregular by prominent bands of muscular fibre. Here and there stand out short columns of muscle projecting into the interior, and pointing towards the right auricle; these are called columnæ carneæ, and they have attached to their summits fine tendinous cords (chordæ tendineæ), which pass thence to be attached to the edges of the curtain-like membrane (the tricuspid valve) which guards the orifice between the auricle and ventricle. This orifice is of a broadly oval form, surrounded by a ring of firm dense tissue,

to the whole interior circumference of which is attached the fold of membrane, strengthened by tendinous fibres, forming the valve.

From the front and upper part of the ventricle a smooth short passage leads to the origin of the pulmonary artery, which is attached firmly to the dense ring to which many of the muscular fibres of the ventricle are affixed. At their union, and at the very orifice of the pulmonary artery, three little valves (the semi-lunar, sigmoid, or pulmonary valves) are seen, of a semi-lunar form, attached by the whole length of their convex edges to the walls of the artery, and hanging loosely in it with their free festooned edges directed upwards, inclosing behind them three small spaces, where the artery bulges somewhat outwards. These valves completely close the orifice of the artery inwards, so as to prevent any fluid from passing into the ventricle.

The left posterior or aortic ventricle and auricle differ in no important particular from the right. The walls of both cavities on the left side and all the parts contained in them are thicker and stronger than those on the right; the orifice between them is guarded by a valve which has only two principal divisions, and is therefore called the mitral valve. The aorta proceeds upwards, and to the right side, then arches backwards and to the left, and, turning over the main air-tube of the left lung, passes down along the spine, at the lower part of which it divides into two large arteries (the common iliaes) which supply the pelvis and lower extremities. From the upper part of its arch it gives off the main trunks of the head and upper extremities in three large trunks—that most to the right, called arteria innominata, is the common trunk which divides into the right carotid for the right side of the head, and the right subclavian for the right arm and side of the neck and chest. Next to it is the left carotid, and next the left subclavian, of which the distribution is similar to that of those on the right side.

During life, the blood returning from the whole body by the veins which unite to form the two venæ cavæ enters the right auricle and gradually distends it, at the same time that the blood returning from the lungs by the pulmonary veins enters the left auricle and distends it. When completely filled, a kind of vermicular motion is seen commencing at the point of each auricle, which is rapidly propagated along their walls, and simultaneously empties the contents of the one into the right, and of the other into the left ventricle. The ventricles are no sooner completely filled than they contract suddenly and with much greater force than the auricles, and propel the blood into the pulmonary artery and aorta. From the aorta the blood is propelled into the arteries, through which it is distributed to all the body, and returned by the veins; but the veins of the intestinal canal and the organs connected with it unite into a large trunk, the vena portæ, which, instead of at once entering the heart with the others, passes into the liver, and there again divides into minute capillary vessels, from which the bile is secreted, and which pass into the ultimate divisions of a series of hepatic veins, which collect into three or four large trunks which open into the vena cava inferior just before it passes through the diaphragm to enter the right auricle.

The accompanying figure represents a section of the heart and lungs. The line A crosses the left lung and enters the left side of the heart. The line B passes the right lung to the right side of the heart.

Harvey considered the heart to be the sole agent by which the circulation is effected, but it is certain that several other agents exercise auxiliary powers. That the heart has, however, an influence on all parts of the circulation, is quite evident. In the larger arteries its effect is seen in the increase of the current which it has set in motion, in exact coincidence with the contraction of the ventricles; in the smaller ones, by the same increase at a scarcely appreciable interval; in the capillaries, by the occasional pulsatile motion which may be seen in them, when, after an animal has been largely bled, its transparent parts are examined with the microscope, and this though the heart is acting very weakly. Lastly, in the veins we find its influence

Heart and Lungs.

still exerted; for if the main artery and vein in a limb be exposed and isolated, and the latter be wounded, the flow of blood from the orifice may be exactly regulated by compressing the artery, that is, by preventing, to a greater or less extent, the blood from flowing to the vein with the impulse given to it by the heart. It appears also that, in addition to propelling the blood, the heart during its expansions draws up the blood, so that it acts both as a sucking and a forcing pump.

From the heart the blood is poured into the arteries, a series of ramifying tubes through which the current is distributed, divided into a gradually increasing number of streams, which progressively diminish in size, till it arrives at a network of the most minute canals, the capillaries.

The chief property of the arteries by which they affect the circulation is their extreme elasticity. It is by this that when dilated they contract on the

blood that had been forced into them, and propel it in every direction, and that when elongated they again shorten, and that when empty they remain open and tubular. The chief effect of the action of this elasticity is the gradual conversion of the jetting pulsatile motion, which the blood receives from the forcible and successive contractions of the ventricle, into an even and steady current.

We have said that the arteries are dilated slightly by each column of blood poured out by the ventricles: from this arises their *pulse*, which may be said to be owing to the dilatation of the arteries produced by the wave which is propagated along the column of blood contained in them. The frequency of the pulse depends entirely on the number of contractions of the left ventricle in a certain time; and hence the varieties of frequent, slow, irregular, intermitting pulses are entirely referrible to the heart. The size and degree of contraction of the artery produces the fullness or smallness, the hardness or softness, and all the other characters which are determined by the touch rather than by mere counting.

From the fact that the great chemical change by which heat is developed in the animal system takes place in the capillaries, it follows that their influence on the circulation is very considerable. They form a dense network of extremely minute tubes, in which the arteries seem to terminate and the veins to arise, for their delicacy prevents the possibility of discovering any such structure as could decide to which set of vessels they belong; and indeed it is only by observing that the currents of blood-globules pass in regular directions that we can prove that they are canals with definite membranous walls. When the circulation is examined in the web of the foot of a frog, or in the transparent parts of other animals, as the fins, tails, or lungs

of fish, frogs, lizards, &c., we see a number of minute corpuscles coursing along in little streams, in some parts in a confused multitude, as in the vessels which are sufficiently large to admit several to pass together, at others in only a single line, where the vessel is but little larger than the corpuscle itself. The currents run generally in the same direction in the same vessels, all tending to a larger branch, which may be regarded as the commencement of a vein, and setting out from the minutest termination of the artery. The capillaries are the most delicate of all organic tissues, measuring from 1-2000 to 1-5000 of an inch in diameter; they exist in all tissues of the body, varying in arrangement only in the greater or less closeness of the network which they form, and of which the meshes are in some organs so fine as not to exceed in width the diameter of the capillaries themselves, as is the case in the iris and lungs. It is through

these vessels that all the important processes of secretion, nutrition, and absorption are effected.

These corpuscles are elongated-oval in birds and larger than in mammals. They are larger still in reptiles and in fishes, and largest in the amphibia. The blood of fishes leads the naturalist to a yet farther distinction with regard to that great class of animals. The blood corpuscles of bony fishes are roundish-oval, those of cartilaginous fishes are much larger, more distinctly oval, and bear a considerable resemblance to those of frogs. There is no perceptible difference in the general appearance of the blood discs in the different families of man.

The influence of the minutest arteries and veins, and of the capillaries, on the circulation, is best seen in the phenomena of local action, as inflammation, blushing, turgescence, &c. If the web of a frog's foot placed in a microscope be irritated, the capillaries are seen slowly contracting, so as sometimes to prevent the flow of blood through them; and if the stimulus be so great as to produce inflammation,

then they dilate, and a larger number of globules is seen passing along them with great rapidity. The same may be seen in the human eye, when particles of dust get into it. On a larger scale, one sees after a wound or other injury the parts around grow redder, and swell from the afflux of blood to its capillaries; and if the inflammation arise in a part which can be compared with another similar one, as in the hand, one feels that the pulse is fuller and stronger on the injured than on the sound side, indicating that a larger quantity of blood is passing through it. A still more evident accumulation of blood is shown in blushing, in which, from a mental impression, in an instant all the minute vessels of the face, neck, head, &c., become distended with blood. The paleness of fear is produced by the opposite condition; and we have other cases in which a decrease of the quantity of blood in a part is seen in the deficient nutrition and shrinking of parts which have become useless, as in the gills of tadpoles, the horns of deer, &c. All these circumstances are clearly sufficient to prove

Corpuscles of Human Blood.

Corpuscles of Blood of Birds.

Corpuscles of Blood of Fishes and Amphibia.

that, independent of any influence extending from the heart or arteries, there is in the very minute vessels of all parts a power by which the supply of blood passing through them may be either increased or diminished.

Following the course of the circulation, we come now to the veins, which may be regarded as the most passive of the parts engaged in it, though they are constructed so as to permit many important external agencies to act upon the motion of the blood. In addition to other peculiarities of structure, the veins have valves, very similar to those at the origins of the arteries, which are arranged in pairs, or in threes, at different distances, in the course of nearly all those veins in which the blood has to rise against the power of gravitation. Their simple use is evident: the blood, returning slowly through the capillaries, and much of the force of the heart being expended in propelling it so far, would be apt to retrograde, or remain stationary, if the weight of the whole column in the veins bore down upon the arteries, and through them on the heart. As soon, however, as a portion is raised into a vein, when it tends to return to the arteries it forces down the valves, which close the canal of the vein and support the blood above them, till another portion rising sends it onwards. Thus, while they permit the blood to pass without obstacle towards the heart, they entirely prevent it from retrograding; and if it were station-

ary, the column of blood would be like a stream branching out and divided by a number of closed locks, in which the portion of fluid between any two is prevented from exercising any influence on the portions adjacent to it.

HEART, DISEASES OF THE, may be divided into those which occur in its investing membrane, those which affect it as a whole, and those of its various parts.

1. *Pericarditis: Inflammation of the Pericardium*, resembles much, in its pathological conditions, inflammation of other serous membranes, and is induced by similar causes, as exposure to damp and cold. It of course presents peculiar symptoms, arising from the situation and nature of the individual organ; thus the patient will complain of tenderness over the region of the heart, amounting, when pressure is made, to acute lancinating pain, which prevents him from lying on the left side, and is much increased by drawing deep inspirations, or coughing, this latter symptom frequently depending on the pleura being involved in the inflammatory attack. This pain, however, is not always so severe; frequently only a sense of oppression is felt. The pulsations of the heart are frequent, sometimes regular, but at other times intermittent, and so strong as to constitute palpitations; but still, if much effusion has taken place into the pericardium, the hand when applied to the chest will have difficulty in perceiving them. The præcordial portion

of the thorax is often bulged out by the forcible action of the heart and the quantity of fluid effused into the cavity of the pericardium. This effusion varies much in quantity and consistence at different periods of the disease: thus in many cases only a little bloody serum will be found; in others, pus in large quantities, coagulated lymph, bands of fibrinous matter uniting the two layers of the serous membrane, and even cartilaginous or osseous deposits. The dull sound discovered by percussion in the præcordial region of a person in health is always, in this disease, increased in proportion to the quantity of fluid in the pericardium, and, in proportion as this fluid becomes organized, sounds will be heard by the application of the stethoscope, and often of the unassisted ear, varying in their nature according to the state of the organizing process, and resembling at one time the creaking of new leather, at another the rubbing together of paper or parchment, the noise made by a file, &c. Other sounds also are frequently heard, which depend upon the disease being accompanied by lesions within the heart itself. This disease frequently accompanies acute rheumatism, and forms one of the worst features of that very common affection.

2. Serum is sometimes found in the pericardium independent of inflammation, constituting the disease known as *hydro-pericardium*.

3. *Displacement*.—The heart is not always found in its usual situation at the time of birth, there being cases on record where it occupied the right instead of the left side of the chest, the other organs of the body presenting at the same time a relative change of position without any disturbance of their functions. It has also been found pushed out of the left into the right side of the chest by tumours, or, what is more common, by extensive effusion of fluid into the pleura of the left side of the chest.

4. *Carditis: Inflammation of the Heart*.—The proper muscular structure of the heart is not free from the attacks of inflammation; but where this disease exists there will also be found traces of it in the pericardium, or in the lining membrane of the heart, or in both; and we cannot point out symptoms of the one distinct from those of the other disease: the treatment, consequently, is similar in both.

5. *Hypertrophy of the Heart*.—Independently of any morbid process existing in itself, the muscular structure of the heart is often greatly increased in bulk, as if the nutritive process were too active in proportion to the absorbent, and new matter were deposited more rapidly than the old could be removed. From the peculiar nature of the functions of the heart, this disease becomes very important, and its effects not less dangerous than manifold. It is usually divided into three kinds: namely, simple hypertrophy, the least common, in which the parietes are thickened without any change of capacity in the cavity; eccentric or aneurismal hypertrophy, the form most frequently met with, in which the parietes are thickened and the inclosed cavity or cavities proportionally enlarged; and concentric hypertrophy, where the cavity is diminished in proportion to the thickness of the parietes. Any one of these kinds of hypertrophy may affect the parietes of either cavity of the heart, or the whole organ. The extent to which this increase of size may proceed is enormous;

hearts have been found weighing upwards of twenty ounces, whereas the average weight of a healthy heart is from seven to nine ounces. In hypertrophy the chest is often bulged out towards the left side, the sound produced by percussion more dull than in the healthy state, and the pulsations very strong; indeed the bed-clothes are often visibly raised, and the head or hand of the observer, when applied to the chest, forcibly repulsed, yet the pulsations are for the most part regular, unless palpitations be induced by over-exertion. The sounds perceived by auscultation are louder than natural. Hypertrophy of the left ventricle of the heart sometimes brings on apoplexy and hæmorrhages.

This is a disease in which great perseverance is required on the part of the patient and the practitioner, but with proper care it frequently admits of much alleviation. Rest, abstinence, sedative medicines, and more or less depletion, according to the circumstances of the case, are the most efficacious plan of treatment.

6. *Atrophy of the Heart* has also been observed accompanying a state of general debility of the system.

7. *Dilatation of the Heart*.—It has been shown that the heart may be increased or diminished in substance, or may be hypertrophied or atrophied. The whole substance of the heart, or either of its cavities singly, or the orifices of these cavities, may be dilated, the solid parietes being merely extended, without any increase of substance, and the contained cavities proportionally enlarged. As in hypertrophy so in this disease, according to its extent the shape of the heart will be much changed. The muscular parietes being thinned and feeble, the circulation of the blood will not be carried on with vigour, and the patient will be weak and unfit for exertion, easily exhausted by small losses of blood, and sometimes carried off by what under ordinary circumstances would be deemed a trifling hæmorrhage. Excessive exertions and strong passions seem to be exciting causes of this disease, and from the influence of these causes the patient should be sedulously guarded, and, at the same time, every remedy must be adopted which may contribute to equalize the circulation.

8. *Endocarditis: Inflammation of the interior lining membrane of the Heart*.—This disease is not very frequently met with uncombined with some other inflammatory disease; rheumatism, pericarditis, carditis, or inflammation of the internal coat of some of the veins will be usually found, if not to accompany, at least to have preceded it.

The principal symptoms of endocarditis are more or less fever and anxiety; some bulging of the præcordial region, if accompanied by pericarditis; an extension of the dull sound heard on percussion in the healthy state; the pulsations of the heart unusually strong, and sometimes very rapid and intermittent, repulsing the hand when applied to the chest, and producing a peculiar vibratory sensation. Upon auscultation the bellows' sound will be heard, masking one or both of the normal sounds.

The causes of this serious malady are similar to the causes of pericarditis, and the treatment must be actively antiphlogistic.

9. *Disease of the Valves*.—The internal lining membrane of the heart is often thickened, especially

at the valves; and after repeated attacks, or a long chronic form of endocarditis, the valves will not merely be thickened, but will become the seat of a variety of warty excrescences, or even cartilaginous and osseous formations of considerable size, extending into the cavities of the heart. This ossification is most frequently met with in old persons, and especially those who have been addicted to a too generous mode of living. The morbid sounds produced by these obstructions at the various orifices will resemble those of the bellows, file, or saw, according to the degree of the obstruction; and sometimes a triple or even a quadruple sound will be perceived instead of the two normal sounds. The effects of these obstructions will be sanguineous and serous congestions, oppressions of the breath, apoplectic seizures, and other symptoms of embarrassed circulation.

10. *Ruptures of the Heart.*—Ruptures are sometimes found to occur, not only in the valves and columns of muscular fibres within the heart, but also in its parietes. The effect of such injuries will depend upon their extent and situation. A valve, or one of the bundles of muscular fibre, cannot be broken through without causing much inconvenience to the free circulation of the blood; but it seldom happens that the parietes of either cavity of the heart are sufficiently injured to allow the free passage of blood into the pericardium without instant death being the consequence.

11. *Persistence of the Foramen Ovale.*—It is by no means very uncommon to meet with cases in which the opening leading from the right to the left auricle of the heart has not been properly closed up at the time of birth. According to the extent of the communication thus remaining, a greater or less proportion of venous blood will pass into the left side of the heart, and, being there mixed with red blood, circulate through the arterial system.

The symptoms of this disease are blueness of the skin, lips, and nails; a temperature of the body below that which is natural and healthy; shortness of breath, palpitations, faintings, a sense of suffocation induced by slight exertion, and sometimes a great disposition to hæmorrhage and depression from small losses of blood. This disease has, from the colour of the skin, been named 'blue disease,' 'morbus cæruleus,' or 'cyanosis.'

12. *Nervous Diseases of the Heart.*—These are met with chiefly in women suffering from anæmia, chlorosis, hysteria, and other nervous symptoms; and in men in whom a naturally nervous temperament has been rendered more irritable by the too free use of stimuli or by depressing passions. In all these cases great attention should be paid to the general health. In the cases of anæmia and hysteria, iron medicines and the shower-bath will be of the greatest service; and, as far as possible, sources of anxiety should be removed.

HEART'S-EASE, or PANSY, is the cultivated state of the plant called *Viola tricolor* by botanists, improved by crosses with *Viola altaica*, and other allied species.

Several hundreds of beautiful varieties are now common in gardens. Although they will all grow in almost any kind of soil, yet, in order to bring the finer sorts to any degree of perfection, a loam, mixed with sand, and highly manured, is absolutely neces-

sary. By proper treatment they may be had in full flower at two different seasons—from April to June, and from September until the frost destroys them.

The original species from which all these varieties sprang are easily preserved; but this is not the case with many of the finer sorts, which, as in animals and in other plants, the higher they are bred, and the finer the kinds, are in proportion difficult to keep in health. The principal causes which affect them are excessive heat in summer, and wet and cold in winter. They are, however, easily propagated, and only require to be looked over frequently, when, if any of them are found damping or decaying at the bottom of the stem, the top must be taken off, and struck. When there is danger of losing any of the sorts during winter, the best way is to strike a quantity in autumn, and to place hand-glasses over them until spring; at that time those which are alive may be soon multiplied in abundance.

Where fine large flowers are wanted, the plants should always be struck from cuttings the same season, and grown rapidly. In striking them artificial heat is altogether unnecessary, unless when the operation is performed early. All that is required for the purpose is a small hand-glass to place over the cuttings, and a mat to shade them during bright sunshine. After they are well rooted, they must be taken carefully up, and planted in a bed previously prepared for them. They will then flower in great profusion from April to June.

Varieties are obtained from seed. In order to have them fine, considerable care is requisite in selecting the seed. It must always be gathered at those seasons when the plants flower in the greatest perfection, and from the best formed and largest blossoms. They will generally be found in this state in the early part of the season, from April to June, or in autumn, after the greatest heat of summer is past; at other seasons the flowers are smaller, and it is found that this affects the seed. The seed should be sown in spring, in light soil, with the protection of a cold frame. When the plants are very young, they must be removed from the frame and planted thinly under hand-glasses, where they will remain until they are sufficiently strong to be planted out in the flower-garden. At every shifting they must have plenty of water, and be carefully shaded during bright sunshine.

HEAT. This great natural agent becomes sensible to us in the first instance by our bodily sensations, but we find afterwards its effects in the various changes which it is capable of producing on all substances. Expansion, fusion, evaporation, thermoelectric currents, and various physiological phenomena, are effects of heat, or at least accompany its absorption.

Every existing substance may be regarded as a source of heat. In this respect the sun is the most important natural source which our system possesses, its heat when condensed in the focus of a lens being exceedingly intense. When concentrated by a number of powerful lenses on one scale of a balance of extreme sensibility, no derangement of equilibrium ensues; as far, therefore, as experiment can inform us it is imponderable, and the increase or diminution of heat in any body is therefore unaccompanied by any alteration of weight.

Heat may be produced artificially by any means which propagate agitations internally in bodies: hence friction, hammering, percussion, sudden condensation, chemical combination, and electrical discharges are all proper to produce or rather to develop heat.

Heat radiates from all bodies in straight lines and in all directions, and in the law of its emanation it resembles light, its intensity diminishing in the same proportion as the sine of the angle of emanation. If we conceive two balls which are heated unequally to be inclosed by a concave surface which by any means is preserved at a uniform temperature, the radiation of heat from the warmer ball, directed on the colder, being more copious than the radiation from the latter on the former, the temperature of the hotter will sink, and of the cooler rise, in proportion to the difference of radiations; and this will continue until the temperatures become permanent, in which case the radiations are necessarily equal.

One consequence of the free radiation of heat in open space is, that its intensity must vary inversely as the square of the distance from the origin. Hence every portion of space has a determinate temperature due to the amount of radiation, not only from the sun and fixed stars, but also of the non-luminous bodies of each system.

But though the laws of the free emanation of heat and light are similar, those of their transmission through substances are very different. When a metallic body is but a little heated in a fire, we have heat unaccompanied by sensible light; and in the lunar rays the light, though originally transmitted from the sun, arrives at our planet without any sensible heat, even when collected in the focus of a burning-glass. Again, a plate of glass placed before a common fire will intercept the heat until it becomes itself sufficiently heated to radiate. When, however, the source of heat is more intense, a small portion will be directly transmitted; while for the solar rays we find the heat is transmitted as well as the light. It is still more remarkable that, when the solar rays are decomposed by transmission through a glass prism, the differently coloured rays of the spectrum have each a different intensity of heat, the least refrangible possessing the greatest portion; the greatest heat is found at the place occupied by the extreme red rays, or even a little beyond them.

Not only may radiant heat be collected in a focus by refraction through a lens, but also by reflexion from a polished concave mirror.

The power of radiating heat is certainly the most universal mode of its propagation between different particles of matter, as well as through considerable spaces. However, it is usual, for greater simplicity, to designate this propagation through solid bodies as *propagation of heat by contact*. Whichever of these two views may be adopted, we are led to important physical distinctions between different homogeneous substances, viz., their conducting powers internally and externally. Newton's formula to represent the heat communicated from one body to another of the same physical nature, when in contact, is $h(t-t')$; in which t and t' are the temperatures of the two bodies, and h is a constant, proportional to the interior conductivity of the particular substance.

A formula for the heat lost by a body of uniform temperature when subject to a current of air is $H(t-T)$, T being the temperature of the air in contact, and H a constant, depending on the exterior conductivity.

The exterior conductivity may be very different in the same body by slight alterations in the smoothness or even colour of the surface. It is by this antagonist principle that heat acquires a permanent state, corresponding to the different positions of the parts of bodies relative to the sources of heat and the dispersing surfaces.

The mathematical theory of the distribution of heat is founded on the principle that, when a body has arrived at a permanent state of temperature, the quantity of heat given out by any particle to the adjacent colder region must be equal to that received from the warmer particles near it, and conversely. For example, suppose a solid body to be contained by two parallel planes of indefinite extent, and of uniform but different temperatures. In this case, the exterior conductivity through the sides being prevented, the temperature will be uniform in any section of the body parallel to its bases, but will increase from the lower plane in an arithmetical progression to the upper. Now, suppose a thin cylindrical rod to be placed in a medium of which the temperature is constantly zero, while its extremities are maintained at constant but different temperatures; in this case, on account of the exterior conductivity, the distribution of heat will follow, at equal distances along the rod, a geometrical progression increasing from the colder extremity to the hotter.

The propagation of heat in liquids depends very little on any communication by contact. If we place a heated plate on the surface of water in a vessel, but so as not to touch the edges, a thermometer placed in the water will indicate little or no alteration of temperature; and if the bottom of a vessel of water be heated, the heat will be distributed through the liquid only by currents of particles ascending from the heated part. Little as is the conducting power of liquids, that of gases is probably much less, if any; but there would be great difficulty in establishing this experimentally. The effect of heat on gases is to increase proportionally their elasticity, and this disturbing force produces violent motions in their parts, so that the whole shortly acquires a uniform temperature, when other forces, such as gravity, are not taken into consideration.

These three modes of the propagation of heat exist in our globe, and are the cause of important phenomena in the distribution of climate.

First, the great mass of earth, considered in reference to its solid parts, has an external source of heat in radiation, principally from the sun, which compensates the radiation from the interior of the earth. If we suppose the mass of the earth to have been at any remote period at a very high temperature, the effect of the radiation of its heat through the colder surrounding space would be to cool first the superficial strata, and successively, though in a less degree, the internal strata, until a permanent state was reached, when the diminished radiation would be exactly compensated from external sources. Hence, on descending below that comparatively shallow envelope affected with diurnal or annual variations of

temperature, we ought to find a continually increasing temperature towards the centre, a result which has been verified in the mines in several countries in Europe.

The propagation of heat by motion in fluids has an immense tendency to equalize the temperatures of different latitudes; and the unequal depths of different places in the bed of the sea would, from the same cause, produce currents warmer than the adjacent water. The elasticity acquired by portions of the air in contact with the warmer regions of the globe destroys the equilibrium of that fluid, and generates winds of which the heat is communicated to the districts traversed, while the counter-currents, or cold winds, rush forward to occupy the abandoned spaces. [TRADE WINDS.]

Chemical Agency of Heat.—The agency of heat in promoting chemical action is important and extensive; in some cases no combination can take place without it, and in others it greatly facilitates chemical combination, while in some instances it decomposes compound bodies, and resolves them either into simpler or elementary forms of matter. In the solution of salt in water, an increase of heat, by increasing the affinity between the solid and the liquid, increases the solvent power. Many gases, on the contrary, are more soluble in cold than in hot water. In the case of oxygen and hydrogen, and in many similar cases, heat has no effect on the mixture until it actually produces combination, with change of state. The action of oxygen upon metals very greatly depends upon the degree of heat.

Lavoisier invented an instrument called the calorimeter for estimating the amount of heat evolved during chemical combinations. It is figured on the Plate, fig. 15. It consists of two metallic vessels, A B C D, A' B' C' D', one contained within the other, and kept separate by small pieces of wood or glass. The space between is filled with broken ice. This, melting and constantly renewed, keeps the interior vessel at zero. Within this is another vessel, A'' B'' C'' D'', separated from the middle one by ice. Any body of higher temperature introduced into the innermost vessel will be cooled and will communicate its heat to the water, which will show the amount evolved.

Count Rumford's calorimeter (fig. 16) consists of a vessel of sheet copper, with a worm tube in the interior, making three revolutions. This tube introduces the heating gas. Bodies burned at the mouth below, send up their gases through the tube, and the heat communicated to the water will raise its temperature. Fig. 17 is a small pump used with this, when ether or alcohol is to be burned. The liquid is introduced at A and burned at B.

There are some gaseous compounds which can scarcely be produced by the direct action of heat on their elements: thus oxygen and nitrogen do not unite, even when strongly heated, so as to form nitrous acid or any other compound; but the heat which accompanies the electrical spark seems capable of producing this effect. There are a few cases in which heat by direct action, and without the aid of any intervening affinity, is capable of decomposing compounds.

Heat has also great power in modifying as well as in causing chemical action, and different degrees of it produce very opposite effects in some cases. If

we heat mercury to about its boiling point, exposed to the air, it becomes peroxide; but if we expose this product to a higher temperature than was required for its formation, it is then again resolved into metallic mercury and oxygen gas.

The dilatation of substances by heat is nearly proportional to the increase of temperature, except when they are about to change their physical or chemical states; thus water near the freezing point expands when the temperature is diminished, which is probably owing to the different arrangement assumed by its constituent particles preparatory to crystallization. In gases the law is very simple; their expansion (even when containing vapour) is 0.375 of their volume at the freezing point, when their temperature is raised to the boiling point; and is equable during the interval.

Elastic vapours mixed with air add to its elastic force. Let fig. 13 represent a common condenser gauge formed of a bent tube, open at one end and closed at the other, containing some mercury. Moisten the interior of the tube with water and observe the tension, then place the instrument in warm water and again observe the tension; it will be seen that the increase is greater than it would be with dry air or gas only. An instrument called cryophorus, invented by Dr. Wollaston, is represented at fig. 14. Two glass balls communicating by a tube inclose a small quantity of water. This is made to boil, and the open end is hermetically sealed. When one of the balls is placed in a freezing mixture, and the water is brought into the other, the vapour is condensed, and thus the vacuum draws the evaporation so rapidly from the water as to produce freezing of it in the ball.

The following table gives the dilatation of a unit length of different solids from the freezing to the boiling point, and is a mean taken from several observers:—

Glass tube, . . .	00083	Copper, . . .	0017
Crown glass, . . .	00089	Brass, . . .	0018
Platinum, . . .	00093	Silver, . . .	0020
Palladium, . . .	001	Tin, . . .	0022
Cast Iron, . . .	0011	Pewter, . . .	0023
Steel, . . .	0012	Grain Tin, . . .	0025
Do. tempered, . . .	0013	Lead, . . .	0028
Gold, . . .	0015	Zinc, . . .	0030

A simple means of observing the expansion of a liquid by heat is seen at fig. 1. A flask is filled with a liquid and held over a lamp. So soon as the temperature begins to increase, the liquid will rise above the point A. The dilatation of gases or air is seen in fig. 2. A common phial, with a glass tube passing through the cork, has a small quantity of coloured fluid at the bottom, into which the end of the tube reaches. When heated over a lamp, the air expands and forces the fluid up the tube. This and fig. 3 are different forms of the air thermometer. Fig. 4 is the tube and bulb of the common thermometer. The freezing point is determined by immersing the thermometer in the water of melting ice, and the boiling point by immersing it in boiling water where the steam is excluded from the glass, as in the instrument shown in fig. 5, 00 being an aperture for the escape of the steam. Plates of different metals of unequal expansibility are some-

times used together as compensation balances for chronometers (fig. 6) and as thermometers (fig. 7). For meteorological purposes, in which it is desirable to have the changes of temperature registered, an instrument such as that represented in fig. 8 is used, or such as those shown in figs. 9, 10, and 11. The two last represent an instrument constructed by Gay-Lussac. Within a large tube, C D, is a small one, B H, the former being filled with mercury from F to E. Suppose the bulb, A, and the tube, C D, filled with salt-water at 20°. Should the temperature now be lessened the mercury would enter at B and fall to A, and the remainder poured into the graduated tube, G, would indicate the depression of temperature. Fig. 12 represents another instrument called the differential thermometer, used for the same purpose.

Instruments have been invented for observing the amount of heat bodies give out in cooling. One of these is represented in fig. 18; M M' M'' M''', is a large thin copper balloon immersed in a trough of water, and kept there by the cross beams, R R', R R'. A thermometer inclosed in a hollow tube, S T, is passed by means of a long neck through a cork in the opening of the balloon. Fig. 19 shows the bulb of the instrument when being heated, the plates A A' screening the plate A B from the heat. A tube, D E F, passes from the top of S T, where there is a stopcock, to the plate of an air-pump, H K. From r' to m is a tube containing muriate of lime, over which the gas passes by way of the bent tube, m n p r s, into the glass air-holder, v, where the observations are made. Cooling takes place generally by radiation. Experiments on the radiation of heat are made by the apparatus represented in fig. 20, which consists of two concave mirrors of polished tin twelve feet apart. In the focus of one is the bulb of a thermometer, and in the focus of the other a ball of hot iron. The thermometer in the focus may be compared with another at the same distance from the hot ball without the focus, and it will be found to stand much higher. Fig. 21 is another instrument used for the same purpose. It is a square tin canister filled with hot water, having its four sides coated with different substances with their respectively different powers of radiation.

HEAT, ANIMAL. The conversion of the food of man and the higher animals into nutriment for the body is attended with changes which produce an evolution of heat which constantly maintains the temperature of an animal at a point above or below, according to circumstances, the temperature of the medium in which it exists. The degree of heat possessed by animals not gifted with the power of locomotion is very small above that of surrounding media, and in this respect resembles the heat given off by plants. [HEAT OF VEGETABLES.] In proportion as animals possess the power of locomotion, they evolve heat from their bodies. This arises from the fact, that where the muscular system is most exercised there is greatest demand made upon the nutritive processes going on in the system. We should therefore expect to find that the quantity of heat developed in the invertebrate animals was less than that in the vertebrate class. This fact has been recorded by many observers, as, for instance, by John Hunter, in the Annelida, and by Newport, in the Insecta.

Amongst the vertebrate animals, fishes and rep-

tiles have the lowest temperature. Dr. Davy, John Hunter, and others, have found that fishes have a temperature of from 0.7° to 2.7° above the surrounding medium.

In man the temperature of the accessible parts of the body, as the mouth, axilla, &c., is usually between 97.7° and 98.6°. The human blood is found to have a temperature in health varying from 100.6° to 101.75°; in disease it rises to 106° or 109°. In healthy persons the temperature is said to attain its maximum during the day, and to fall from 1.8° to 2.7° during sleep. Dr. Davy has also found that the temperature of the interior of the body is 2.7° to 3.6° higher in tropical than in temperate climates. Most of the mammalia have a higher temperature than man, and birds develop a greater quantity of heat than any other class of animals. This arises from the nutritive changes going on in the bird in order to support the enormous muscular power which it is compelled to exert during flight.

There is now no question that the cause of animal heat is the chemical changes which are going on in the nutrient fluid of the body. During the act of respiration a large quantity of oxygen gas is taken into the lungs, which is absorbed by the blood. In this fluid it meets the various compounds of carbon which have been taken in with the food; and the consequence is a union of the oxygen with the carbon, and the formation of carbonic acid gas, which gas is given out when the blood again reaches the lungs during expiration. When carbon and oxygen unite out of the body, heat is the result, and the same thing occurs when they unite in the body; and it is through the medium of this change that the bodies of animals are raised to a given temperature by the circulation of the blood through the system. It has been calculated that there is more oxygen absorbed than is given out of the system in the form of carbonic acid gas; it is probable that this enters into combination with hydrogen and compounds of hydrogen, nitrogen, and carbon, and thus contributes to the raising of the animal heat.

This theory of animal heat explains many well-known phenomena; as, for instance, the slight independent warmth of the fœtus, and of those young animals which are born in an imperfectly developed condition. The low temperature of persons with *morbus ceruleus* [HEART, DISEASES OF], where the blood is only imperfectly oxygenated, and the cold experienced by aged and debilitated persons in whom a small quantity of blood circulates slowly; as also the increased temperature observed in persons labouring under attacks of inflammatory disease, where the blood circulates rapidly—are confirmatory facts. The phenomena exhibited by the *hibernation* of animals are explained by this theory.

HEAT OF VEGETABLES. Whenever oxygen combines with carbon to form carbonic acid, an extrication of heat takes place, however minute the amount. Such a combination occurs much more extensively during the germination of seeds and the impregnation of flowers than at any other time. At the first of these periods extrication of heat takes place to a considerable amount, as is remarked in the germination of barley heaped in rooms, previously to being manufactured into malt; in the latter it also occurs, but in consequence of flowers not being con-

fined in close cases, the heat is lost as soon as it is disengaged, and never accumulates, except in a few special instances. It is, however, only when large quantities of flowers expand within close cases that this phenomenon is particularly remarkable. Accordingly, in the spathe of araceous plants it has been remarked at its greatest intensity. Lamarck, Senebier, and De Candolle found the flowers of *Arum maculatum*, between three and seven o'clock in the afternoon, as much as 7° Réaumur warmer than the external air. Schultz found a difference of 4° to 5° between the heat of the spathe of *Canadium pinnatifidum* and the surrounding air at six to seven o'clock P.M. Hubert and Bory de St. Vincent assert that at sunrise the spathe of *Arum cordifolium* acquires in the Isle of France an elevation of 30° Réaumur above the atmosphere. Finally, Messrs. Vrolik and Vriese at Amsterdam, and Adolphe Brongniart at Paris, have confirmed the fact by new observations in the hothouses of those cities. It has also been found that in winter plants have a higher temperature than the surrounding atmosphere, and in summer a lower one.

Hence it appears that plants not only have, under all circumstances, a temperature different from that of the external air, being warmer in winter and cooler in summer, but that under particular circumstances the heat of certain parts is elevated in a very remarkable degree. We know that heat is necessary for germination and for vegetable impregnation. May we not therefore conclude that nature has given to plants the power of extricating for themselves an additional supply of caloric at these important periods?

HEATH. [CALLUNA; ERICA.]

HEATH-COCK. [BLACK-COCK.]

HEATHCOAT, JOHN, was born in 1784 at Long Whatton in Leicestershire. His father, a small farmer, apprenticed him at an early age to a framesmith, with whom he acquired a practical knowledge of the mechanism of the stocking frame and warp machines. By the application of a clever apparatus to one of these machines, mits of a lace-like appearance were produced, which first suggested to the ingenious inventor the idea of making lace by machinery. Having completed the term of his apprenticeship, he commenced business on his own account as a "setter up" of hosiery and warp frames in Nottingham, where in his leisure hours he pursued with untiring energy the design of constructing a machine that should simultaneously do the work of the pillow, of the multitudinous pins, threads, &c. This great conception, after wondrous efforts, was at length successfully perfected. Reward followed quickly on success: the first square yard of plain net was sold at 5*l*. For the last twenty-five years the average price has been 5*d*. per yard. In 1816 the factory in which Mr. Heathcoat's business was carried on at Loughborough was attacked by the Luddites and the lace frames destroyed. This disaster led to the removal of the manufacture to Tiverton. On the passing of the reform bill Mr. Heathcoat was returned as member for that borough, and continued until within two years of his death in the regular discharge of his parliamentary duties. At the age of seventy-seven, January 18, 1861, after repeated attacks of paralysis, he died at his seat, Bolham House, Tiverton.

HEATING APPARATUS. [VENTILATION.]

HEAVEN. This word was used of old, and is still used in popular physical science, to signify the firmament or vault of heaven. The Bible speaks (Gen. vii. 11) of the 'windows of heaven.' In theology, however, it refers to the scene or place or condition of eternal life; to that portion of infinite space where the Deity is supposed specially to dwell, and which he has from the beginning of time pre-ordained for the inheritance of the good after death.

All religions teach the eternal and imperishable nature of the human spirit, and the continued existence of souls after death, and even the heathen, when weeping over the corpse of one he loves, does not fail to lift his tearful eyes to the home beyond the grave. Of course, among the different nations the most contradictory ideas prevail; some believe that in the next world the soul will live in a state of sensual bliss, in the midst of lovely groves and gardens, where are spread richly-decked boards, at which they may feast whenever they please. Others believe that the soul sleeps in the grave until the great day of judgment, when the dead shall arise and receive their reward. Others, again, think that the spirits of the departed roam about in some paradise, where their greatest happiness consists in recounting the deeds performed by them in their former existence; while others hold that before the soul is admitted into heaven it must undergo a period of probation, during which it will be cleansed from all earthly wishes, cares, and impurities, in order that it may ultimately enjoy unmixed and eternal bliss. The Elysian Fields of the Greeks and Romans, and the Elysium of classical mythology, is, in all essential respects, the natural equivalent of the heaven of the just. The Mohammedans hold the notion of seven heavens, rising one above the other according to degrees of dignity and glory. Each race and nation forms to itself its own ideal of enjoyment, and calls it heaven. Speculations on the subject are, however, vain and profane; human language has no words to express the eternal life, and the things of earth offer no analogy to it. Even biblical revelation is almost silent on this subject, and St. Paul deprecates the vain endeavours of inquisitive minds to pry into it.

Christians generally believe the word to signify the abode of the Most High, and the special seat of his glory, in which the angels minister to him, and the saints live in everlasting bliss and perfect happiness. Many controversies have arisen as to the precise time of the spirits entering paradise—whether immediately after death or only after the general resurrection.

HEBE, in Greek literature, the Goddess of Youth and the cupbearer of Olympus, a daughter of Jupiter and Juno, who gave her as a wife to Hercules in reward for his achievements.

HEBER, REGINALD, second bishop of Calcutta, was born April 21, 1783, at Malpas in Cheshire, of which place his father was for many years co-rector. He gave early indications of his poetical talents, and at seven years old he had translated Phædrus into English verse. At eight he was sent to the grammar-school of Hawkhurst under Dr. Kent, and in his thirteenth year he was placed in the school of a clergyman, near London. He remained here about

three years, and in November, 1800, was entered at Brasenose College, Oxford. In his first year at the university he gained the prize for Latin verse. In the spring of 1803 he wrote his prize poem, 'Palestine,' which has obtained a permanent place in English literature. In 1804 he became a fellow of All Souls. The year after he had taken his degree he gained the Bachelors' prize for an English prose essay on the 'Sense of Honour.' About the middle of 1805, in company with his friend Mr. John Thornton, he set out on a continental tour, and returned to England in October, 1806. In 1807, before he had obtained his degree of M.A., he took orders, and was instituted by his brother Richard to the family living of Hodnet. In April, 1809, he married Amelia, youngest daughter of Dr. Shipley, dean of St. Asaph. While discharging the duties of his parish with much earnestness, he was ardently attached to the pursuits of literature. He was a frequent contributor to the *Quarterly Review* from its commencement. In 1812 he commenced the preparation of a 'Dictionary of the Bible,' but other duties compelled him to suspend this work, and no part of it was ever published. In the same year he published a small volume of 'Poems and Translations for Weekly Church Service.' The composition of his 'Hymns,' with a view of improving the psalmody and devotional poetry used in churches, was also a favourite recreation. His political views were those of the High Church and Tory party, but devoid of all bitterness. In 1815 he was appointed Bampton lecturer, and the subject he selected was 'The Personality and Office of the Christian Comforter.' In 1817 Dr. Luxmore, the bishop of St. Asaph, appointed Heber to a stall in that cathedral. In 1819 he edited the works of Bishop Jeremy Taylor. His other works consist of 'Parish Sermons,' preached at Hodnet, and Sermons preached in India. In April, 1822, he was elected preacher of Lincoln's Inn. At the end of that year his friend and connection, the Right Hon. Charles W. Williams Wynn, who was at the time president of the Board of Control, offered him the vacant see of Calcutta, which he accepted after two refusals. He embarked for his diocese, June 16, 1823, and on the 15th of June, 1824, began his visitation. The Journal which he kept during his visitation, and which has been published in three octavo volumes, shows the extent of his observations. On the 3rd of April, 1826, after investigating the state of the mission at Trichinopoly, he retired to use a cold bath, in which he was found dead about half an hour afterwards. Within less than three weeks he would have completed his forty-third year.

HEBERDEN, WILLIAM, M.D., was born in London in 1710. In 1724 he was sent to St. John's College, Cambridge, of which, six years afterwards, he was elected a fellow. He studied medicine in Cambridge and London, and after taking his degree practised as a physician, and delivered an annual course of lectures on materia medica in the University of Cambridge. In 1746 he was elected a fellow of the Royal College of Physicians, and soon after left Cambridge, and commenced practising in London, where he at once met with the greatest success, and obtained the highest reputation. In 1750 he was elected a fellow of the Royal Society, and in 1778 an associate of the Royal Society of Medicine in Paris.

After thirty years' extensive practice, finding his health declining, he gradually withdrew himself from his profession to retirement at Windsor, where he died in 1801.

HEBRADENDRON, a genus of the natural family of *Guttifera*, established for the Gamboge Tree of Ceylon.

The gamboge of Siam is in cylinders, either solid or hollow, usually called *pipes*: it is supposed to have this form from being so rolled, or from being poured into the hollow of bamboos.

The Ceylon gamboge is usually considered inferior to that sent from Siam. No doubt, however, some of very excellent quality is produced in Ceylon by the tree which has been called *Hebradendron cambogioides*. Dr. Graham ascribes its inferiority to want of care in preparing the article for market.

The *H. cambogioides* forms a moderate-sized tree. The gamboge oozes out in a semi-liquid state, but hardens on exposure to the air, and is scraped off by the collectors next morning. This tree is found in various parts of Ceylon. Its favourite abode seems to be low sandy ground, but it is also found 100 miles inland, at so high an elevation as 2000 feet above the sea.

HEBREW LANGUAGE forms a branch of that extensive family of languages which are known by the name of Semitic; a name which is derived from the real or supposed descent of the people who speak those languages from Shem, the son of Noah. The Semitic languages may be divided into three branches: the Arabic, to which the Ethiopic is closely allied; the Aramæan, consisting of two dialects—the Babylonian or East Aramæan (sometimes but erroneously called Chaldee), and the Syriac or West Aramæan; and the Hebrew, to which the Phœnician and Punic are closely related. Of these languages the Arabic is the most copious, and the Aramæan the poorest and least developed; the Hebrew holds an intermediate rank between these, being more perfect than the Aramæan, and inferior to the Arabic.

The Hebrew language derived its name from the Hebrews, who date their origin from Abraham, who is called 'the Hebrew' in Gen. xiv. 13. The etymology of this word is doubtful.

The Hebrew language appears to have been formed in Palestine by a union of the ancient Aramæan, which was brought by the Abrahmites from Mesopotamia, with the Phœnician or Canaanitish, the language of the original inhabitants of the country. That the Phœnician and Hebrew languages were very closely allied is evident from the Phœnician names of persons and places, and from the specimens of the Phœnician language which we possess in coins and inscriptions. The long settlement of the Hebrews in Egypt, and their forty years' wandering in the wilderness, must have had an important influence upon their language; but the number of Egyptian words received into it appears to have been small.

Many critics have divided the history of the language into four periods:—I. From Abraham to Moses. II. From Moses to Solomon. III. From Solomon to the Babylonish captivity. IV. From the Babylonish captivity to its final extinction as a spoken language. But there are in reality only two periods in which any difference can be traced in the language; the first extending from the time of Moses

to the reign of Hezekiah, and the second from the reign of Hezekiah to its final extinction as a spoken language. The language in which the Pentateuch is written differs so little from that of David, Solomon, and Isaiah, who lived many centuries after the time of Moses, that many critics, supposing it impossible that a language should have remained stationary for so many centuries, have maintained that none of the books of the Old Testament were written previous to the time of David and Solomon. It is not very easy to disprove this opinion; but the remarks of Ewald on this subject appear worthy of attention. He observes in his 'Hebrew Grammar' § 7 (Eng. trans.), that 'the Hebrew language in the first four books of the Pentateuch, which contain records of unquestionable antiquity, partly by Moses or from his time, appears already, a few minutæ excepted, fully developed.'

The conquests of the Assyrians and Chaldeans from about B.C. 720 tended to introduce the Aramæan language into Palestine. The Aramæan colonies (2 Kings xvii. 24), which were planted in the kingdom of Israel to supply the place of the Israelites who had been carried into Assyria by Salmanser, must have caused the spread of the Aramæan language in the northern parts of Palestine even before the destruction of the kingdom of Judah. The long residence of the Jews in Babylon after the destruction of Jerusalem by Nebuchadnezzar caused the extinction of the Hebrew as a spoken language, at least among the common people. After their return to Judea, according to the edict of Cyrus, it appears, from a passage in Nehemiah (viii. 8), that the common people did not understand the Scriptures when read to them in the Hebrew language. But Hebrew continued to be spoken by the upper classes for a considerable time after the Babylonish captivity. The prophecies of Haggai, Zechariah, and Malachi, who lived in the latter part of the sixth century B.C., are written in tolerably pure Hebrew. The inscriptions of the coins of the Maccabees are in Hebrew; and the Hebrew language does not appear to have been discontinued in writing and conversation among the upper classes till the century preceding the birth of Christ.

But the Hebrew, from the period of its extinction as a spoken language, has been always more or less cultivated by the Jews. After the destruction of Jerusalem by the Romans, numerous schools were established by the Jews, in which their language and literature were taught. Of these schools the most celebrated were those of Tiberias and Babylon. The Mishna, which contains the traditions of the Jews and interpretations of the Scriptures, is supposed to have been compiled in the latter part of the second or the beginning of the third century, by Rabbi Jehuda. The Mishna was considered from this period one of the principal works of Hebrew literature, and the Rabbis of Tiberias and Babylon wrote numerous commentaries upon it. These commentaries were at length collected into two separate works, which were entitled the Jerusalem and Babylonian Talmuds.

The Christians gave very little attention to the Hebrew language before the Reformation. The publications of the Buxtorfs in the seventeenth century tended to diffuse the language among Christians.

The Grammar of Schultens, which appeared in 1731, and which may still be consulted with great advantage by Hebrew scholars, contained a much clearer development of the principles of the language than the Buxtorfs had given. His knowledge of Arabic enabled him to compare the forms of that language with the Hebrew, and thus to draw the attention of scholars to the important fact that the study of the cognate languages is necessary to obtain an accurate knowledge of Hebrew. But the publications of Gesenius and Ewald in the present century, have done more to facilitate the acquisition of the language than the works of all preceding writers.

Few literary subjects have occasioned greater discussion than the letters, vowels, points, and accents of the Hebrew language. But with regard to the letters, it appears probable that the present square characters in which Hebrew is written were not employed previous to the Babylonish captivity, but that the Phœnician letters were used, which are still preserved with a slight alteration in the Samaritan alphabet. According to the Jewish tradition, the present square characters, which belong to the East Aramæan language, were first introduced by Ezra when he revised the canon of Scripture; but they could not have been universally adopted till a later period, since the Samaritan Pentateuch, which was not introduced into Samaria till after the Babylonish captivity, was written in the ancient character, and the Asmonæans, in the second century before Christ, have also used the same character on their coins.

It is a characteristic of the Hebrew language, according to the system of most modern Hebrew grammars, that the alphabet consists only of consonants, and that the vowels are expressed by means of small points placed above and below the letters. The antiquity of these points has occasioned great controversy among the learned. It appears certain, from many circumstances, that the Hebrew letters were originally written without points. The best arguments on both sides of the question are given in Buxtorf's 'Tiberias, sive Commentarius Masorethicus,' 4to., 1620, in which the antiquity of the points is maintained, and in Capellus' 'Arcanum Punctuationis revelatum,' 4to., 1624, in which their antiquity is denied.

HEBREWS. [Jews.]

HEBREWS, EPISTLE TO THE, a book of the New Testament. There has been much controversy as to whether this book is an epistle or a dissertation; as to the persons to whom it was addressed; and by whom and in what language it was written. It is not necessary to enter into the details of these controversies, and we shall only state the prevailing opinions. The allusions to particular circumstances (v. 11; vi. 9, 10; x. 32, 34; xiii. 19, 22, 23) tend to prove it to be an epistle. The general opinion respecting the persons to whom this epistle was addressed, is that they were the Jewish converts in Jerusalem or Palestine generally. This opinion, as Michaelis has shown, is supported by the contents of the book itself. Concerning the language in which it was written critics have been much divided, some supposing that it was written in Greek, and others that it was written in Hebrew and translated into Greek.

The author of this epistle is equally uncertain. The general voice of tradition assigns it to the Apostle

Paul, but it has also been ascribed to Barnabas, to Luke, to Silas, and to Apollos. In the first ages of the church it appears to have been generally considered as a production of the Apostle Paul. The chief objections against the Pauline origin of the epistle are drawn from the absence of the usual address at the beginning, the superiority of the style to that of Paul's acknowledged epistles, and the resemblance between its style and that of the Alexandrine school. The points above stated are discussed with great ability and candour by Professor Moses Stuart ('Commentary on the Hebrews') in favour of the Pauline origin of the epistle, and Professor Bleek ('Brief an die Hebräer') on the other side. The opinions which assign the authorship to Barnabas, Apollos, Luke, and Silas rest on very slight grounds.

The date depends partly on the settlement of the former question. If Paul was the author, it was probably written during his first imprisonment at Rome, and immediately before he was released (see xiii. 18, 19, 23). Accordingly, most critics refer it to A.D. 61 or 62. In warmth of feeling, elegance of language, and force of argument, this epistle yields to no book of the New Testament.

HEBRIDES, or *Western Islands*, are scattered in the Atlantic Sea, along the western coast of Scotland, between 55° 35' and 59° N. lat., and 5° and 8° W. long. They amount to nearly 200, of which 70 are permanently inhabited. They are usually divided into the Inner Hebrides and Outer Hebrides. The Inner Hebrides consist of the islands nearest the mainland, including, besides those in the Frith of Clyde, Skye, Mull, Islay, Jura, Coll, Rum, Tiree, &c. The Outer Hebrides, popularly called the Long Island, consist of the range of islands stretching in a continuous E.N.E. and S.S.W. direction from Barra Head to the Butt of Lewis. The principal islands in the range are Barra, North and South Uist, Benbecula, and the districts of Harris and Lewis, which two form together one long island. The surface of these islands varies considerably. Some of the larger islands are mountainous, especially those which approach the mainland, such as Arran, Jura, Mull, and Skye, in which the elevated masses rise to the height of 2000 or 3000 feet and more above the sea. The others are in general only hilly, the most elevated parts not exceeding 1500 feet; and in some are not more than from 300 to 500 feet. The rivers are small but numerous, and abound in salmon, trout, and eels; many contain also several other kinds of fish. Some of the islands abound in lakes. Bute and Islay, and also several districts in the island of Skye, are considered fertile. A comparatively small portion of the surface of the whole is under cultivation. The whole area of the islands comprehends 1,592,000 acres, of which mountains, morasses, lakes, and unproductive soil have been computed to occupy 600,000, pasture 700,000, and arable land only 180,000 acres. There are no natural woods on the islands, but several thousand acres have been planted.

Owing to the Gulf Stream the climate is upon the whole mild. Frost and snow are almost unknown in the smaller isles, and they seldom prevail in the larger to any considerable degree.

The great mass of the population resides within a mile of the sea-shore. From their language and

customs it is evident that they are of the same stock with the inhabitants of Ireland and of the Highlands of Scotland.

The people are generally in the greatest poverty, four-fifths subsisting almost wholly on potatoes and fish. The introduction of steam navigation has contributed very much to the improvement of the Inner Hebrides. The herring fishery, formerly an important resource of the people, has greatly declined, as has also the manufacture of kelp, of which, at the beginning of the present century, nearly 6000 tons were produced, fetching sometimes 20*l.* per ton. Except some productions of cotton stuffs at Rothesay, distilling in Islay, and boat-building at Tobermory and Stornoway, the manufactures are insignificant and wholly domestic. The most profitable branch of industry is the rearing of cattle and sheep: the stock of each is estimated at 120,000. The imports are iron, groceries, salt, oatmeal, and peat-fuel in some of the islands; the principal articles of export being live stock, ponies, kelp, wool, cod, ling, herrings, limestone, and slate.

The greater number of the islands are destitute of surgeons, or even of inns, and there is no printing press or newspaper, though a few years ago six branch banks had been established in the Hebrides, which are divided into twenty-six parishes. Most of the inhabitants are Roman Catholics, especially in the outer Hebrides. These islands were ruled mostly by sovereigns of Norwegian descent from the ninth century to 1264, when they were annexed to the crown of Scotland.

The principal towns are Stornoway, a small port in Lewis, Portree in Skye, Tobermory in Mull, and Rothesay in Bute.

As in the mainland portion of the Highlands, many large estates have passed from the old families into the hands of opulent modern proprietors, by whom extensive improvements have been effected.

The Hebrides belong politically to four Scotch counties. Those of them which lie in the Frith of Clyde, between the peninsula of Cantire and the coast of Ayrshire, constitute a county by themselves. [BUTESHIRE.] All the other southern Hebrides, together with the islands of Muck, Rum, and Canna, which are included in the Northern Hebrides, are annexed to the county of Argyle. [ARGYLESHIRE.] The Long Island, except Lewis, constitutes a part of Inverness-shire. Lewis is a part of Ross-shire; and Skye belongs to Inverness.

HEBRON (literally 'alliance'), the name of a city belonging to the territory anciently assigned to the tribe of Judah. Its original name was *Kiryath-arba*, or the city of Arba the father of Anak (see Gen. xxiii. 2; Josh. xiv. 15). It is one of the most ancient cities of the world. Thus the sacred historian says of the Israelites—'They came to Hebron, where Ahiman, Sheshai, and Talmi, the children of Anak, were. Now Hebron was built seven years before Zoan in Egypt' (Numb. xiii. 22). Zoan, or Tanis, was the ancient capital of Lower Egypt. After the conquest of Palestine, Hebron became one of the cities of refuge (Joshua *passim*). Before the accession of the ten tribes to the rule of David, he occupied Hebron as a royal city. Hebron is situated in a deep, narrow, but very fruitful valley, and is even now a place of importance in Palestine. Its

present inhabitants are described as wild and lawless.

HECATÆUS of Milētus, was one of the earliest Greek prose writers. He was present at the deliberation of the Ionians (B.C. 501), and attempted to dissuade them from revolting against the Persian king. (Herod., v. 36.) He is also mentioned by Herodotus (v. 125) as being alive at the time of the flight of Aristāgoras, B.C. 497.

His works, which consisted of histories, genealogies, and geographical pieces, were held in considerable esteem by the ancients. Herodotus (vi. 137) quotes one of his historical works.

The fragments of the writings of Hecatæus have been published by Creuzer in his 'Historicorum Græcorum Antiquissimorum Fragmenta,' 8vo., Heidelberg, 1806, and by Klausen, 'Hecatæi Milesii Fragmenta,' 8vo., Berlin, 1831.

HECATE, one of the ancient Greek divinities, the daughter of the Titan Perseus and Asteria, according to Hesiod ('Theog.,' 411). Her attributes correspond in most respects with those of Artemis; and it has therefore been conjectured that she may originally have been the same as Artemis.

HECATE'SIA, a festival celebrated by the Greeks, and more especially by the Athenians, in honour of Hecate. The numerous statues erected in honour of this goddess were termed *Hecatææ*.

HECATOMB, a Greek word signifying the sacrifice of a large number of victims, usually one hundred. Strictly speaking, the sacrifice should consist of 100 bulls, but inferior animals were often substituted. In the time of Homer it was usual only to burn the legs, fat, and intestines of the animal, the rest being eaten at the feast which succeeded the hecatomb. Hence in Athens this was the most popular form of sacrifice, as it was supposed not only to please the gods, but it likewise fed both priests and people.

HECLA. [ICELAND.]

HECTARE, the principal land measure of the French, which consists of a square of 100 mètres on every side, equal to 2 acres, 1 rood, 35 square poles, and 11½ square yards, English.

HECTOLITRE, a French measure of capacity for liquids containing 100 litres, equal to a tenth of a cubic mètrè, or twenty-two imperial gallons.

HECTOR, the greatest of the Trojan heroes who figure in our accounts of the Trojan War. He was the son of Priam and Hecuba, and married to Andromache. The poet of the 'Iliad' describes him not only as a bold and gallant warrior, but as a hero ennobled by all the more tender and humane virtues. The most tender passage in the 'Iliad' is that in which Hector (vi. 369, &c.), before going to battle, takes leave of his wife and child. He finally fell by the hand of Achilles, and the body was given up by the conqueror to his father Priam. The remains of Hector were buried at Troy, where funeral sacrifices were offered to him as a hero.

HE'DERA, a genus of araliaceous plants, consisting of nearly fifty species, inhabiting chiefly the warmer parts of the world, is interesting to Europeans as containing, among others, the common ivy, with its numerous varieties. This plant, the *Hedera helix* of botanists, does not exactly represent the habit of the genus, for many of the exotic species,

instead of being creepers, adhering to other plants, or to rocks and walls by their sucker-like roots, are trees of considerable size.

HEDGE, one of the most lasting and effectual of fences. Hedges are made of various kinds of shrubs and trees, trained so as to throw out numerous branches along the stem from the surface of the earth upwards; this is done by judicious pruning when they are young. The head being cut off and the side branches shortened, numerous smaller branches spring out, which are shortened in their turn, and form a very compact mass, consisting of the ends of stumps and branches pointing in every direction. Hedges in Britain are generally formed of hawthorn. [CRATÆGUS.] Other shrubs are cultivated with it in order to fill up the blanks at the lower parts of high hawthorn hedges. Beech is also extensively used. Those shrubs which are of a thorny nature are best adapted for hedges. Holly is on this account much in use for gardens and pleasure grounds. Ornamental hedges are sometimes made of lime, yew, box, thorn, hornbeam, elder, sweetbriar, and privet, but they are of little use as fences.

There is a method of repairing hedges which is called *plashing*. It consists in cutting half through some of the stems near the ground, and then bending the upper parts down in a horizontal or oblique position, keeping them so by means of hooked sticks driven into the bank. Thus a live hedge is made, which fills up the gaps in the same manner as a dead hedge would have done, and the bent stems soon throw out shoots. But this should only be done when the stems are young. [FENCES.]

HEDGE-SPARROW, or HEDGE-CHANTER (*Accentor modularis*), the name of a very common and well known species of bird of the family *Sylviadeæ*, or Warblers. It is a gentle and familiar bird, having, to use the words of Gilbert White, 'a delicate song.' It is one of the earliest of our nesting birds. The eggs, four or five in number, are of a greenish colour. The birds rear two broods in a season. The Alpine accentor (*A. alpinus*) is a native of the south of Europe. It has occasionally been met with in Britain.

HEDGEHOG (*Erinaceus*, Linn.), has the body covered with sharp strong prickles instead of hairs. The skin of the back is furnished with muscles so arranged that the animal, on bending its head and pressing its limbs upon the belly, can close itself up like a purse, and present on every part its spines to the enemy. The tail is very short. All the feet have five toes. In the upper jaw there are six incisors, of which the middle ones are the largest; in the lower, two incisors; on each side three false molars; three molars with bristling points; and a little tuberculous molar. The genus *Erinaceus* may be regarded as typical of the order Insectivora. It is spread over Europe, Asia, and Africa.

Example, the common Hedgehog (*Erinaceus Europæus*), the *Riccio* of the Italians, *Erizo* of the Spanish, *L'Hérisson* of the French, *Igel* of the Germans, *Hedgehog* and *Urchin* of the English, *Echinus terrestris* of Gesner, *Echinus (Erinaceus) terrestris* of Ray, and *Acanthion vulgaris* of Klein. There can be little doubt that it is the *Echinus* (Εχίνος) of Aristotle.

The hedgehog is too well known to need here any

explicit details. It is insectivorous, but also devours slugs, frogs, small snakes, and eggs, being therefore mischievous in game preserves. It is plantigrade; inhabits copses, woods, and thick hedgerows; is nocturnal; and hibernates. The female makes a nest, and produces in summer from two to four young, blind at their birth, with the soft rudiments of the prickles only just apparent. On the continent in many places the flesh of this animal is eaten. The Romans used its prickly skin for hackling hemp.

HEDY'SARUM, a genus of plants belonging to the natural order *Leguminosæ*. The species are herbs or under-shrubs. *H. coronarium*, French honeysuckle, is a native of Spain and Italy. It has deep red or white flowers. In Calabria this plant grows wild in great abundance, and horses and mules are fed with it. It grows well in our gardens, but probably would not make a good field crop. *H. fruticosum* is a native of Siberia in sandy places. It has a pale purple flower, and is a very handsome plant. Horses eat it with avidity, and it may be made useful in fixing sand, in which it grows readily. *H. Mackenzii* is a native of arctic America, about the Saskatchewan. The flowers are large and of a red colour. This was described as a liquorice plant by Sir A. Mackenzie, and named after him. The whole plant has a sweet taste. *H. lineare* is used in Cochinchina as a stomachic, and *H. alpinum* is used in Siberia for the same purpose. The *H. sennoides* of Willdenow, now *Ornocarpum sennoides*, has a root which is used in India as a tonic and stimulant. The *H. alhagi* of Linnæus is the *Alhagi maurorum* of recent writers. It is a spiny shrub, and from its branches exudes a sweet substance like manna. *H. tuberosum* of Roxburgh, *Pueraria tuberosa* of De Candolle, grows in the Circar Mountains, Hindustan.

HEEM, JAN DAVITZE DE, one of the most distinguished of the Dutch fruit and flower painters, was born at Utrecht about 1600, and died at Antwerp in 1674. His son, Kornelis, or Cornelius, was likewise an excellent painter in the same department.

HEEMSKERK, MARTEN, a celebrated Dutch painter, was born at Heemskerk, near Haarlem, in 1498: he was the son of a peasant farmer, Jacob Willemsze Van Veen, but he is known only by the name of his birthplace. Marten was employed by his father in common farm labour, which was particularly distasteful to him. He had given evidence of a talent for the art of design, and he fled to Delft, obtained admission into the house of a painter of the name of Jan Lucas, and he too became a painter. He studied afterwards with Jan Schoorel, at Haarlem, and his earliest works of distinction were painted in the style of that master. He painted for some years at Haarlem with great success. In Rome he distinguished himself as an imitator of Michael Angelo: the jealousy of the Italians, however, forced him to return to his own country. There are scarcely any works by Heemskerk now at Haarlem. He died very rich, and, though twice married, childless, at Haarlem, in 1674. The engravings after his works, by various masters, amount to many hundreds.

HEERE, LUCAS DE, a distinguished painter and poet, was born at Ghent in 1534. His father, Jan de Heere, was a good sculptor, and his mother

excelled in miniature painting. Lucas was placed with Francis Floris, after he had made sufficient progress with his father to benefit by the instruction of Floris. He painted in France; and visited England in the reign of Queen Elizabeth, whom he painted several times.

The principal of Lucas' poetical works was the 'Garden of Poetry'—'Boomgaard der Poësië': he commenced also, in verse, the 'Lives of the Painters,' but this has been lost. He died at Ghent in 1584.

HEEREN, ARNOLD HERMANN LUDWIG, was born at Arbergen, a village near Bremen, on the 25th of October, 1760. His father, who was pastor at Arbergen, gave him his first instruction in religion, Latin, and mathematics. In the autumn of 1779 he went to the University of Göttingen, when he attended Heyne's philological lectures. However, he soon felt that philology, in the narrower sense of the term, was not his vocation, for the things about which he read in the ancients interested him more than the languages themselves. In 1784 Heeren took his degree of doctor in philosophy. In the year following he formed the plan of a new edition of the 'Eclogæ' of Stobæus. He had commenced giving lectures at Göttingen as private teacher, but the opposition between his actual pursuits and what he felt to be his vocation became more and more painfully felt, his spirits began to fail, and his health also began to sink. He resolved to visit Italy, and principally Rome. One of the main objects of this journey was to collate the various MSS. of Stobæus. His stay in many of the principal towns of Germany, France, and Italy, was of great advantage to him. The future historian became acquainted with the world at large; he saw with his own eyes some of the countries to whose history a great part of his future life was to be devoted. On his return to Göttingen in 1787, he was appointed professor extraordinary in the philosophical faculty, and henceforth his life flowed undisturbed by any changes of fortune. Being possessed of wealth, he was enabled to continue his philological and historical studies without anxious cares. In 1796 he married a daughter of Heyne, who remained his devoted and sympathizing companion throughout his life. In 1799 he was appointed ordinary professor of history, as the successor of Gatterer. His reputation as a scholar and historian was already established, for the first two volumes of his Stobæus had appeared in 1792 and 1794 (the third and last was published in 1801). In 1793 and 1796 he had published the first two volumes of his 'Ideen über die Politik, den Verkehr, und den Handel der vornehmsten Völker der alten Welt' (the third and fourth volumes appeared in 1812 and 1815), which is his principal work, and the one on the completion of which he looked as the main object of his life. A fifth edition, in 5 vols., appeared in 1824, &c. In 1799 he published the first edition of his manual of ancient history ('Handbuch der Geschichte der Staaten des Alterthums'). A fifth appeared in 1826. In addition to these works, which followed one another in rapid succession, he had for some years been editing, conjointly with his friend Tychsen, a journal on ancient literature and art (*Bibliothek der alten Literatur und Kunst*), and had written a great variety of essays for other

periodicals, and for the *Transactions of the Royal Society of Göttingen*. His activity was astonishing; and, in addition to all this, he began about the year 1800 to study the history of the middle ages and of modern times, and also lectured upon these subjects. A great work of his, relating to the history of modern times, bears the title of 'Handbuch der Geschichte des Europäischen Staatensystems und seiner Kolonien,' Göttingen, 1809: a fourth edition appeared in 1822. A work on the influence of the Crusades ('*Sur l'Influence des Croisades*,' Paris, 1808) was crowned by the Academy of Inscriptions. A collection of his minor historical works, in 3 vols. ('*Kleine Historische Schriften*'), appeared from 1803 to 1808, and another, embracing all his historical works, in 15 vols., from 1821 to 1826. Most of his works have been translated into English and Dutch. On the death of Eichhorn, in 1827, he undertook the editorship of the *Göttingische Gelehrten Anzeigen*.

In 1827 or 1828 Heeren, in conjunction with Ukert, formed the plan of editing a series of works, containing the histories of the states of Europe. The whole is not yet completed; but among these works there are some of the highest eminence, such as Lappenberg's 'History of England,' and Geijer's 'History of Sweden.' Heeren died at Göttingen on the 6th of March, 1842.

The great merits of Heeren's works, especially of those relating to antiquity, are these: they are usually the result of a diligent study of the ancient writers themselves, and represent the nations in their political and commercial relations in a very lively manner. His works are written in a clear style, and the influence which they have exercised is very considerable.

HEGEL, GEORG WILHELM FRIEDRICH, was born at Stuttgart on the 27th of August, 1770, and was educated at the gymnasium of his native city. At the age of eighteen he proceeded to Tübingen to join the classes of theology and philosophy, where he had for his class-fellow the illustrious Schelling. Dissatisfied with the prevailing system of metaphysics, Hegel sought to supply its deficiencies by the works of Plato, Spinoza, and Kant; and, in the conviction that a truly philosophical comprehension can only be educed by an enlarged and diversified inquiry, he combined with a knowledge of philosophy a profound acquaintance with the natural and political sciences. Upon being admitted to the degree of doctor in philosophy, he accepted an engagement as private tutor, in which capacity he lived for some years, first in Switzerland, and afterwards at Frankfort-on-the-Main, until, on the death of his father in 1800, he was enabled, by the inheritance of a small patrimony, to devote himself without restraint to the study of philosophy. He accordingly proceeded to Jena, where Schelling was teaching his system of *Absolute Identity*, and of which Hegel was at this period one of the warmest partisans. Here he wrote his first philosophical work, entitled 'On the Difference of the Systems of Fichte and Schelling;' which treatise, notwithstanding the sincerity with which Hegel then advocated the views of the latter, contained the germ of that dissent which was afterwards expanded into a peculiar theory. He was also associated with Schelling in conducting the 'Critical Journal of Philosophy;' and among the

most important of the articles contributed by him is that 'On Faith and Science.' In 1806, when Schelling went to Würzburg, Hegel was appointed to supply his place as lecturer; and now for the first time he openly avowed his dissatisfaction with the system of Schelling. The difference between the ideas of the master and disciple was marked still more strongly in the 'Phenomenology of Mind,' which was published at Bamberg, whither Hegel had retired after the battle of Jena. This work contains an account of the several grades of development through which the 'self,' or 'ego,' proceeds; first of all, from consciousness into self-consciousness; next, into reflecting and active reason, from which it becomes philosophical reason, self-cognizant and self-analyzing, until at last, rising to the notion of God, it manifests itself in a religious form.

During his retirement at Bamberg, Hegel conducted the political journal of that town with great ability, and with honesty and candour. In 1808 he was called to preside over the gymnasium of Nürnberg. The benefit of the reforms he effected, both in the discipline and the studies of the school, are still gratefully noticed at the annual commemoration. In 1812 he published his 'Logic,' which was designed, with the 'Phenomenology,' to complete the whole body of science. Hegel employs the term logic in a very extended sense. The general merits of this work were admitted, and acknowledged by the offer of a professorship at Heidelberg. His first course of lectures was attended by a numerous and distinguished class, attracted by the originality of his views, notwithstanding the great obscurity of his style. By the publication of the 'Encyclopædia of Philosophical Sciences,' in 1817, his reputation as a philosopher was established, and Hegel was invited by the Prussian government to fill the chair at Berlin, which had remained vacant since the death of Fichte, in 1814. He successively published the 'Philosophy of Jurisprudence,' two new editions of the 'Encyclopædia;' the first volume of the second edition of his 'Logic;' and several articles in the 'Annals of Scientific Criticism,' which he had established as an organ of his system, and of its application to every branch of art and science. He fell a victim on the 14th November, 1831, to cholera, and was, in compliance with his express desire, buried by the side of Fichte. A life of Hegel has been written by his disciple Rosenkranz, of Königsberg; and a complete collection of his works was published in eighteen volumes at Berlin, 1832-41.

HEGESIAS (*Ἡγεσίας*), a Greek rhetorician and historian, was a native of Magnesia, and lived about the time of the historian Timæus, that is, about B. C. 250. Respecting his life no particulars are known, and his works are lost. He wrote a history of Alexander the Great.

HEGESIAS, the *Cyrenaic Philosopher*, lived somewhat earlier, in the reign of Ptolemæus Philadelphus. His doctrines in the main points agreed with Aristippus, the founder of the Cyrenaic school, who maintained that pleasure was the great object of man's life; but Hegesias and his school denied that kindness, friendship, and benevolence had any independent existence, but that they arise and disappear with our feeling of the want of them. Happiness is a thing impossible to attain, for our

body is subject to many sufferings, and the soul suffers with it. Life and death are equally desirable. Nothing is by nature either agreeable or disagreeable, but becomes so through the circumstances in which a man lives. A wise person therefore looks upon life with indifference, and regards nothing and nobody so much as himself, reducing everything to his own convenience.

HEGIRA, or HEDJRAH, the commencement of the Mohammedan era. It signalizes the flight of Mohammed from Mecca to Medina in the year 622. His life was in danger at the former place, and at the latter he found so much help in waging war with his adversaries that the rise of Mohammedanism was said to date from the time of his leaving Mecca. The Moslem calendar therefore dates from the middle of July, 622, but being a lunar year, it is shorter than ours by ten days, twenty-one hours, and fourteen seconds; consequently the year 1282 of the era of the Hegira began on May 27, 1865.

HEIDELBERG, a city in the Baden circle of Lower Rhine, is situated in one of the most beautiful parts of Germany, on the left bank of the Neckar, in $49^{\circ} 24' N.$ lat., and $8^{\circ} 41' E.$ long., on the Baden and Main-Neckar Railway, 32 miles N.N.E. of Carlsruhe. At the last census the population was 16,288, mostly Protestants. The town is between the river and the mountains which here form the eastern boundary of the valley of the Rhine. From one of these mountains, called Königstuhl (2000 feet high), on the summit of which a lofty tower has been erected, there is a magnificent view of the most beautiful scenery in Germany. The castle, which was the elector palatine's residence, stands on the lower parts of the Königstuhl; it has remained a ruin, but a magnificent one, since 1764, when it was struck by lightning and rendered wholly uninhabitable. In the cellar under it is the celebrated Heidelberg tun, which contains 800 hogsheads, but has not been filled since 1769. The town is chiefly celebrated for its university, which was founded in 1386, and is the oldest in Germany. The university buildings, no way remarkable, stand in a small square in the centre of the town. In a separate building is the university library, which contains 200,000 volumes, and several rare manuscripts. The university is well attended, has forty-five professors, seventy-eight teachers, and an income of 4000*l.*, besides fees. There is also a college for junior students, numerous government elementary schools, botanic gardens, and a museum.

The streets of the town are narrow and gloomy. Among the more remarkable buildings are—the church, dedicated to the Holy Ghost; the interior of which is divided by a partition into two parts, respectively used for Protestant and Catholic worship; the church of St. Peter, the oldest in the town, and memorably connected with Jerome of Prague, who nailed to its door a summary of the reformed doctrine which he preached to a multitude in the churchyard; the Museum Club; the Zum-Ritter Inn, which has a richly decorated façade, and is surmounted by the figure of a knight; and the stone bridge over the Neckar, on which is a statue of the Palatine Karl Theodor. The chief trade of the town is in tobacco and oil; there are breweries and tobacco factories. Wax-lights, leather,

and musical instruments, are also manufactured. The cheapness of living, and the beautiful situation of the town, have caused many foreigners to settle there. Heidelberg was the residence of the electors palatine from the time of Ruprecht I. till 1720, when the electors removed to Mannheim.

HEIGHTS, MEASUREMENT OF. There are three distinct ways by which a height may be measured. The first is by the observed angular elevation of an object, with a measured base [ALTI-TUDE; TRIGONOMETRY]; the second is by means of a spirit-level [LEVELLING]; and the third, which we propose here to describe more particularly, is accomplished by means of the barometer. [BAROMETER.]

If we ascend with a barometer through any height, the weight of the column of air which presses on the instrument is diminished, and the counterpoise, namely, the column of mercury under the vacuum, must diminish likewise; that is, the mercury must fall. Now, if the temperature and force of gravity at the higher and lower station were the same in all places and at all times, one formula would always serve, the height of the barometer remaining the same at the same height above the sea. Even as it is, the mean height of the barometer at the two places, when known, could be made to determine their relative heights. But when only one or two observations can be made at each place, the differences of temperature, &c., must be noted and allowed for.

If the temperature were unaltered during the ascent, and the force of gravity also remained uniform, the *logarithms* of the atmospheric pressures corresponding to different altitudes would *decrease* in arithmetical proportion as the altitudes themselves *increase* in arithmetical proportion; and this would lead to an equation of the form

$$z = c (\log. h - \log. h');$$

where z is the difference of altitudes at two stations, and h and h' the heights of the mercury at the lower and upper stations. This is proved in almost every elementary work on pneumatics.

For very rough estimates of the height z , c is made equal to 10,000 fathoms; and, using the value

of z so found, the term $\frac{n z}{435}$ is then *added to or sub-*

tracted from that value, in order to obtain one more correct: here n denotes the number of degrees of Fahrenheit's thermometer by which the mean temperature of the air *exceeds or falls short of* 31° .

We now proceed to describe a formula for the determination of heights, which is a transformation of the one given in Poisson's 'Traité de Mécanique' (ed. 1833): it supposes that the air intermediate between the higher and lower stations may be treated as if it had throughout the mean between the temperature of the two stations.

Let h and h' be the heights of the barometer at the lower and upper stations; t and t' the temperatures of the air; T and T' those of the mercury (ascertained by a thermometer whose bulb is in the cistern); r the radius of the earth, supposed to be 6,366,198 metres or 6,962,283 yards; and λ the latitude of the place. All the temperatures are in degrees of Fahrenheit. Let

$$k = h \left(1 + \frac{T - T'}{9990} \right)$$

$$c = \frac{20053.95}{1 - 0.002588 \cos. 2\lambda} \left(1 + \frac{t + t' - 64.}{900} \right)$$

$$z = c (\log. h - \log. k).$$

Then z itself is a near approximation to the number of yards in the difference of level between the two stations (for mètres use 18337.46 instead of 20053.95); but if a more exact one be required, it may be found by calculating (using z itself as just found)

$$c \left(\log. h - \log. k + 2 \log. \left(1 + \frac{z}{r} \right) \right) \left(1 + \frac{z}{r} \right).$$

When the lower station is at a great distance from the higher on the earth's surface, then five-eighths of $\frac{z}{r}$ should be used instead of $\frac{z}{r}$ in the last formula.

The preceding is the most accurate formula which the present state of science will allow to be given, and there is reason to suppose that the constant 20053.95 could not be altered by a single unit with any increase of correctness. The following formula, however, is sufficient for ordinary purposes:—

$$20115 \left(1 + \frac{t + t' - 64}{900} \right) (\log. h - \log. k);$$

in which the constant 20115 is that determined by a considerable number of comparisons of theory with trigonometrical observation made by M. Ramond in the Pyrenees. A nearly similar formula has been given by M. Lindenau, with his 'Barometric Tables,' Gotha, 1809.

HEILBRONN. [NECKAR-KREIS.]

HEIR, by the law of England, is he who succeeds by right of blood to the real property or lands, tenements, and hereditaments of the deceased owner, designated by the correlative term of ancestor, not given away from him by will. The English law which determines the succession to personal property, when uncontrolled by local custom, is contained in the Statutes of Distributions (22 and 23 Car. II. c. 10; 29 Car. II. c. 3; and 1 Jac. II. c. 17), which are founded upon the provisions of the civil law. The persons so entitled are not called heirs, but next of kin.

The several rules of descent which regulate the right to succeed to real property spring from the system of feudal tenures, but have been somewhat modified by the recent statute of 3 and 4 Will. IV. c. 106. [DESCENT; FEUDAL SYSTEM.]

Heir, in Scotch law, is a flexible term, and may be applied either to the heir-at-law, or to the heir by destination. It may denote the party who takes the moveable estate, as well as the heir who succeeds to the heritable property. No nomination to be the testator's heir will confer upon the person so appointed any right of succession.

In Roman law, the heir was he who succeeded to the *persona* or whole civil rights of his ancestor. (Dig. L. 17, 128.) There was no distinction between personal and real property acknowledged by that law; and heirs succeeded to both indifferently in certain

proportions, varying in accordance with their relationship to the deceased.

HEIR-APPARENT, in English law, is he whose right of inheritance is indefeasible, as being the eldest son, provided he outlives his ancestor. In Scotch law, he who, after the death of his ancestor, is entitled to enter upon the inheritance, is thus styled before his actual entry.

Heir-*Presumptive*, by the law of England, is he who, if his ancestor should die immediately, would, in the present circumstances, be his heir, but whose right of inheritance may be defeated by the birth of some nearer heir. The eldest brother or nephew of a man who has no children is heir-presumptive. Properly speaking, this term does not occur in Scotch law.

HEIR-LOOMS are such goods and personal chattels as, contrary to the nature of chattels, go to the heir by special custom along with the inheritance, and not to the executor of the last proprietor.

[CHATELS; HEIRSHIP MOVEABLES.]

HEIR-PORTIONER. [HEIRRESS.]

HEIRESS, is a female heir where there are no male heirs to succeed. When there are several sisters equally entitled to property they are called co-heiresses or, legally speaking, co-parceners, in England, and heirs-portioners in Scotland.

Peerages, dignities, and titles of honour descend to the eldest heir-portioner, unless she is excluded from their enjoyment; and she has also right to the mansion-house of a country estate, without making compensation for it to her sisters, but not to a house in town.

HEIRSHIP MOVEABLES, in the law of Scotland, are articles belonging to a deceased proprietor who was a baron, prelate, or burgess, and to which his heir is entitled, though excluded from any share of his ancestor's moveable succession, that he may not enter to his predecessor's dwelling-house quite dismantled by his executors. The heir succeeds without service, but should he die without getting possession they go to the heir of the original proprietor. A list of the articles which form the subjects of heirship is given in the appendix to Sir Thomas Hope's "Minor Practicks," p. 538. They embrace the best articles of furniture in every house belonging to the deceased, articles of farm stock not raised or fed for sale, and generally the best of such subjects as may be necessary to set agoing his establishment. They are the same as heir-looms in English law. [HEIR-LOOMS.]

HEJAZ. [ARABIA.]

HELDER, a fortified maritime town of the Netherlands, in the province of North Holland, at its northern extremity, 41 miles N.N.W. of Amsterdam, with which it communicates by the Helder Canal, 50 miles long, 125 feet broad, and 21 feet deep, enabling ships of large burthen to avoid the navigation of the Zuyder Zee. The town is separated from the island of Texel by the Mars-diep, two miles across. The number of inhabitants in 1862 was 14,751, with a garrison of 9000 men. Near here Van Tromp was killed in action, in 1653. The place was taken by the British, under Abercrombie, in 1799.

HELENA, ST., an island in the Atlantic Ocean, 1200 miles west of the coast of Benguela in South Africa, and 850 from the island of Ascension, the nearest land. Seen at a distance, it appears like a lofty mass of barren rocks rising in a pyramidal

form; on a nearer approach, rugged and almost perpendicular cliffs, from 600 to 1200 feet high, are seen encompassing the island all round, broken through in several places by deep chasms which open to the sea-shore. One of the principal of these openings is called James' Valley, on the north-west coast of the island, and at the opening of it to the sea is James' Town, the only town and port of the island, which is defended by strong batteries, and is the residence of the authorities. James' Town is in $15^{\circ} 55'$ S. lat., and $5^{\circ} 49'$ W. long. It has an excellent harbour, a handsome church, and several good official residences. Ascending James' Valley, we arrive at the plain or table-land of Longwood, situated in the eastern part of the island, and consisting of 1500 acres of fine land, nearly 2000 feet above the sea, sloping gently towards the south-east. Longwood House was the place of Napoleon's confinement and death. It is now in ruins. His remains lay in Geranium Valley till their removal to Paris in 1840; a willow marks the site of the grave. In the centre of the island rises Diana's Peak, 2693 feet high. The circumference of the island is about twenty-eight miles. The population is 7000, of whom one-half are whites. The climate of St. Helena is one of the healthiest under the tropics, and is found beneficial to invalids from India, and even from Europe. Viewed from the sea, the island appears barren; but the interior is covered with a rich verdure, and is watered by abundant springs. Horned cattle, sheep, and goats feed on the rich pastures. The base of the island appears to be basalt, and lava and scorix are found scattered about the surface.

The island was discovered by the Portuguese on St. Helena's day (hence its name) 22nd of May, 1502. It was afterwards taken possession of by the Dutch, who abandoned it in 1651 for the Cape of Good Hope. The English East India Company then took possession of it, and it became a place of call for their ships between India and Europe. It was made over to the British Crown in 1833. It is still visited by ships returning from India for fresh provisions and water.

The exports from St. Helena to the United Kingdom in 1863 were valued at 16,255*l*, and consisted chiefly of cotton, sperm-oil, and sheep-skins. The imports in the same year amounted to 39,550*l*, being principally apparel, haberdashery, leather manufactures, and provisions.

HELEPOLIS, a ponderous movable machine, used by the ancients for besieging towns, forts, &c. It consisted of numerous stories, whose dimensions gradually lessened as they ascended. In each compartment were bodies of soldiers, who discharged their missiles through small openings, previous to making the general assault on the besieged place; while the machine was pushed forward on castors by the strongest men of the whole army.

HELGOLAND, or HELIGOLAND, an island in the German Ocean, about 35 miles from the mouth of the Elbe, consists of a high cliff and a low land united by a rocky isthmus 500 paces in length. The highest part of the cliff rises almost perpendicularly about 200 feet above the sea. The ascent to it is by a flight of 180 steps. The summit is a tolerably level plain about 4200 paces in circumference. The low land, which is almost uninhabited, has two

good harbours. The circumference of the whole island does not exceed three miles. In former ages it was of much greater extent; but the action of the sea is constantly diminishing it, and thus sandbanks are formed all round it. The inhabitants, at the last census 2230 in number, live on the cliff. They are descended from the Frieslanders, and subsist chiefly by fishing, and by acting as pilots. The English took the island from the Danes in 1807, and it was formally ceded to them in 1814. They have erected four batteries and a lighthouse on the cliff, and have a garrison and a governor, but do not interfere with the internal government. The island has of late been much frequented as a watering place. It is of some importance in war time, and is retained by this country at a cost of about 1000*l*. per annum.

HELIACAL ($\%_{\lambda} \iota \epsilon \sigma$, 'the sun'), a term applied to the rising of a star, when it takes place just before that of the sun. If we suppose a star not very far from the sun's orbit, then, as the sun approaches that star, it will become for a season permanently invisible, for it will rise after the sun, and set after it also, the heavens remaining too light in the quarter of sunset to permit the star to be seen. But as soon as the orbital motion of the sun has carried it past the star, the latter will begin to rise first, and in process of time will rise so much before the sun as to become visible just before daylight. In this case it is said to rise heliacally: thus a star sets heliacally before its season of disappearance, and rises heliacally after its reappearance. The successive heliacal risings of stars thus form a continued warning of the seasons, and were used for this purpose among some ancient nations. But since the precession of the equinoxes slowly changes the offices of different stars with respect to the seasons, an ancient record of the time of the year when a given star rose heliacally would enable us to make a rough guess at the number of centuries elapsed since the time of the observation. Upon such a basis Newton rested a great part of his system of chronology, taking the descriptions of the heliacal risings of stars from Hesiod.

HELIAEA, amongst the Athenians, a court of justice, which was next in importance to the Areopagus. It was generally composed of 500 members; and sometimes, in important cases, of more. The judges, in awarding their verdict, made use of black and white beans, which were cast into two distinct urns, and the suffrages numbered before a presiding magistrate, the majority of white beans being equivalent to an acquittal.

HELIANTHEMUM, a genus of plants belonging to the natural order *Cistaceæ* or *Cistaceæ*. There are about 150 species enumerated, which are distributed in various parts of the world: they are chiefly found in the south of Europe, the north of Africa, and a few species in America. *H. guttatum* is an erect herbaceous plant. The flowers are yellow, with a deep red spot at the base of each petal. It is a native of France, Italy, Spain, Portugal, and Turkey. *H. canum*, the hoary sun-rose, has small yellow flowers. It is a native of the south of France and Germany, and rarely found in Britain. *H. vulgare*, the common rock-rose, is a native of Europe, and is found in Britain in dry hilly pastures.

There is a very beautiful variety with double pale yellow flowers, which is much cultivated by florists.

The stamens, if touched in the sunshine, spread slowly, and lie down upon the petals.

Almost all the species of *Helianthemum* are elegant plants, hardy, and easily cultivated.

HELICIDÆ, or *Helix* Family, the general name by which the land Shell-snails are distinguished. This group constitutes part of the 'Pulmonés Terrestres' of Cuvier, the first division of his order *Gasteropoda*. Cuvier divides his Pulmonés, or air-breathing slugs and snails, into the following sections:—

1. *Les Pulmonés Terrestres*—containing the Slugs (*Limacés*), divided into several genera; the Escargots (*Helix*) of which the common Garden-snail is an example, divided into several genera; the Nonpareilles (*Clausilia*); and Agatines (*Achatina*).

2. *Les Pulmonés Aquatiques*—including Les Onchidiées (*Onchidium*), shell-less; Les Planorbis (*Planorbis*); Les Limnées (*Limnæus*); Les Physes (*Physa*); Les Auricules (*Auricula*); and Les Melampes (*Conorulus*).

It is not necessary, in this work, to enter into an analysis of the systems of Lamarck, De Blainville, Rang, and Férussac, nor into the minutæ of genera or species. It will be sufficient to give the following arrangement, by Mr. Gray:—

Terrestrial.

Tentacles retractile. Eyes pedicellate.

Gasteropodous . . . *Limacidae*.

Trachelipodous . . . *Helicidae*.

Aquatic.

Tentacles contractile. Eyes sessile.

Trachelipodous (Mantle thick-edged) *Auriculidae*.

" (Mantle thin-edged) *Limnæadæ*.

Gasteropodous (Mantle shield-like) *Onchidiadæ*.

Cuvier observes that 'the Pulmonifera are distinguished from other molluscs; that they respire the elastic air by means of an orifice under the edge of the mantle, which they dilate or contract at pleasure; they have therefore no branchiæ, but only a network of pulmonary vessels which spreads itself upon the walls, and principally upon the ceiling of the respiratory cavity; some are terrestrial, others live in the water, but are obliged to come from time to time to the surface, and open the orifice of their respiratory cavity in order to respire. All these animals are hermaphrodites. Almost all the terrestrial pulmonifera have four tentacles; two or three only, of small size, do not exhibit the inferior pair.'

Under the *Helicidæ* are comprehended the genera *Helix*, *Carcocolla*, *Vitrina*, *Anostoma*, *Helicina*, *Bulinus*, *Pupa*, *Clausilia*, *Achatina*, *Auricula*, *Cyclostoma*, *Pedipes*, *Chondrus*, *Succinea*, &c. In *Auricula* and *Cyclostoma* the tentacles are only two.

Having thus endeavoured to explain the position of the *Helicidæ*, of which the large Garden-snail (*Helix aspersa*) is an example, we may proceed to give a brief and general outline of the more important parts of their organic economy as seen in the restricted genus *Helix*.

Nutrient Organs.—The mouth is transverse, and a portion of it is destined to perform the office of teeth. The margin of the upper lip is dentated, and of a horny texture, of a dark colour and arched form; the lower lip is divided by a vertical fissure. The salivary glands are of a conglomerate structure, and lie on the parietes of the stomach.

Respiratory System.—The pulmonary sac receives the air by an anterior orifice on the right side of the neck; and the reticulation of the pulmonary artery, or continuation of the veins of the body, ramifies on its roof.

Brain, Nervous System, and Senses.—A ganglion well developed, situated above the œsophagus, of a transverse shape, supplies the antennæ and the eyes with nerves; this ganglion forms a ring, completed by a larger ganglion below the œsophagus, from which numerous nerves radiate to supply the body. A small ganglion is formed on the nerve which supplies the heart and respiratory apparatus. The sense of touch resides especially in the ventral disc or foot, and in the lower tentacles.

The eyes are situated on the side of the posterior tentacles or horns, at their extremity. In this position, though destitute of appropriate muscles, the eyes have the advantage of all the mobility with which the tentacle itself is endowed; and by the admirable construction of the same part, they are defended from external injury by being retracted and inverted, together with the extremity on which they are supported, within the cavity of the tentacle, as in a sheath.

The taste appears to be sufficiently acute, nor is the sense of smell absent, though we know not by what particular organ it is exercised. Slugs and snails are attracted towards their favourite food, as is well known to the gardener.

No organs of hearing have been detected, nor do they appear to enjoy this sense.

Reproduction.—Shell-snails are hermaphrodites, but fecundate each other by mutual union. The situation of the reproductive organs is at the anterior orifice of the neck. Most are oviparous, but some are viviparous. The shells, as a general rule, are either round and enveloped in a skin, as in the common garden-snail, or oval and inclosed in a hard calcareous shell, as in *Achatina* and *Bulinus* (or *Bulinus*). [BULINUS.]

Power of Repairing Injuries.—The power which snails, in common with other testaceous molluscs, possess of repairing their shells, is known to most observers, and requires no comment; but the extent to which these animals will repair lesions of the soft parts, and even reproduce some of the principal ones after they have been deprived of them, is deserving of notice. The works of Schoeffer, Spallanzani, Bonnet, and others, bear testimony to the wonderful *vis vitæ* in these animals, and its energy in replacing parts, the deprivation of some of which must, it might have been previously thought, have been followed by immediate death. Spallanzani cut off one of a snail's horns: it began to bud again in about twenty-five days, and continued to grow till it was equal in length to the other. He removed part of the head: in course of time the part was renewed. Not that this was always the case in those instances where the entire head had been taken off; but even in these instances the snail often recovered, and at the end of a few months appeared with a new head in all respects equal to the old one. The whole of Spallanzani's experiments have been confirmed by Gerardi and others.

Hybernation.—In our temperate climate, as soon as the chills of autumn are felt, the shell-snails begin

to withdraw to winter quarters and prepare for their annual repose. They either burrow into the earth, attach themselves to sheltered crevices in walls, congregate under accumulations of garden-pots in the gardener's tool-house, or in corners of the garden, under the roots of hedgerow-trees, under the moss of banks, and in various other places of refuge. By means of the secreted mucus they adhere to whatever object they fix upon for attachment, and, besides this, throw a temporary operculum like a drum-head over the mouth of their shell. This operculum consists of several layers, with air between each; and this air, on the reviviscence of the snail in spring, as layer after layer is broken down, serves the necessities of the pulmonic system, till the last layer (or that first formed) is demolished.

Geographical Distribution and Habits.—The *Helicidae* are most widely diffused over the surface of the earth; scarcely any countries but those where the climate is surpassingly rigorous are without some species of the family. Many of the shells are strikingly beautiful in form and colour, and these are mostly the inhabitants of intertropical countries. Some of the genera (*Achatina*, for instance) attain a very large size, and lay eggs in proportion. *Helix aspersa*, the common garden-snail, is distributed over a large portion of the globe. It is found, for instance, at the foot of Chimborazo, in the forests of Guyana and Brazil, and on all the coasts of the Mediterranean in Europe, Asia, and Africa. *Helix pomatia* has been naturalized with us. The first importation is attributed by some to Sir Kenelm Digby. Merrett mentions it as a British inhabitant before his time. A moist and rather warm state of the atmosphere seems most congenial to this family. To avoid much dry heat, they get under stones, under old trunks of trees, leaves, &c., &c., and some of the species will burrow into the earth for protection against it. A shower will bring them forth in such numbers sometimes, the smaller species especially, as to induce the belief in some cases that it has been raining snails. Most of the species hibernate.

Utility to Man.—The *Helicidae*, from their voracity, are very injurious to the agriculturist and horticulturist; but there can be no doubt that the larger species are good food. We know that they were a favourite dish with the Romans, who had their *cochlearia*, where they were regularly fattened with new wine boiled down and meal (*sapa et furre*, &c.) (Pliny, 'Hist.' lib. ix., c. 56.) *Helix pomatia* is used as food in many parts of Europe during Lent, and the snails are kept in an *escargotoire* (snailery), which is generally a large place boarded in, having the floor covered half a foot deep with herbs, where the animals fatten. Many are familiar with the passage referred to in Pliny, who, on the authority of Varro, relates the incredible size to which the art of fattening had brought the snails. [See Plate 'Helix,' for several representative forms of *Helicidae*.]

Fossil Helicidae.—Fossil species of *Helicidae* number between fifty and sixty species, which occur only in the Tertiary.

HELICTIS, Mr. Gray's name for a genus of quadrupeds which inhabit eastern Asia, and has the general appearance and colouring of *Mydatis*, combined with a dentition resembling that of *Gulo* or *Mustela*, but differing from both the latter genera in the large

internal central lobe of the upper carnivorous tooth. The genus is thus characterized by Mr. Gray:—

Incisors, $\frac{6}{6}$; Canines, $\frac{1-1}{1-1}$; Molars, $\frac{5-6}{5-6}$.

Head elongated. Feet short; soles of the feet nearly naked to the heel; toes 5—5; claws strong, the anterior ones long and compressed. Tail cylindrical and moderate.

Mr. Gray exhibited to the Zoological Society one species, *Helictis moschata*, the entire length of which was twenty-three and a half inches, of which the tail measured eight. Inhabits China, and smells strongly of musk. For further particulars see 'Zool. Proc.' 1831.

HELIER, ST. [**JERSEY.**]

HELIGOLAND. [**HELGOLAND.**]

HELIOCENTRIC (having the sun as centre), a term applied to the place of a planet, as seen from the centre of the sun, in opposition to its *geocentric* place, as seen from the centre of the earth.

HELIODORUS was born at Emesa in Syria, in the fourth century of the Christian era. He was bishop of Tricca in Thessaly. He wrote in his youth a romance in the Greek language entitled 'Ethiopia,' which contains an account of the wonderful adventures of two lovers, Chariclea, the daughter of Hydaspes, king of Ethiopia, and Theagenes, a noble Thessalian. The work of Heliodorus served as a kind of model to the subsequent Greek writers of romance. The best edition is by Coray, 2 vols. 8vo., Paris, 1804. The 'Ethiopia' has been translated into most modern European languages. There is an English translation by Underdown, 1587 4to.; and by others.

HELIOGABALUS. [**ELAGABALUS.**]

HELIO/METER (ἥλιος, 'the sun,' and μέτρον, 'measure') is the name given by M. Bouguer to a micrometer invented by himself about 1745, by means of which the diameter of the sun, or any other heavenly body, may be measured with considerable accuracy. The name is also given to the equatorially mounted micrometer executed at Munich in 1829 for the Königsberg Observatory. [**MICROMETER.**]

HELIO/POLIS. [**BAALBEC.**]

HELIO/PORA, a genus of stony Polyparia, established by De Blainville, from observations of MM. Quoy and Gaimard on a recent species called by Lamarck *Pocillopora cœrulea*.

Generic Character.—Animals short and cylindrical, provided with a simple circle of thick tentacula, fifteen or sixteen in number, contained in vertical or diverging cylindrical cells; cells immersed, internally crenulated by imperfect radiating lamellæ, united into a calcareous mass, which is regularly porous in the intervals of the cells. The coral is found attached to various bodies. Three recent species are mentioned by De Blainville, all from warm seas. One of the fossil species (*Heliopora porosa*, De Blainville; *H. interstincta*, Bronn) abounds in strata of the Silurian system; others occur in the chalk and in tertiary deposits.

HE/LIOSCOPE (a Greek term signifying literally 'sun-observer') is a kind of telescope adapted for making observations upon the sun without the eye being injured by the intense brightness of the solar

rays. A coloured glass placed before the lens nearest to the eye, in a telescope, has long been the means used to prevent such injury.

HELIOSTAT (ἥλιος, 'the sun,' and the root *στα*, *sta*, 'to put or place') is the name given to an instrument employed in making optical experiments on the physical properties of light. The instrument consists of a plane metallic mirror, from the back of which projects a rod perpendicularly to its plane. The extremity of the rod is connected with the index of a clock, the plane of whose face is parallel to the equator; and as the index is turned by the wheel-work, the motion of the rod causes the mirror to turn about a vertical axis, and also about a horizontal axis, so that a pencil of the sun's light reflected from the mirror is always in the same position. (Biot's *Physique Experimentale*.)

HELIOTROPE (Gr. *helios*, 'the sun,' and *trepho*, 'to turn'), a silicious mineral of a deep green colour, and sometimes variegated with blood-red spots, whence it is known as the Bloodstone.

HELIOTROPICUM, a genus of plants belonging to the natural order *Ehretiaceae*. *H. Peruvianum*, Peruvian heliotrope or turnsole, is a shrub, growing one or two feet high, and is much cultivated on account of the scent of its flowers, which resembles very much that of the vanilla. It is a native of Peru. *H. Europæum*, the European turnsole or heliotrope, is a native of the south of Europe and the regions of the Caucasus. The flowers are sweet-scented. *H. villosum* is a native of Greece and of the islands of the Archipelago. It has large white corollas with a yellow throat.

Upwards of eighty species of this genus have been enumerated. Some of them are consumed in large quantities by perfumers for the sake of their volatile oil. They are astringent and also mucilaginous, and poultices made of the leaves have been applied to cancerous and scrofulous sores.

HELL (Greek, *Hades*; Heb. *Sheol*; German, *Hölle*). In theology this word refers to the scene or place or condition of punishment of the wicked after death. Nearly all religions, ancient and modern, hold the belief in hell, though they differ as to the place, nature, and duration of it. The belief in the eternity of the punishments of hell has been the common doctrine of both the Eastern and Western Churches; but since the time of Origen there have been some who taught that the duration is proportioned to the guilt, and that the infliction is remedial, only to last till its purifying effect is attained. Certain passages of Scripture, if taken literally, will not allow of this interpretation (Matt. xviii. 8; xxv. 41 and 46; Mark ix. 43; Luke iii. 17; 2 Thess. i. 9), but many attempt to explain these passages in such a way as to accord with this view.

Both the above-mentioned churches also agree that the punishment of hell includes not only material pain, but also the remorseful consciousness of having forfeited the presence of God and the happiness of heaven.

The word hell is sometimes applied in Scripture to the grave.

HELL, MAXIMILIAN, a distinguished astronomer and member of the order of Jesuits, was born May 15, 1720, at Schemnitz in Hungary, and manifested, at an early age, a decided taste for the study

of natural philosophy and astronomy. At twenty-five years of age he was employed as an assistant in an observatory belonging to the Jesuits at Vienna, and he was at the same time keeper of the museum of experimental philosophy which had just then been formed in that city. After residing some years in Hungary and Transylvania, he returned, in 1758, to Vienna, where he was established in an observatory which had been built in conformity to his own directions; and he held the appointment during the remainder of his life.

Through the mediation of Count Bachoff, who was sent from Copenhagen for the purpose of making the proposal, he accepted an invitation from the court of Denmark to undertake a journey to Wardhuys in Lapland, in order to observe there the transit of Venus over the sun's disc. Accordingly, he set out from Vienna in 1768; and, after staying a short time at Copenhagen, he proceeded to the place of his destination: he was absent about two years and a half on that mission, when, having fully succeeded in its object, he returned to Vienna. Besides observing the transit, Hell took advantage of his residence in Lapland to study the geography, the natural history, and the climate of the country; the history, language, and religion of the people, with the state of the arts among them. He made also numerous observations on terrestrial magnetism, on the phenomena of the tides and winds, and on the variations of the barometrical column; and he measured the heights of the principal mountains.

The principal work published by this astronomer was a series of Ephemerides in thirty-five volumes 8vo., the collection being entitled 'Ephemerides anni 1757—1791 ad Meridianum Vindobonensem Calculis definitæ.' He published an edition of the Solar Tables of La Caille, and the Lunar Tables of Mayer, with supplements: he also published his celestial observations in Lapland, under the title 'De Transitu Veneris ante discum Solis die 3 Junii, 1769, Wardohusii observato,' 1770; and a work entitled 'De Parallaxi Solis ex Observationibus Transitus Veneris, anni 1769,' 1773.

Hell died at Vienna, April 14, 1792.

HELLANICUS, one of the early Greek prose writers, was born at Mitylène in the island of Lesbos, B.C. 496. He wrote several historical works, which are frequently quoted by ancient writers. Hellanicus is mentioned by Thucydides (i. 97). The fragments of Hellanicus were published by Sturz, 8vo., Leipzig, 1787; 2nd edition, 1826.

HELLEBORE, WHITE. [*VERATRUM ALBUM*.]

HELLEBORUS, a genus of exogenous plants belonging to the natural order *Ranunculaceae*. The most remarkable species is that which produced the black hellebore, a dangerous acrid poison, much used by the ancient Greek physicians in mania, epilepsy, and dropsy.

Helleborus orientalis has been substituted in the Pharmacopœia for the *Helleborus niger*, from a belief that it is more powerful. It is a perennial species, growing in mountainous places in the East. The root, which is the part employed, is black: it is extremely acrid. It is to be regretted that many other roots, especially those of *Actæa spicata* and *Adonis vernalis* are often intentionally or accidentally sold instead of the root of *Helleborus niger*. These

may be discriminated by physical characters (particularly the internal structure) and by chemical tests.

Like most ranunculaceous plants, hellebore occasions rubefaction and inflammation of any surface with which it is brought in contact. When taken into the stomach in a moderate dose, it gently stimulates it and the other viscera of the abdomen; but in large doses it is a fatal poison.

HELLENES. [GREECE.]

HELLENIST, is a Jew who uses the Greek language, and in other forms allies himself to the Greek nation. Hellenes is the name of the real Greeks, and the term Hellenist was given to those Jews who by birth or residence, and by adopting the manners and customs of Greece, were looked upon as Greeks. Soon after the commencement of the Christian era, the Jews were dispersed all over the Roman empire; but it was to those settled in Alexandria that the term Hellenist chiefly applies. Here the Hellenistic philosophy had its rise, and the dialect of Greek called Hellenistic, in which the Septuagint is written, was formed.

HELLESPOINT. [DARDANELLES.]

HELM, the steering apparatus of a ship, consisting of the rudder, the tiller, and the wheel. The rudder is the part acting directly on the water, and serves to govern the ship's motion; for, on being turned so that its plane is in a position oblique to the plane of the masts and keel, the reaction of the water against it, as the ship advances, being resolved in a direction perpendicular to the last-mentioned plane, becomes a force which causes a ship to turn upon a line passing through its centre of gravity. The tiller is a lever, formed into a handle, for multiplying the power exerted on the rudder. The wheel moves the long end of the tiller from side to side of the vessel, by means of ropes or chains, still further multiplying the power of the leverage. In small vessels and barges the wheel is dispensed with, and the tiller used without its assistance.

HELMET, an ancient armour of defence for the head, still worn by the officers and soldiers of some of our cavalry regiments. As a part of defensive armour, the helmet is of high antiquity; some sort of covering of this description for the head appears to have been worn by the warriors of every country. Helmets were found even among the inhabitants of the South Sea Islands when discovered by Captain Cook.

It does not appear that the Greek or Roman helmet usually protected the face. Among the varieties which had separate names we find the *Chapelle de Fer*, the *Bacinet*, the *Burgonet*, the *Castle*, the *Hufen*, the *Morion*, the *Salade*, and the *Skull*. These were almost invariably of steel. There was also the *Jousting Helmet*, used in tournaments, which was sometimes of leather.

Firemen of the present day wear a heavy head-piece of leather and brass, to protect them as far as possible from falling ruins at conflagrations; and the police of London have recently (1865) been supplied with a somewhat similar covering for the head. In India, and other hot climates, helmets of white felt, with the additional screen of rolls of white linen, are constantly worn by military men, to protect them from the rays of the sun.

As ornaments over the shield or coat of arms,

helmets are still used in heraldry. The full-faced helmet with six bars, all of gold, damasked, is for the sovereign and princes of the blood; the full-faced helmet of steel, for marquises and dukes; earls, viscounts, and barons have a profile or side-standing helmet of steel ornamented with bars; the full-faced helmet of steel, with the visor or beaver open, is for baronets and knights; the profile helmet, steel, with the visor closed, for an esquire.

HELMONT, VAN. [CHEMISTRY.]

HELMSTEDT. [BRUNSWICK.]

HELOISE. [ABELARD.]

HELOPIDÆ (Leach), a family of coleopterous insects of the section *Heteromera* and sub-section *Stenelytra*. Head short, obtusely terminated anteriorly; mandibles notched at the apex; antennæ placed near the eyes, generally filiform, or nearly so, or slightly thickened at the apex, where the joints are short; the basal joint of the antennæ hidden above by a projected margin of the head; the third joint long; terminal joint of the maxillary palpi large and securiform; eyes emarginated anteriorly; legs moderate; the penultimate joint of the tarsi generally simple or but slightly emarginated; claws simple; body usually convex, and of an oval form.

The larvæ of these insects live in rotten wood, upon which they feed; they are of a cylindrical form, hard to the touch, and have six small legs, attached two to each of the thoracic segments. The perfect insects are, like the larvæ, also found in rotten wood, or under the bark of trees; they are rather slow in their movements, and generally adorned with metallic colours.

HELOSCIA'DIUM, a genus of plants belonging to the natural order *Umbelliferae*, and to the tribe *Ammineæ*. There are three British species of this genus, *H. nodiflorum*, *H. repens*, and *H. inundatum*. The first is a native of brooks and ditches, and is frequently mistaken for the water-cress. The second is a rare plant in Great Britain. The last species is found in ponds.

HELOSTOMA, a genus of fishes, of the family *Spirobranchide*, with ovate bodies, the ventral fins rounded, and the mouth small, and very retractile.

HELOTES, a genus of fishes, of the family *Percidæ*, with fusiform body, small mouth, and obtuse snout.

HELOTS. [SPARTA.]

HELSINGFORS. [FINLAND.]

HELSTON. [CORNWALL.]

HELVELLA. [HYMENOMYCETES.]

HELVELLYN. [CUMBERLAND.]

HELVETIC ALPS. [ALPS.]

HELVETII, a race which formerly inhabited a part of Europe corresponding to modern Switzerland. We learn from Cæsar that they had twelve towns and 400 modern villages, all of which they burned in the year 58 B.C., previous to their attempted invasion of Southern Gaul, to prevent which Cæsar had to destroy the bridge at Geneva, and to build a long wall along the Rhone. Failing to pass this barrier, the Helvetii took another route, but were met and repulsed, two-thirds of their number being slaughtered, and the remainder obliged to return to their own country, and subject themselves to the Romans. After the death of Nero they gradually became extinct as a race.

HELVETIUS, CLAUDE-ADRIEN, was born at Paris in January, 1715, and was educated at the Jesuits' College of Louis le Grand. Having passed through a course of legal study, Helvetius obtained the lucrative appointment of *fermier-général*, through the influence of the queen, Marie Leczinsky, to whom his father was physician. But disgusted with the oppressive nature of its duties, he resigned this situation, and purchased that of chamberlain to the queen's household. At this period Helvetius led a disorderly life; and vanity was a conspicuous feature in his character. But Helvetius was as kind-hearted as he was vain, and an act of beneficence was as dear to him for its own sake as the applause which he courted so eagerly.

In 1751 Helvetius married the beautiful and accomplished daughter of the Comte de Ligneville. From this time he lived chiefly in retirement at Voré, enjoying with his wife and children the pleasures of domestic life, and ameliorating the condition of his tenants and vassals. In 1758 he published the treatise 'De l'Esprit,' which was denounced by the court and the Jesuits as dangerous to society and to religion. To regain the favour of the court, Helvetius published three letters of apology. Notwithstanding his confession of a Christian faith, and his disclaimer of all opinions inconsistent with its spirit, the doctors of the Sorbonne drew up a formal condemnation of the work; and it was publicly burned, according to a decree of the parliament of Paris. The style of the work is vicious and declamatory, but the argument is well sustained, and enforced by great felicity and copiousness of illustration. In 1764 Helvetius visited England. He died at Paris, 26th December, 1771, leaving behind him a work entitled 'De l'Homme, de ses Facultés et de son Education,' which was published the same year at London by Prince Gallitzin. This treatise, which may be considered as a continuation of and commentary upon his earlier philosophical work, is vastly superior to it in style.

HELVIN, a crystallized mineral, of which the primary form is a cube, and the colour a greenish yellow. It consists chiefly of silica, protoxide of manganese, and sulphuret of manganese.

HELVOETSLUYS. [HOLLAND.]

HEMANS, FELICIA DOROTHEA, was born September 25, 1794, at Liverpool, where her father, whose name was Browne, was engaged in mercantile pursuits. He was a native of Ireland; her mother was an Englishwoman, but was descended from a Venetian family, through her father, who was the commercial agent at Liverpool for the Venetian government. About the year 1800 Mr. Browne, in consequence of the failure of a mercantile concern, removed his family from Liverpool to an old mansion, spacious and solitary, called Grwyeh, not far from Abergelge, in Denbighshire, North Wales. Mr. Browne died not long afterwards. Felicia Browne began to write poetry before she was nine years of age. Her first volume of poems was published in 1808, and contains some verses written by her as early as 1803 or 1804. A harsh review of this little volume affected her so much that she was confined to her bed for several days. Her second volume, 'The Domestic Affections,' was published in 1812.

In 1812 Miss Browne became the wife of Captain

Hemans, of the 4th regiment. His constitution had suffered so severely in the retreat upon Corunna, and subsequently by fever caught in the disastrous Walcheren expedition, that he felt it necessary, a few years after their marriage, to exchange his native climate for that of Italy. This at least is the motive assigned for his leaving his wife; but their union, it is said, was not happy, and this separation, which took place just before the birth of her fifth son, closed it for ever. Mrs. Hemans, with her five sons, went to reside with her mother, then living at Bronwylfa, near St. Asaph, in North Wales.

Mrs. Hemans now resumed her literary and poetical pursuits with increased ardour. She studied the Latin, Italian, Spanish, Portuguese, and German languages. She made some translations from Horace, Herrera, and Camöens, and contributed a series of papers on Foreign Literature to the *Edinburgh Magazine*. 'The Restoration of the Works of Art to Italy' was published in 1815; 'Tales and Historic Scenes,' in 1819; and, about the same time, 'The Septic,' a didactic poem, in heroic rhyme; and 'Modern Greece,' in ten-line stanzas. Her poem of 'Dartmoor' obtained the prize from the Royal Society of Literature in 1821. Her tragedy, 'The Vespers of Palermo,' was represented at Covent Garden Theatre, London, in 1823. It was unsuccessful there, but was afterwards better received at Edinburgh, when Sir Walter Scott wrote an epilogue for it. 'The Siege of Valencia,' 'The Last Constantine,' and other Poems, were published in 1823.

In 1825 Mrs. Hemans removed, with her mother, her sister, and her two sons, to Rhyllon, near St. Asaph. Her sister had returned, in 1821, from Germany, where one of her brothers was attached to the Vienna embassy, bringing with her a fresh supply of German books, and Mrs. Hemans' delight in German literature may be dated from that time. Her 'Lays of many Lands,' most of which appeared in the *New Monthly Magazine*, then edited by Thomas Campbell, were suggested by Herder's 'Stimmen der Völker in Liedern,' and, preceded by 'The Forest Sanctuary,' formed her next volume, published in 1827, which was followed, in 1828, by the 'Records of Woman.'

In the autumn of 1828 Mrs. Hemans established herself at the village of Wavertree, near Liverpool, and in 1830 she published 'The Songs of the Affections.'

In the spring of 1831 Mrs. Hemans left England for Dublin, where she took lodgings. Her health, from the time of her leaving England, became rapidly worse.

The latter months of 1833 were busily spent in arranging and preparing for publication the three collections of her poems which were published in the spring and summer of 1834; 'Hymns for Childhood,' 'National Lyrics and Songs for Music,' and 'Scenes and Hymns of Life.'

In August, 1834, Mrs. Hemans was attacked with scarlet fever, and, when imperfectly recovered, caught a cold; ague was superinduced, and never left her till it was subdued by her last fatal malady, dropsy. On the 26th of April, 1835, Mrs. Hemans dictated her last poetical effort, the 'Sabbath Sonnet.' She continued to sink gradually till May 12 of the same year, when she died. She was buried in St. Anne's

Church, Dawson Street, Dublin. A volume of 'Poetical Remains' was published after her death.

HEMATIN, the colouring matter of the *Hæmatoxylon campechianum*, or logwood. It appears in small crystalline laminae of a reddish colour. It is decomposed by heat, and is soluble in water, where its colour changes to orange and yellow.

HEMATOSIN, the red colouring matter of the blood. It has not, however, been obtained in a perfectly pure state, owing to the difficulty of separating it from other substances, and to the facility with which it undergoes change. A peculiarity of hematosin is its containing oxide of iron, which does not occur in other parts of the animal system. The hematosin of bullocks' blood, but not quite pure, for the reasons already stated, analyzed by Mulder, yielded the following ingredients:—

Carbon, ...	66.49
Azote, ...	10.54
Hydrogen, ...	5.30
Oxygen, ...	11.01
Iron, ...	6.66

100.

HEMEL HEMPSTEAD. [HERTFORDSHIRE.]

HEMERALOPIA, a word which is now used to signify 'night-blindness,' though in fact it means 'day-seeing,' being similarly formed to the genuine Greek word 'nyctalopia' (νυκταλωπία), which means 'night-seeing.'

Night-blindness is a common disease amongst seamen in the East and West Indies, the Mediterranean, and in all hot countries, and affects in a slighter degree soldiers and the natives in the same parts of the globe. To persons affected by it all objects appear at sunset as if covered with an ash-coloured veil, which becomes gradually denser, and at last involves them in complete darkness. In slight cases they can see by bright candle-light or by moon-light; but after the disease has lasted a few days, even the largest objects are invisible after sunset, and the patients have to grope their way even where the moon or candle is shining brightly. The pupils are generally dilated, and at night cannot be made to contract even by a brilliant light.

The disease will generally disappear, though it may exist for weeks or months. The most successful treatment is the repeated application of small blisters to the temples.

Nyctalopia, night-vision, or day-blindness, probably never occurs as a separate disease. It is often a symptom of scrofulous ophthalmia and other diseases, where the eye is so irritable that the stimulus of daylight cannot be borne, as well as of those conditions in which great dilatation of the pupil is requisite for vision, as in incipient cataract, or opacity of the centre of the lens or its capsule.

HEMEROBAPTISTS (Gr. *hemera*, 'a day,' and *bapto*, 'to wash'), an ancient Jewish sect, mentioned by Epiphanius, who were so called from their washing and bathing every day in all seasons. Like the Sadducees they denied the resurrection of the dead; but in other points they held nearly the same opinions as the scribes and Pharisees.

HEMEROBIUS, a genus of insects of the order *Neuroptera* and section *Planipennes*. The genus, as

established by Linnæus, has been dismembered by subsequent entomologists, and is now equivalent to a family distinguished by the filiform antennæ and by the number (four) of the palpi of the insects included in it. They have soft slender bodies, much exceeded in length by the large reticulated wings, which, when the animal is at rest, are deflexed. Their eyes are globular and vividly metallic. The larvæ are ferocious in habit, and prey upon plant lice, seizing them with their powerful jaws, and sucking them to death. When full grown, they spin, and envelope themselves in a silken cocoon. The eggs of *Hemerobii* are deposited on plants, and are pedunculated, so as to resemble fungi, for which they have sometimes been mistaken. These insects range from Europe to Australia, and there are many species natives of the British Isles.

HEMEROCAL/LEÆ (Gr. *hemera*, 'a day,' and *kalos*, 'beautiful'), a tribe of *Liliaceæ*, or Day-lilies, with campanulate corollas, and assimilating in many respects to the *Tulipeæ*, or Tulips.

HEMI ('half'), a Greek particle, is very generally used as a prefix in the composition of words connected with natural science, and is usually found expressive of the form or nature of the object to be described; as *Hemicircus* (half-hawk), a genus of birds of the horned owl kind, and of the family *Strigidæ*; *Hemicycla* (half-round), a genus of *Helicina*, or land-snails, with a discoid shell, and four whorls; *Hemidactylos* (half-fingered), a genus of Saurian reptiles, of the family *Iguanidæ*, and belonging to the flat-toed lizards; *Hemidon* (half-toothed), a genus of *Mollusca*, of the family *Unionidæ*, and belonging to the *Anadonts*, in which the shell is ovate; *Hemifusus* (half-spindle), a genus of *Mollusca* of the family *Turbinellidæ*, and belonging to the *Fusina*, or Spindle shells, in which the shell is unequal or half-fusiform; *Hemilepidotus* (half-scaled), a genus of fishes of the family *Cottidæ*; *Hemilophus* (half-crested), a genus of birds of the family *Picidæ*, and belonging to the *Picina*, or Woodpeckers; *Hemionite* (a mule or half ass), a genus of *Ferns*, of the order *Polypodiaceæ*; *Hemipeplus* (half-veiled), a genus of coleopterous insects, of the family *Melasma*; *Hemipodius* (half-footed), a genus of birds of the Grouse kind, and of the family *Tetronidæ*; *Hemirhamphus* (half-snouted), a genus of fishes of the family *Salmonidæ*, and belonging to the Flying fishes, in which the upper jaw is long, and the lower one short; *Hemisinus* (half-channelled), a genus of *Mollusca*, of the family *Turbidæ*; *Hemisphæra* (half a globe), in astronomy and geography, one half of the mundane sphere, the equator dividing it (north and south) into two equal parts; *Hemirochus* (half-topped), a genus of *Mollusca*, the shells of which have convex whorls and conic spires.

HEMICARDIUM (Gr. *hemi*, 'half,' and *kardia*, 'heart'), a sub-genus of *Mollusca*, of the family *Tellinidæ*, and sub-family *Venerinæ*. The shell is half heart-shaped (whence its name), and the anterior side abruptly truncated.

HEMICIDARIS, a genus of fossil *Echinodermata*, from the oolite.

HEMIOPIA (from *ἡμί*, 'half,' and *ὄψις*, 'the eye') is a disease in which the patient sees only a part of the object he looks at; the middle of it, or its circumference, or its upper or lower part, or

more commonly one lateral half, being completely obscured.

HEMIPNEUSTES, a genus of fossil *Echinodermata*, from the chalk marl.

HEMIPTERA (from *hēmi*, 'half,' and *ptērōn*, 'a wing'), one of the orders of the class *Insecta*.

The order *Hemiptera*, according to the twelfth edition of the 'Systema Naturæ' of Linnæus, contains insects which agree in having incomplete metamorphoses (i.e., the larva and pupa both possess the power of locomotion, and bear a great resemblance to the perfect insect), and also in having the superior wings generally coriaceous, and the inferior membranous. Thus Linnæus included in this order the Cockroaches, Locusts, Grasshoppers, Bugs, Cicadæ, &c. The last-mentioned insects, the Bugs and Cicadæ, however, differ very materially from the former, inasmuch as they possess a suctorial instead of a masticatory mouth; and as these latter characters have been considered of great importance by all the more modern entomologists, the term *Hemiptera* has been restricted to such insects as have imperfect metamorphoses and a suctorial mouth.

This definition will include the Linnæan genera *Fulgoria*, *Cicada*, *Notonecta*, *Nepa*, *Cimex*, *Aphis*, *Chermes*, *Coccus*, and *Thrips*, and these, with the addition of the genus *Pulex*, constitute the order to which Fabricius applies the name of *Ryngota*. Without the last-mentioned genus they constitute the order *Hemiptera*, according to Latreille, Burmeister, and most of the foreign entomologists; and the orders *Hemiptera* and *Homoptera*, according to Leach, Stephens, MacLeay, and several other British authors.

The *Hemiptera* are divided by Latreille into two sections; to the first he applies the name of *Heteroptera*, and to the second that of *Homoptera*. The *Heteroptera* are characterized by having the rostrum attached to the fore part of the head; the elytra coriaceous with the extremity membranous, folding one over the other when at rest; and the first segment of the trunk (or the prothorax) the largest, and forming the most conspicuous part of the thorax. The second section, *Homoptera* (which by many of the English entomologists is regarded as an order), is distinguished by the proboscis being attached to the lower portion of the head, near the chest; the elytra almost always of a uniform coriaceous texture, with their inner margin straight and contiguous; the three segments of the thorax are united in a mass, and the first is frequently shorter than the second. All the insects of this section feed exclusively on vegetable juices. [HOMOPTERA.] We shall at present confine our remarks to the first section, or to the true hemipterous insects, or *Heteroptera*.

The *Heteroptera* are divided by Latreille into two families; the first, or the *Geocorisæ*, are characterized as having the antennæ free, longer than the head, and inserted between the eyes and near their anterior margin. The tarsi are three-jointed, but the first joint is sometimes very short. The second family, to which the name of *Hydrocorisæ* is applied, have the antennæ inclosed and hidden in a groove beneath the eye; the tarsi have but two distinct joints, and the eyes are generally very large.

The species of the family *Geocorisæ* are for the most part found on the leaves of trees or small plants;

VOL. VII.

some there are which do not quit the ground, and there are others which live upon the surface of the water. The genera *Hydrometra*, *Gerris*, and *Velia*, afford examples of this last mode of life.

The insects belonging to the second family (*Hydrocorisæ*) live, as their name implies, in the water, and they prey upon other insects.

The two families which have just been characterized are by most entomologists regarded as sections or subsections rather than families; the latter is in fact an aberrant group, the former containing by far the greater portion of the species. Regarding them therefore as sections, they may be divided into the following families:—

Geocorisæ.

- | | |
|-------------------------|---------------------|
| Family 1. Scutelleridæ. | Family 5. Cimicidæ. |
| 2. Pentatomidæ. | 6. Reduviidæ. |
| 3. Coreidæ. | 7. Hydrometridæ. |
| 4. Acanthiidæ. | |

Hydrocorisæ.

- | | |
|-------------------|------------------------|
| Family 1. Nepidæ. | Family 2. Notonectidæ. |
|-------------------|------------------------|

HEMISPHERE, the half of a sphere. [SPHERE.]

HEMITONE, an interval in ancient music, the ratio of which is $\frac{243}{256}$.

HEMI'TRYPA, a genus of fossil *Polypiarina*, in the limestone of Devonshire, allied to *Fenestella*. (Phillips.)

HEMLING, HANS. [MEMLING.]

HEMLOCK. [CONIUM MACULATUM.]

HEMP, a genus of plants, the botanical name of which is *Cannabis*. It is a native of Asia, but is now naturalized in Europe and America. It varies in height from four to twenty feet, and is an elegant plant. The flowers are small and numerous, and of a yellow-green colour. Hemp is cultivated chiefly for its fibre, and the seed is sown at a season when the plants are likely to grow very rapidly, in order to form long fibres. When a fine fibre is required, the crop is sown thick and pulled up immediately after flowering; but it is generally left till the seed is ripe, and the fibre has become coarser. The finer kinds of hemp are used for making cloth, to which flax is more applicable, and the coarser for sail-cloth, canvas, ropes, &c. The dressing of hemp is very similar to that of flax. [FLAX.]

The seed of hemp is used for feeding birds, and for expressing an oil much used in Russia for burning in lamps, and in this country for making paint.

A beverage of intoxicating properties is extracted from hemp in India, and called Hashish. A medicine known as Indian hemp or bhang is another preparation from this plant, and is used in a similar manner to opium, without its unpleasant effects.

In the year 1864 the imports of all kinds of hemp into the United Kingdom amounted to 1,010,688 cwts., of the value of 1,745,353*l*. Of this quantity 540,093 cwts. came from Russia, 183,943 cwts. from the Philippine Islands, 157,299 cwts. from Austria, 75,522 cwts. from British India, and the remainder from other countries. In the same year 2,047,287 cwts. of jute and other vegetable substances of the nature of hemp, value 2,230,326*l*., were imported. The exports of hemp from the United Kingdom in 1864 amounted to 82,318 cwts., and of jute and other vegetable substances of a simi-

K

lar character, to 273,223 cwt., the largest quantities being sent to France, Belgium, United States, and British North America. [CANNABIS.]

HEMSTERHUYS, TIBERIUS, son of a French physician, was born at Groningen in 1685. In 1720 he succeeded Lambert Bos at Franeker as professor of Greek, and in 1740 removed to Leyden, where he was also professor of the same language. He contributed greatly to the revival of the study of the Greek language in Holland. He died 7th April, 1766. Among the works of Hemsterhuys are—the latter part of the edition of ‘Pollux’ by Lederlin, 1706; ‘Latin Orations,’ published by Valckenaer, 1784; and an edition of Lucian, 3 vols. 4to., which was completed by Reitz.

HE'NAULT, CHARLES JEAN, born at Paris in 1685, was the son of a fermier-général. He showed at an early age a taste for literature, and wrote several poems. Being made intendant-général of the queen's household, he became a great favourite. He was also appointed president of the Court of Enquêtes. In 1723 he was made a member of the French Academy. At the age of fifty he withdrew from the fashionable world, and gave himself up entirely to study and devotion; but his devotion was free from moroseness or superstition. He died at Paris in 1770. The work for which Henault is best known is his ‘Abrégé Chronologique de l'Histoire de France,’ which is a very good model of works of that kind. He wrote also ‘Histoire Critique de l'Etablissement des François dans les Gaules,’ and several dramatic works collected under the title of ‘Pièces de Théâtre,’ 1 vol. 8vo., 1770.

HENBANE. [HYOSCYAMUS.]

HENDERSON, THOMAS, was the son of a respectable tradesman at Dundee, where he was born, December 28, 1798. After an education such as his native town could afford, he was apprenticed to a writer (or attorney) for six years. At the end of this term he was sent to Edinburgh, at the age of twenty-one, to complete his legal instruction. He was then successively secretary to the celebrated Judge John Clerk of Eldin, the earl of Lauderdale, and the Lord-advocate Jeffrey; and in these employments he continued till 1831.

During his residence at Dundee he acquired a taste for practical astronomy, as well as for the history and literature of that science; and in 1824 he began to communicate with Dr. Thomas Young, then superintendent of the ‘Nautical Almanac,’ whom he assisted both by methods and calculations. On the death of Mr. Fallows, the Admiralty, in 1831, proposed to Mr. Henderson to succeed him in the charge of the observatory at the Cape of Good Hope, and the offer was accepted.

After vigorous application to his duties for little more than a year, he found his health and spirits give way, and he returned to Scotland in 1833, with a rich store of observations, the reduction of which he imposed upon himself as a voluntary duty; among these were the observations on α^1 and α^2 Centauri, which were made with a view of determining the effect of parallax in right ascension and declination. On the recommendation of the Astronomical Society of London, to whom Lord Melbourne applied for advice, Mr. Henderson was ap-

pointed the first astronomer royal for Scotland. Here he pursued his observations and researches till his death, which took place suddenly on the 23rd of November, 1844.

HENDRED, EAST. [BERKSHIRE.]

HENGIST and HORSÁ. These heroes are generally believed to have been the leaders of the first Anglo-Saxon invaders of ancient Britain in the fifth century; but modern historians throw discredit on this account, and believe that the invasion took place much earlier than the fifth century, and that the names Hengist and Horsa are only legendary. [SAXONS.]

HENLÉY-IN-ARDEN. [WARWICKSHIRE.]

HENLEY-ON-THAMES. [OXFORDSHIRE.]

HENNA. [LAWSONIA.]

HENNEBON. [MORBIHAN.]

HENRI I. of France, son of King Robert, succeeded his father in July 1031, being then about twenty-seven years of age. Henri's younger brother Robert, supported by his mother and the counts of Champagne and Flanders, contended with him for the throne; but peace was made by Henri giving to Robert the duchy of Burgundy. Henri married, in 1044, Anna, daughter of Jaroslav, duke of Russia, by whom he had several sons, the eldest of whom, Philip, was crowned at Rheims in 1059, at seven years of age, by order of his father, who died in the following year, leaving Philip I. under the guardianship of Baldwin, earl of Flanders.

HENRI II., born in 1518, succeeded his father Francis I. in 1547. In 1550 he concluded the war which was then pending with England, which gave up to him Boulogne for the sum of 400,000 crowns. In 1552 Henri assisted Maurice, elector of Saxony, and Albert, marquis of Brandenburg, who had united for the defence of the religious and civil liberties of Germany against Charles V.

After the abdication of Charles V. the war continued between Philip II. and Henri, whose troops, under the command of the Constable Montmorency, were defeated by the Spaniards at the battle of St. Quentin in 1557. The French arms were likewise unsuccessful on the side of Italy, where the duke of Alba commanded the Spaniards. The war ended in 1559, by the peace of Câteau-Cambresis, by which Calais, which had been taken the year before by the duke of Guise, remained in the hands of the French. At the same time a double marriage was concluded between Elizabeth, Henri's daughter, and Philip II. of Spain; and between Margaret, Henri's sister, and the duke of Savoy. The festivals given on this occasion had a tragical end. Henri was accidentally wounded at a tournament by the count of Montgomery, with the shaft of his broken spear, which struck the king on the right eye. Henri died shortly after, July 10, 1559.

HENRI III., born at Fontainebleau, in 1551, was the third son of Henri II. In 1573 he was elected king of Poland and the successor of Sigismund Augustus. Henri was crowned at Cracow; but a few months after, upon hearing of the death of his brother, Charles IX., he quitted Poland and returned to France, where he assumed the title of Henri III. His reign was a reign of unworthy favourites. When Paris revolted in favour of the Guises, Henri had recourse to assassination, and

caused the duke of Guise and his brother the cardinal to be murdered. Most of the towns in France rebelled; the Parliament of Paris instituted his trial; and the pope excommunicated him. In this emergency his generous enemy, Henri of Navarre, joined him with his army, repulsed the duke of Mayenne, the leader of the League, and the two kings laid siege to Paris. During this siege a fanatical Dominican monk, named Jacques Clément, excited by the declamations of the Ligueurs, assassinated Henri III. at St. Cloud, August 2, 1589. He left no issue, and in him terminated the dynasty of Valois, which had reigned in France since the accession of Philip VI. in 1328.

HENRI IV., king of France and of Navarre, was born at Pau in the Béarn, the 15th December, 1553. His father, Antoine de Bourbon, married Jeanne d'Albret, only daughter and heiress of Henri d'Albret, king of Navarre, after whose death, in 1555, Antoine became king of Navarre in right of his wife. In 1569 Henri was acknowledged at La Rochelle as the leader of the Calvinists. After the peace of 1570 he was invited to the French court, and two years after he married Margaret, sister of Charles IX. By the death of his mother in June, 1572, he became king of Navarre. At the massacre of the St. Barthélemy, which followed close upon his marriage, Henri's life was spared on condition of his becoming a Roman Catholic; but in 1576 he put himself again at the head of the Calvinists, and began a series of hazardous and hard-fought campaigns. Henri III., before he expired, named the king of Navarre as his successor. Henri, however, was opposed, and was obliged to raise the siege of the capital.

At last, in 1593, Henri began negotiations with several of the leaders of the League, and was induced to make a public profession of the Roman Catholic faith at St. Denis, on the 25th of July of that year. In March, 1594, Paris opened its gates to him, and Rouen and other cities followed the example. The peace of Vervins, concluded in 1598, put an end to the interference of Spain in the affairs of France.

The king applied himself to reform the administration of justice, to restore order in the finances, and to promote industry and commerce. He embellished Paris, and founded the hospital of La Charité Chrétienne for invalid officers and soldiers; he added to the collection in the royal library, and encouraged and rewarded men of learning.

By the Edict of Nantes, promulgated in 1598, Henri gave what he thought a full redress of the grievances under which his Protestant subjects laboured; and such it would have proved, had not the king's intentions been frustrated in great measure by the intolerance of parliaments and courts of justice. He was assassinated by Ravaillac, May 14, 1610, and was succeeded by his son Louis XIII., under the guardianship of Mary de Medici.

HENRICHEMENT. [CHIEF.]

HENRY I., king of England, surnamed Beauclerc, was the fourth and youngest son of William the Conqueror, and was born in 1068 at Selby in Yorkshire. The eldest son, Robert, was not favoured by his father, and succeeded him in the dukedom of Normandy, while the Conqueror, at his death in 1087, expressed his wish that his third son, William, should

be his successor in England, and only left Henry a legacy of 5000*l.* of silver. With 3000*l.* of this, however, Henry soon after obtained, from the facility of his brother Robert, the whole of the district of Cotentin, comprehending nearly a third of Normandy. When Robert and William, after having been at war in Normandy, made peace, they turned their united arms against Henry, who was compelled to evacuate even his last stronghold, the fortress built on the lofty rock of St. Michael, after which he wandered about for some two years in a state of nearly complete destitution. At length, on the invitation of the inhabitants of the town of Domfront, he assumed the government of that place; and it would appear that from this point of support he gradually raised himself to the repossession of nearly all the territory that he had lost. He also became reconciled to William, and was in England and in the New Forest with that king when he came by his death (2nd August, 1100). He was crowned on August 3, in Westminster Abbey. The next day he published a charter confirming the rights and liberties both of the church and of the nation, and promising the restoration of the laws of the Confessor, with only such alterations as had been made in them by his father. Henry from the first put forward his English birth as one of his chief claims to acceptance with his subjects; and he hastened to strengthen this title by his marriage with Maud, or Matilda, daughter of Malcolm, king of Scotland, and niece of Edgar Atheling.

The history of the reign opens with the contest between Henry and his elder brother Robert for the crown, which resulted in an agreement that Henry should retain England, and Robert Normandy, with the proviso that, if either died without legitimate issue, the survivor should be heir.

Henry, however, found excuses for breaking the agreement, and levied war upon his brother, the result of which was the utter ruin of Robert and his cause. He himself was taken prisoner, with 400 of his knights, and condemned by his brother to confinement for life. According to Matthew Paris, an unsuccessful attempt which he soon after made to effect his escape was diabolically punished by the extinction of his sight; and in this state the prince survived for twenty-eight years, dying in Cardiff Castle, at the age of eighty, in February, 1135, not quite twelve months before the death of Henry. Henry was, without opposition, acknowledged their duke by the Norman barons.

The next six or seven years passed without any events of much moment. In 1113, however, Henry was attacked in Normandy by Louis VI. of France, and Fulk, earl of Anjou, in support of the interests of William, styled Fitz-Robert, the son of Duke Robert. The war lasted about two years, and was on the whole adverse to Henry. It was followed by other contests which were not finally settled until 1120.

Immediately after the peace Henry's brightest hopes were dissipated by the frightful calamity of the loss, on the 25th of November, of the ship in which his son, who had been affianced to Matilda, daughter to the Earl of Anjou, had embarked at Harfleur for England: with the exception of one individual, a butcher of Rouen, all on board perished,

to the number of nearly 300 persons. Henry is said never to have been known to smile after this event. Two years before this he had lost his consort; and a daughter, Matilda, married in 1114 to the Emperor Henry V., was now his only legitimate progeny. In the hope of male offspring, he (February 2, 1121) espoused the young and beautiful Adelais, or Alice, daughter of Geoffrey, duke of Louvaine.

When four or five years of his second marriage had passed without producing any issue, Henry determined upon securing the succession to his dominions for his daughter, who had become a widow in 1125. On Christmas day, 1126, she was unanimously declared his heir, in a great council of the lords spiritual and temporal assembled at Windsor Castle. The following year she was married to Geoffrey, surnamed Plantagenet, the son of Fulk, earl of Anjou, to whom, although only a boy of sixteen, his father had resigned that earldom on his departure for the Holy Land, where he was a few years afterwards elected king of Jerusalem. It was not, however, till March, 1133, that Henry's longings were gratified by the birth of Matilda's first child, Henry, styled Fitz-Empress, afterwards Henry II. Henry I. died at Rouen on 1st December, 1135. He had completed the sixty-seventh year of his age and the thirty-fifth of his reign.

HENRY II., surnamed Fitz-Empress, was the eldest son of Geoffrey Plantagenet (so named from a sprig of broom—in Latin, *planta genista*—in French, *plante genêt*—which he used to wear in his cap), earl of Anjou, and Matilda. [HENRY I.] He was born at Le Mans, in March, 1133. In the struggle between Stephen and Matilda for the English crown [STEPHEN], Matilda's husband, Geoffrey, had, by the year 1141, reduced nearly the whole of Normandy, and his son Henry was, in 1150, formally invested with that dukedom by Louis VII. of France, the portion of the country called the Vexin being ceded to Louis as the price of his consent to such arrangement. By the death of his father, 10th September, 1151, Henry became earl of Anjou, Touraine, and Maine. On Whitsunday of the year following, within six weeks after she had been divorced from her first husband, King Louis of France, he married Eleanor, in her own right countess of Poitou and duchess of Guienne or Aquitaine, an alliance which made him master of all the western coast of France, with the exception only of Brittany, from the Somme to the Pyrenees. Soon after this, Henry sailed for England at the head of a small but well-appointed force. He and Stephen came in sight of each other at Wallingford, and in an interview which they had there, standing on opposite sides of the Thames, agreed to a truce. The death of Eustace, Stephen's eldest son, having removed the chief obstacle to a permanent arrangement between the two competitors, the death of Stephen, October 25, 1154, made Henry king of England without opposition.

His first proceedings were strikingly indicative of the system of combined energy and policy which continued to characterize his government. He dismissed the foreign troops which Stephen had brought into the kingdom, razed to the ground nearly all the numerous castles that had been erected throughout the country by the barons in the preceding twenty years of anarchy, and resumed with remorseless

determination all the lands that had been alienated from the crown since the death of Henry I., the grants only excepted that had been made to the church and to William, the second son of Stephen.

His presence was now called for across the seas by the attempt of his younger brother Geoffrey to wrest from him his paternal inheritance of Anjou, Touraine, and Maine. After a very short contest Geoffrey was forced to give up his claim in exchange for a pension, but he died about a year afterwards, in 1158. Partly by force, partly by management, Henry succeeded in acquiring possession of the whole of Brittany, the only portion of territory that was wanting to complete his sovereignty over all the western coast of France. Henry had already recovered from the young Malcolm IV. of Scotland the northern counties which had been taken possession of by his predecessor David I., and had driven back the Welsh from those parts of the English territory which they had seized during the reign of Stephen. His next attempt was upon the earldom of Toulouse, which he claimed in right of his wife Eleanor, whose grandfather William, duke of Aquitaine, had married Philippa, the only child of William, fourth earl of Toulouse. He was here opposed both by Raymond de St. Gilles, the descendant of a brother of Earl William, and by Louis, king of France. The contest which ensued was suspended by a peace in May, 1160, by which Henry was allowed to retain a few places he had conquered in Toulouse; and although the war soon broke out anew, it was after a few months put an end to by a second peace, concluded in 1162 by the mediation of Pope Alexander III.

The history of the reign of Henry II. for the next eight years is principally that of his contest with the archbishop of Canterbury. [BECKET.]

Meanwhile two formidable insurrections of the Welsh in 1163 and 1165 had been repressed. In 1166 a revolt of the people of Brittany against their duke, Conan, afforded Henry a pretext for assuming to himself the direct administration of affairs in the name of his son Geoffrey and Conan's daughter Constantia, between whom, young as they both still were, the marriage ceremony was now solemnized for the sake of this arrangement. On the 10th of September, 1167, Henry's mother, the ex-empress Matilda, died at Rouen. Some further hostilities in which he now became involved with the French king were, before producing any important result, terminated by a new peace concluded at Montmirail, 6th January, 1169. By this treaty it was arranged that Henry, the king of England's eldest son, should do homage to Louis for the earldoms of Anjou and Maine, and that his second son Richard should in like manner hold the duchy of Aquitaine of the French king, and espouse Adelais, or Alice, the youngest daughter of Louis. But the greatest event which divided the manifold activity of Henry with the affairs of Becket was the conquest of Ireland, which was begun in 1169 by a body of private adventurers, headed by Richard de Clare, earl of Pembroke, the celebrated Strongbow, and completed by Henry in person, who crossed over from Milford to Waterford with a powerful armament, 18th October, 1171, and a protracted struggle ensued between the people and their invaders; but the acquisition of Ireland was finally sealed by a formal treaty concluded in 1175 with

Roderick O'Connor, considered the head king of the country, in which he consented to become Henry's liegeman, and to pay an annual tribute.

Much of the remaining portion of Henry's life and reign presents an involved and deplorable scene of family discord and contention. His eldest son Henry had been, as heir-apparent, crowned in Westminster Abbey on Sunday, 15th of June, 1170. On this account, at the instigation, it is said, of King Louis, the prince advanced the pretension that he had become entitled actually to share the royal power with his father, and he demanded that Henry should resign to him either England or Normandy. His refusal was speedily followed (in March, 1173) by the flight first of the prince, and then of his younger brothers Richard and Geoffrey, to the French court. About the same time Queen Eleanor also left her husband to associate herself openly with the rebellion of her sons, of which she had in fact been the prime mover. She was also making her way for the French court when she was caught dressed in man's clothes and brought back to Henry, during the rest of whose life she remained in confinement. The cause of young Henry was supported not only by Louis, but also by William of Scotland, and by some of the most powerful both of the Norman and the English barons. The war continued for about two years, during which the most important event that happened was the capture of King William of Scotland at Alnwick Castle, 12th July, 1174. Soon after this, Henry, who had throughout decidedly the best of the contest, assented to the petition of his sons for a peace. In December, 1174, a treaty with Scotland had been signed, by which the Scots agreed to make acknowledgment of the feudal dependence of their crown on that of England, in return for the liberation of King William. In 1183 another outbreak of the fierce and turbulent spirit of the princes led the way to a new succession of family wars. After deserting his father and his youngest brother alternately about half a dozen times, Prince Henry was suddenly taken ill, and died at Château-Martel, 11th June, 1183, in the twenty-seventh year of his age; and Geoffrey was, in August, 1186, thrown from his horse at a tournament, and so severely injured that he died in a few days after. Richard, after unsuccessfully attempting to excite a new revolt in Aquitaine, was compelled to throw himself upon his father's clemency. A project of a new crusade at the call of Pope Clement III., in the beginning of 1188, for a moment united Henry and Philip, the new king of France. The impetuous Richard actually took the cross; but before the end of the same year the unhappy father saw his son again bearing arms against him in alliance with the French king. The pretext on the part of Philip and of Richard for this new war was Henry's refusal to deliver up the Princess Alice, the sister of the former, and the affianced bride of the latter, whose person as well as part of her dowry he had for many years had in his possession. Henry's spirit seems to have given way at last, and he sued for peace, which was granted on terms very humiliating to the king. Henry was stretched on a sick-bed when the treaty was read to him; but when he found in the list of those that had deserted him to join Richard, his youngest and favourite son John, the discovery appears to have broken his heart; he

turned himself to the wall, saying that all his interest in the world was over. He was soon after removed to Chinon, on the Loire; and there, after a few days more of suffering, he died, 6th July, 1189, in the fifty-seventh year of his age and thirty-fifth of his reign. He was buried in the choir of the abbey of Fontevraud.

The government of England during this reign was still nearly as despotic in principle as in the days of the Conqueror and his sons, but the more advanced social condition of the country and the firmer establishment of the new dynasty combined with the temper of the king to render it much less oppressive in practice.

HENRY III., surnamed of Winchester, was the eldest son of King John by his queen, Isabella of Angoulême, and was born 1st October, 1206. His father having died 18th October, 1216, the boy was, chiefly through the influence of the earl of Pembroke, acknowledged heir to the throne, and on the 28th was crowned in the abbey-church of St. Peter at Gloucester, by the papal legate, Gualo. His reign is reckoned from that day.

On the 11th November following, Pembroke was appointed protector or governor of the king and kingdom. After his death the administration fell into the hands of Hubert de Burgh. In 1222 Henry had been declared of age to exercise at least certain of the functions of government; but his feeble character was already become sufficiently apparent, and this formality gave him no real power. De Burgh conducted the government with ability and success, though in a spirit of severity which could not fail to make him many enemies. A growing opposition to De Burgh was at length headed by Richard, earl of Cornwall, the king's brother, and the consequence was the sudden expulsion of that minister from all his offices, and his consignment to prison, with the loss of all his honours and estates, in the latter part of the year 1232. Des Roches, the bishop of Winchester, who had retired from the country, returned, and was now placed at the head of affairs; but a confederacy of the laity and the clergy, with Edmund, archbishop of Canterbury, at its head, compelled his dismissal. The archbishop now became chief minister. In 1236 Henry, being now in his thirtieth year, married Eleanor, the daughter of Raymond, count of Provence. In the midst of contests between the crown and the nobility, whose meetings for deliberation on national affairs were now commonly called parliaments, a renewal of active hostilities with France was brought about through a private resentment of Henry's mother, Isabella, who, after the death of John, had returned, and had been remarried to Hugh, count of La Marche. Henry sailed for the continent; but, after being beaten by Louis in a succession of actions, he was glad to get home again, with the loss of army, money, baggage, and everything. A new truce for five years was then agreed to between the two countries.

The contest with the crown ended for the present in an attempt on the part of Henry to govern by the prerogative. The exorbitant extent to which Henry carried his exactions raised a spirit of resistance, which broke out into open revolt. What is called by most of the old chroniclers 'the mad Parliament' assembled at Oxford, June 11, 1258, and placed the

whole authority of the state in the hands of a committee of government, consisting of twelve persons appointed by the barons and as many by the king. The leader of the barons on this occasion was the famous Simon de Montfort, who was a Frenchman by birth, but who in right of his mother had succeeded to the English earldom of Leicester, and had married Eleanor, countess-dowager of Pembroke, a sister of King Henry. He and his friends soon contrived to monopolize the whole power of the committee. The quarrels of the adverse factions enabled Henry, in the beginning of 1261, to throw off their authority, and although the parliamentary party was on this occasion joined by Prince Edward, it was for the present effectually put down, De Montfort himself being obliged to take refuge in France. After a temporary restoration of De Montfort to power, we soon find the contending parties in open warfare, and on May 14, 1264, the forces of the barons, led by De Montfort, and those of the royalists, commanded by the king in person and by his son Edward, met at Lewes in Sussex, where the former gained a complete victory, both Henry and his son being taken prisoners. Prince Edward contrived to make his escape from Dover Castle, and to join the earl of Gloucester, who had now deserted the interest of De Montfort, at Ludlow, in Shropshire. On the 4th of August the two parties again encountered at Evesham; and the result was the defeat of the baronial forces with immense slaughter—De Montfort himself and his son Henry being both in the number of the slain. A final arrangement with the De Montfort party was at last effected in a parliament which met at Marlborough on the 18th of November, 1267. Henry's son Edward set out for the Holy Land in July, 1270, from which he had not returned when Henry died at Westminster, November 16, 1272, in the sixty-seventh year of his age and the fifty-seventh of his reign.

The reign of Henry III. is memorable as affording us the first distinct example of a parliament constituted, as at present, of representatives. Our statute law also begins with this reign.

HENRY IV., surnamed Bolingbroke, was the eldest son of John of Gaunt, duke of Lancaster, the fourth son of Edward III. His mother was the Lady Blanch, younger daughter and eventually heiress of Henry Plantagenet, duke of Lancaster, who was grandson of Edmund, second son of King Henry III. He was born at Bolingbroke in Lincolnshire in 1366. In 1397 he was created Duke of Hereford, having married Mary, daughter and coheir of Humphrey de Bohun, the last earl of Hereford.

The first occasion on which he appears in English history is as one of the lords associated with Thomas, duke of Gloucester, the uncle of Richard II., in the insurrection of 1387; and ten years after we find him accusing the duke of Norfolk, who was also concerned in the rebellion, of having spoken disrespectfully of the king, by expressing his opinion that, although Richard had received them into his favour, he still cherished a determination of revenge. It was determined that the charge should be brought before a high court of chivalry. That court assembled at Windsor on the 29th of April, 1398, and awarded that wager of battle should be joined between the two dukes at Coventry on the 16th of September. When

the day arrived, and the combatants were on the point of advancing to the encounter, the king, who presided, suddenly threw down his warder, and so arrested them both where they stood. Norfolk was ordered to go on a pilgrimage to the Holy Land, and was banished from England for life; Hereford was also sentenced to quit the kingdom within four months, and to remain abroad for the next ten years. He retired to Paris, and while he was resident in that city his father, the duke of Lancaster, died, February 3, 1399, on which Richard immediately seized his estates, on the pretence that the banishment of the son disqualified him from inheriting. Henry landed with a few attendants at Ravenspur in Yorkshire on the 4th of July, while Richard was in Ireland. Henry carried everything before him, and, the deposition of Richard having been pronounced by the Parliament, was on the 30th of September solemnly acknowledged as king by the estates of the realm assembled in Westminster Hall.

The new settlement was first disturbed by a plot to assassinate the new king, which, however, was detected in time. Military operations were then commenced on the side both of Wales and Scotland, in the former of which countries an insurrection, headed by the famous Owen Glendwr, baffled all Henry's efforts during several successive campaigns to put down; while two Scottish armies that marched across the borders pretending that they came to restore King Richard, who it was said was still alive and resident at the northern court, were defeated, the first on the 22nd of June, 1402, at Nesbet Moor, the second on the 14th of September in the same year, in the much more destructive fight of Homildon Hill. The victorious commander in this last affair was Harry Percy, the renowned Hotspur, eldest son of the earl of Northumberland. That great house, conscious of its power and its services, now broke with the king of its own making, on his refusal to permit the ransoming of Henry Percy's wife's brother, Sir Edmund Mortimer, who had been taken prisoner by Glendwr. A most formidable rebellion followed, but was annihilated on the 21st July, 1403, by the battle of Shrewsbury, in which Henry Percy was himself slain. Before the end of 1405 Owen Glendwr was effectually put down, and a truce with Scotland had restored quiet in that quarter. It was in the time of this truce that on the 30th of March, 1405, an English cruiser captured the ship in which James, the eldest son of King Robert of Scotland, was proceeding to France, on which Henry retained possession of the young prince, who, becoming king the following year by the death of his father, remained a prisoner in England till 1424. About the same time Henry detected a conspiracy against his life, one of the principal persons engaged in which was his cousin Edward, duke of York, whose estates were immediately forfeited to the crown; and he quelled another insurrectionary attempt of the Percys, headed by Scroop, archbishop of York, who expiated his treason by a death on the scaffold. A third northern insurrection, the last effort of the crafty old earl of Northumberland, who had some years before been deprived of his estates and outlawed, was put down, 28th of February, 1408, at the battle of Bramham Moor, near Tadcaster, in which the earl himself fell. Meanwhile an irregular war with France had

been carried on, but these transactions led to no important national results during this reign.

In his latter years Henry—whose character, the more it became known, developed a harsher and more unamiable aspect—lost all the popular favour that had greeted his accession. He breathed his last on the 20th of March, 1413, in the forty-seventh year of his age and the fourteenth of his reign.

Of the laws made in this reign the most memorable is the statute against the Lollards (2 Hen. IV. c. 15).

HENRY V., surnamed of Monmouth, from the place of his birth, was the eldest son of King Henry IV., by his first wife, and was born in 1388. He was educated at Queen's College, Oxford, under the superintendence of his half-uncle, the great Cardinal Henry Beaufort. When his father was in exile in 1399, he and a son of the late duke of Gloucester were carried to Ireland and placed in custody in the castle of Trim, where they remained till the deposition of Richard. On his father's accession he was created Prince of Wales, Duke of Guienne, Lancaster, and Cornwall, and Earl of Chester. It is said that the renown and popularity the prince acquired by his military successes in Wales so inflamed the jealousy of his father as to occasion his recall from the army, and that after this he drew upon himself as much reprobation by his wild and dissipated life as he had gained favour by his previous conduct.

Henry V. was proclaimed king on the 21st of April, 1413, the day after his father's death. He began his reign with several acts of a generous stamp—transferring the remains of Richard II. to Westminster Abbey; releasing the young earl of March from the captivity in which he had been held all the preceding reign; and recalling the son of Hotspur from his exile in Scotland to be reinstated in his hereditary lands and honours. He had been seated on the throne little more than a year when he entered upon the enterprise of the conquest of France, which forms nearly the whole history of his reign. The claim which he advanced to the French crown was the same that had been put forward in the preceding century by Edward III., to whose rights he seems to have regarded himself as the legitimate successor in virtue of his possession of the throne, although he was certainly not the heir of that king by lineal descent. Henry, having appointed his brother, the duke of Bedford, regent of the kingdom during his absence, set sail from Southampton, 13th August, 1415, with a force of 24,000 foot and about 6500 cavalry in a fleet of from 1200 to 1400 vessels, and on disembarking immediately proceeded to lay siege to the strong and well-garrisoned fortress of Harfleur. It capitulated after a siege of six weeks, in the course of which time, however, a dysentery that broke out in their camp made a frightful devastation among the English.

On the 6th of October Henry set out on his march through Normandy, with a force which at the utmost could not have exceeded 9000 men. On the 24th he came in sight of a French army, commanded by the constable of France and the dukes of Orleans and Bourbon, the strength of which has been variously estimated at from 50,000 to 150,000 men. The great battle of Agincourt was fought on the next day, in which the English gained one of the most complete as well as wonderful victories on record.

Henry returned to France in August, 1417, having under his command a magnificent army of about 35,000 men. The result of this expedition was the treaty of 'Perpetual Peace,' signed at Troyes, by which all Henry's demands were agreed to, namely—the hand of Charles' eldest daughter, the Princess Catherine; the present regency of the kingdom; and the succession to the throne of France on the death of Charles. Henry soon after set out with his queen for England, and on the 2nd February, 1421, entered London amidst such pageants and popular rejoicings as that capital had never before witnessed. In the course of the same year Henry led another army into France to resist the aggressions of the Dauphin, where his arms met with their customary success. But the end of Henry's triumphant career was now at hand. The Dauphin and the Constable Buchan having laid siege to the town of Cosne, Henry, though ill at the time, set out to relieve that place, but was unable to proceed farther than Corbeil, about twenty miles from Paris, when resigning the command to his brother the duke of Bedford, he was carried back in a litter to the Bois de Vincennes, in the vicinity of the capital, and there, after an illness of about a month, he breathed his last on the 31st of August, 1422, in the thirty-fourth year of his age and the tenth of his reign.

HENRY VI., surnamed of Windsor, was born 6th December, 1421, being the only issue of Henry V. by his queen, the Princess Catherine of France. He was not quite nine months old when the death of his father left him king of England. The actual administration of affairs in England was intrusted to the younger of his two uncles, Humphrey, duke of Gloucester, as substitute for the elder, John, duke of Bedford, who was appointed president of the council, but who remained in France, taking his late brother's place as regent of that kingdom.

The history of the earlier and longer portion of this reign is the history of the gradual decay and final subversion of the English dominion in France. The death of Henry V. was followed in a few weeks (22nd October) by that of his father-in-law, Charles VI. Immediately on this event the dauphin was acknowledged by his adherents as Charles VII.; and Henry VI. was also proclaimed in Paris, and wherever the English power prevailed, as king of France. The next events of importance that occurred were the two great victories of Crevant and Verneuil obtained by the English over the French and their Scottish allies, the former on the 31st of July, 1423, the latter on the 17th of August, 1424.

The extraordinary succession of events that followed—the appearance of Joan of Arc on the scene; her arrival in the besieged city of Orleans (29th April, 1429); the raising of the siege (8th May); the defeat of the English at the battle of Patay (18th June); the coronation of King Charles at Rheims (15th July); the attack on Paris (12th September); the capture of Joan at Compiègne (25th May, 1430); her trial and execution at Rouen (30th May, 1431)—all belong to the singular story of the heroic maid.

[ARC, JOAN OF.]

The young king of England, now in his ninth year, had in the meantime been brought to Rouen (May, 1430), and was about a year and a half afterwards crowned at Paris (December 17, 1431). In

1435 the duke of Burgundy concluded a peace with Charles, and a few days after the great duke of Bedford died. This event gave the finishing blow to the dominion of the English in France. In April, 1436, the English garrison in Paris was compelled to capitulate. In 1444 a truce was agreed upon, to last till 1st April, 1446; and in this interval a marriage was arranged between King Henry and Margaret, the beautiful daughter of René, king of Sicily and Jerusalem, and duke of Anjou, Maine, and Bar. In return for the hand of his daughter, he demanded the restoration of his hereditary estates of Maine and Anjou, which were in the possession of the English, and the proposal was at length assented to. The connection seemed to be one thoroughly French in spirit, and it is no wonder that the earl of Suffolk, by whom it had been negotiated, became from this time the object of much general odium and suspicion. The first remarkable event that followed was the destruction of the duke of Gloucester, who, although he appears not to have openly opposed the marriage, was certainly the most formidable obstacle in the way of the complete ascendancy of Suffolk and the queen. Having been arrested on a charge of high treason, 11th February, 1447, he was on the seventeenth day thereafter found dead in his bed. His death was generally attributed to the agency of Suffolk, who, now, raised to the dignity of duke, became, ostensibly as well as really, prime or rather sole minister.

Soon after hostilities were renewed in France, and a numerous force having been poured by King Charles into Normandy, town after town was speedily reduced; Rouen, the capital, surrendered, November 4, 1449; and the fall of Cherbourg, August 12, 1450, completed the loss of the duchy. Before this catastrophe the duke of Suffolk, after having been banished from the kingdom, was seized as he was sailing across from Dover to Calais, and being carried on board one of the king's ships, was there detained for a few days, and at last had his head struck off by an executioner who came alongside in a boat from the shore, May 2, 1450. The murder of Suffolk was immediately followed by a popular insurrection. [CADE, JOHN.] Before the close of the following year the French, in addition to Normandy, had recovered all Guienne; and, with the exception of Calais, not a foot of ground remained to England of all her recent continental possessions.

The remainder of the history of the reign is made up of the events that arose out of the contest for the crown which eventually placed another family on the throne. [EDWARD IV.] The king sunk into a state of mind amounting to absolute incapacity. By the beginning of the year 1455, however, he had recovered, and again took upon him the nominal administration of the government, which during his malady had been committed to the duke of York. In the contest that soon ensued, he was taken prisoner by the earl of Warwick at St. Alban's, 23rd May, 1455, and towards the end of that year he was again declared to be in a state of incapacity. Again, however, in a few months, Henry recovered his health, and the government was conducted in his name till his second capture by the young earl of March (afterwards Edward IV.) at Northampton, 10th July, 1460. On this occasion the queen escaped with her son, and eventually made her way to Scotland. The

victory obtained by Margaret over the earl of Warwick at Barnet Heath, 17th February, 1461, again liberated her husband; after which, and the issue of the battle of Towton, 29th March, which established Edward on the throne, he retired with the queen and Prince Edward to Scotland. When Margaret again invaded England in 1462, Henry was placed in the castle of Hardlough in Merionethshire; and here he remained till the spring of 1464, when he was brought from Wales to join a new insurrection of his adherents in the north of England. After the two final defeats of the Lancastrians at Hedgley Moor, 25th April, and at Hexham, 15th May, the deposed king lurked for more than a year in Lancashire and Westmoreland, till he was at last betrayed, and seized in Waddington Hall, in Yorkshire, in June, 1465. He was immediately conducted to London, and consigned to the Tower, where he remained in close confinement till the revolution of October, 1470, again restored him for a few months to both his liberty and his crown. He was carried from London to the battle of Barnet, fought 14th April, 1471, and there fell into the hands of Edward, who immediately remanded him to the Tower. The old man survived the final defeat of his adherents, and the murder of his son, at Tewkesbury, 4th May; and a few days after an attempt which had nearly succeeded was made by Thomas Nevil, called the Bastard of Falconberg, to break into his prison and carry him off by force. This probably determined Edward to take effectual means for the prevention of further disturbance. All that is further known is that on the 22nd of May, 1471, the dead body of Henry was exposed to public view in St. Paul's. It was generally believed, however, that he had been murdered by the king's brother, the duke of Gloucester, afterwards Richard III.

HENRY VII. was born at Pembroke Castle, 21st January, 1456. His father was Edmund Tudor (or rather Tydor, pronounced Tuddor, that is, Theodore), surnamed of Hadham, who had been created Earl of Richmond in 1452, being the son of Sir Owen Tudor and Queen Catherine, widow of Henry V. He was thus paternally descended both from the royal house of France, and also, it is said, from the ancient sovereigns of Wales. But it was his maternal extraction that gave Henry Tudor his political importance. His mother was Margaret, the only child of John Beaufort, duke of Somerset, whose father of the same name was the eldest of the sons of John of Gaunt, duke of Lancaster, the root of the Lancastrian house, by his third wife, Catherine Swynford.

Edmund Tudor died in 1456, the same year in which his son Henry was born. Throughout the stormy period that followed, the child found a protector in his uncle, Jasper Tudor, earl of Pembroke, till, on the accession of Edward IV. in 1461, the earl was attainted, and obliged to fly the country. Henry appears to have been then consigned by the new king to the charge of Sir William Herbert, Baron Herbert (afterwards created Earl of Pembroke), and to have been carried by that nobleman to his residence of Raglan Castle in Monmouthshire. He is said, however, to have been brought to court on the restoration of Henry VI. in 1470. After the battle of Tewkesbury he seems to have been sent back to Raglan Castle, and to have remained there till his

uncle, who had fled to France, returned secretly, and found means to carry him off to his own castle of Pembroke, and to embark with him at Tenby, with the intention of proceeding to France. They were forced, however, by stress of weather to put into a port of Bretagne, and there they were detained by the duke, Francis II., till after the accession of Richard III.

As soon as it came to be known that Edward V. and his brother no longer existed, Morton, bishop of Ely, suggested to the heads of his party that the crown should be offered to Henry on condition of his engaging to espouse the Princess Elizabeth, daughter of Edward IV., and since the death of her brothers the undoubted heiress of the rights of the house of York. The scheme received the assent of the leaders of the various interests confederated against Richard. A messenger was despatched to Henry in Bretagne, September 24, 1483, and he was informed that the general rising in his favour would take place on the 18th of October. Henry sailed from St. Malo with a fleet of forty sail; but a storm dispersed the ships as he crossed the Channel, and when he reached the English coast near Poole he deemed it prudent not to land. Meanwhile the hasty ill-combined revolt of Buckingham and his associates fell to pieces without the striking of a blow. Buckingham was taken and executed as a traitor. Henry himself returned to Bretagne. At length, on the 1st of August, 1485, Henry sailed with another fleet from Harfleur, and on the 7th landed at Milford Haven in Wales. The two rivals encountered at Bosworth in Leicestershire, on the 22nd, when Henry obtained a complete victory, which, with the death of Richard, who fell in the battle, at once placed the crown on his head. [RICHARD III.] Henry's marriage with Elizabeth was not solemnized till the 18th of January, 1486.

It was not to be expected that a reign commenced in such circumstances should be undisturbed by insurrectionary attempts. The first that occurred was headed by Francis, Viscount Lovel, in April, 1486, which was speedily and effectually put down. Before the end of the same year, however, a new and more formidable commotion was excited by the imposture of the boy Lambert Simnel, the son of a joiner at Oxford, who was put forward as Edward Plantagenet, earl of Warwick, the son and heir of the late duke of Clarence, brother of Richard III. The brief royalty of Simnel, however, was terminated, June 16, 1487, by the defeat of his adherents in the battle of Stoke. This imposture was followed after some years by the appearance of the more celebrated pretender Perkin Warbeck, who was asserted by his adherents to be Richard, duke of York, the younger brother of Edward V., and generally supposed to have been murdered along with him in the Tower. Warbeck arrived in Ireland from Lisbon in the beginning of May, 1492, and was afterwards acknowledged as duke of York, or rather as Richard, king of England, not only by the duchess of Burgundy, but by the governments both of France and Scotland. This affair occupied Henry for the next five or six years; for it was not till the end of 1497 that the adventurer was finally put down. Another pretended earl of Warwick next arose, one Ralph Wulford, or Wilford, the son of a shoemaker, whose attempt, however, was immediately nipped in the bud by his apprehen-

sion and execution, in March, 1499. The same year in which Wulford was put to death witnessed the executions of both Perkin Warbeck and the earl of Warwick. From this time Henry's reign was one of complete internal tranquillity, of which he chiefly took advantage to augment his revenue and his hoarded treasures.

Henry was early in his reign involved in the politics of the Continent by the quarrel which arose between Francis, duke of Bretagne, and Charles VIII. of France, each of whom applied to him for his assistance. This quarrel, by the death of Francis, became a contest for the possession of Bretagne by France. Charles eventually compelled the duchess of Bretagne to marry him, after she had been affianced to Maximilian, the king of the Romans; and the duchy was thus finally annexed to the French crown. The indignation of England at this result forced Henry to conduct an army to France in person, in the beginning of October, 1492; but he had already secretly arranged a peace with Charles, and before there was any fighting the treaty was published in the beginning of November. By this treaty, called the treaty of Estaples, Charles bound himself to pay Henry the sum of 149,000*l.* sterling, in half-yearly instalments of 25,000 francs.

By successive truces with James III. and James IV., the peace with Scotland was preserved till 1495. After Warbeck's final discomfiture, however, in 1497, a new truce was concluded between the two countries; and this led in 1502 to a treaty of perpetual peace, cemented by the marriage of James with Henry's eldest daughter, the Princess Margaret.

Nearly two years before this, namely, November 14, 1501, a marriage had been solemnized between Henry's eldest son Arthur, prince of Wales, and Catherine, the fourth daughter of Ferdinand, king of Castile. Arthur, however, who was a prince of the highest promise, died within six months after this time; and then it was arranged that Catherine should be married to his surviving brother Henry. The marriage of Catherine and Arthur proved still more momentous in its consequences than that of Margaret and James.

The Queen Elizabeth died February 11, 1503, a few days after giving birth to a daughter; the death of Henry took place at Richmond, April 22, 1509, in the twenty-fourth year of his reign and the fifty-third of his age.

HENRY VIII., the second son of Henry VII., was born at Greenwich, 28th June, 1491. On the 1st of November following he was created Duke of York, and in 1494 his father conferred upon him the honorary title of lord-lieutenant of Ireland. Sir Edward Poynings being appointed his deputy. It is stated that Henry was at first destined to the archbishopric of Canterbury; 'that prudent king his father,' observes Lord Herbert (in the History of his Life and Reign), 'choosing this as the most cheap and glorious way for disposing of a younger son.' He received accordingly a learned education.

Very soon after Arthur's death the singular project was started of marrying Henry to his brother's widow. The proposition appears to have originally come from Ferdinand and Isabella, who were anxious to retain the connection with England; and to have been assented to by King Henry in great part from

his wish to avoid the repayment of the dower of the princess. The final agreement between the two kings was signed 23rd June, 1503.

Henry became king 22nd April, 1509, being then in his nineteenth year. One of the earliest proceedings of the new reign was the trial and punishment of his father's ministers, Dudley and Empson. They were indicted for a conspiracy to take possession of London with an armed force during the last illness of the late king, and were beheaded together, on Tower Hill, 17th August, 1510.

Henry had not been long upon the throne when he was induced to join what was called the Holy League, formed against France by the pope, the emperor, and the king of Spain. In 1513 Henry passed over to France with an army, and, having been joined by the Emperor Maximilian, defeated the French, 4th August, at Guinegaste, in what was called the battle of the Spurs, from the unusual energy the beaten party are said to have shown in riding off the ground, and took the two towns of Terouenne and Tournay. On the 9th of September also, the Scottish king, James IV., who as the ally of France had invaded England, was defeated by the earl of Surrey in the great battle of Flodden Field, he himself with many of his principal nobility being left dead on the field. This war with France, however, was ended the following year by a treaty, the principal condition of which was that Louis XII., who had just lost his queen, should wed Henry's sister, the Princess Mary. The marriage between Louis, who was in his fifty-third, and the English princess, as yet only in her sixteenth year, was solemnized 9th October, 1514; but Louis died within three months, and scarcely was she again her own mistress when his young widow gave her hand to Charles Brandon, duke of Suffolk, an alliance out of which afterwards sprang a claim to the crown. [GREY, LADY JANE.]

A rivalry broke out between Richard Fox, bishop of Winchester, secretary and lord privy seal, and Thomas Howard, earl of Surrey (afterwards duke of Norfolk), who held the office of lord treasurer. This led to the introduction at court of Thomas Wolsey, who, being then dean of Lincoln, was brought forward by Fox to counteract the growing ascendancy of Surrey, and who speedily made good for himself a place in the royal favour that reduced all the rest of the king's ministers to insignificance, and left in his hands for a long course of years nearly the whole power of the state. [WOLSEY, CARDINAL.] For a short time Henry remained at peace, both with the Emperor Charles V., who had succeeded to the Spanish throne, and Francis; the former of whom paid him a visit at Dover in the end of May, 1520; and with the latter of whom he had a few days after a seemingly most amicable interview, celebrated under the name of the 'Field of the Cloth of Gold.' But before the close of the following year Henry joined in the league with the emperor and the pope; and in March, 1522, declared war against France. In the summer of the same year the emperor flattered him by paying him a visit at London; his vanity having also been a short time before gratified by the title of 'Defender of the Faith' bestowed upon him by Pope Leo X. for a Latin treatise which he had published 'On the Seven Sacraments,' in

confutation of Luther. Henry continued to attach himself to the interest of the emperor, until the disappointment, for the second time, of Wolsey's hope of being made pope through the influence of Charles, is supposed to have determined that minister upon a change of politics. Before the memorable defeat and capture of Francis at the battle of Pavia, 24th February, 1525, the English king had made every preparation to break with the emperor. In August he concluded a treaty of peace and alliance with France, and after the release of Francis in March, 1526, Henry was declared protector of the league styled 'Most Clement and Most Holy,' which was formed under the auspices of the pope for the renewal of the war against Charles.

Before this date two domestic occurrences took place that especially deserve to be noted. The first of these was the execution, in 1513, immediately before Henry proceeded on his expedition to France, of Edmund de la Pole, duke of Suffolk, whose mother was Elizabeth Plantagenet, sister of Edward IV. He was now put to death without any form of trial or other legal proceeding; his crime, there can be no doubt, being merely his connection with the House of York. In 1521 Edward Stafford, duke of Buckingham, son of the duke beheaded by Richard III., was apprehended on some information which was furnished to Wolsey by a discarded servant, and being brought to trial, was found guilty, and executed as a traitor. The acts with which he was charged did not according to law amount to treason, even if they had been proved; but the duke is said by certain indiscretions of speech and demeanour to have wounded the pride of the all-powerful minister. In 1527 Henry cast his eyes upon Anne Boleyn, and appears to have very soon formed the design of ridding himself of Catherine. [BOLEYN, ANNE.] Anne was understood to be favourably disposed towards the new views on the subject of religion. Henry himself, though he had been till now resolutely opposed to the new opinions, was carried over by his passion towards the same side. The proceedings for the divorce were commenced by an application to the court of Rome, in August, 1527. For two years the affair lingered on through a succession of legal proceedings, but without any decisive result. From the autumn of 1529 are to be dated both the fall of Wolsey and the rise of Cranmer. [CRANMER, THOMAS.] The death of the great cardinal took place 29th November, 1530. In January following the first blow was struck at the church by an indictment being brought into the King's Bench against all the clergymen of the kingdom for supporting Wolsey in the exercise of his legatine powers without the royal license, and it was in an act passed immediately after by the Convocation of the province of Canterbury, for granting to the king a sum of money to exempt them from the penalties of their conviction on this indictment, that the first movement was made towards a revolt against the see of Rome, by the titles given to Henry of 'the one protector of the English church, its only and supreme lord, and, as far as might be by the law of Christ, its supreme head.' Shortly after, the convocation declared the king's marriage with Catherine to be contrary to the law of God. In August, 1532, Cranmer was appointed to the archbishopric of Canterbury. In the

beginning of the year 1533 Henry was privately married to Anne Boleyn; and on the 23rd of May following Archbishop Cranmer pronounced the former marriage with Catherine void. In the meantime the Parliament had passed an act forbidding all appeals to the see of Rome. Pope Clement VII. met this by annulling the sentence of Cranmer in the matter of the marriage; on which the separation from Rome became complete. Acts were passed by the Parliament the next year declaring that the clergy should in future be assembled in convocation only by the king's writ, that no constitutions enacted by them should be of force without the king's assent, and that no first-fruits, or Peter's Pence, or money for dispensations, should be any longer paid to the pope. [ANNATES.] In the next session, the Parliament, which reassembled in the end of the same year passed acts declaring the king's highness to be supreme head of the Church of England, and to have authority to redress all errors, heresies, and abuses in the church. After this, various persons were executed for refusing to acknowledge the king's supremacy; among others, two illustrious victims, the learned Fisher, bishop of Rochester, and the admirable Sir Thomas More. [FISHER, JOHN; MORE, THOMAS.] In 1535 began the dissolution of the monasteries, under the zealous superintendence of Cromwell (afterwards earl of Essex), who was constituted for that purpose visitor-general of these establishments.

Events now set in a new current. The month of May of this year witnessed the trial and execution of Queen Anne—in less than six months after the death of her predecessor, Catherine of Arragon—and the marriage of the brutal king, the very next morning, to Jane Seymour, the new beauty, his passion for whom must be regarded as the true motive that had impelled him to the deed of blood. Queen Jane dying on the 14th of October, 1537, a few days after giving birth to a son, was succeeded by Anne, sister of the duke of Cleves, whom Henry married in January, 1540, and put away in six months afterwards.

In 1536 Cromwell was constituted a sort of lieutenant over the church, by the title of vicar-general, which was held to invest him with all the king's authority over the spirituality. The dissolution of the monasteries in this and the following year, as carried forward under the direction of this energetic minister, produced a succession of popular insurrections in different parts of the kingdom, which were not put down without great destruction of life, both in the field and afterwards by the executioner. In 1538 all incumbents were ordered to set up in their churches copies of the newly-published English translation of the Bible, and to teach the people the Creed, the Lord's Prayer, and the Ten Commandments, in English; the famous image of Our Lady at Walsingham, and other similar objects of the popular veneration, were also under Cromwell's order removed from their shrines and burnt. In 1539 the Parliament, after enacting (by the 31 Henry VIII., c. 8.) that the proclamation of the king in council should henceforth have the same authority as a statute, passed the famous act (the 31 Henry VIII., c. 14) known by the name of the Six Articles, or the Bloody Statute. This statute, the cause of numer-

ous executions, proceeded from a new influence which had now gained an ascendancy over the fickle king, that of Gardiner, bishop of Winchester, the able leader of the party in church and state opposed to Cranmer and Cromwell. [GARDINER, STEPHEN.] This new favourite was not long in effecting the ruin of the rival that was most in his way; Cromwell, who had just been created Earl of Essex and made lord chamberlain of England, was in the beginning of June, 1540, committed to the Tower on a charge of treason, and beheaded in a few weeks afterwards.

On the 8th of August this year Henry married his fifth wife, the Lady Catherine Howard, whom he beheaded, 13th February, 1542. During this interval he also rid himself by the axe of the executioner of Margaret, countess dowager of Salisbury, the daughter of the late duke of Clarence, and the last of the York Plantagenets. Her real crime was that she was the mother of Cardinal Pole, who had offended the tyrant, and who was himself beyond his reach.

In the latter part of the year 1542 war was declared by Henry against Scotland. The failure of his efforts to obtain possession of the government and of the young queen, Mary Stuart, led to a renewal of hostilities in the spring of 1544, when Scotland was invaded by a great army under the earl of Hertford, which penetrated as far as Edinburgh, and burned that capital, with many other towns and villages. In the preceding year, also, Henry had concluded a new alliance with the emperor against the French king; and in July, 1544, he passed over with an army to France, with which he succeeded in taking the town of Boulogne. On this, however, the emperor made a separate peace with Francis; and on the 7th of June, 1546, Henry also signed a treaty with that king, in which he agreed to restore Boulogne and its dependencies in consideration of a payment of two millions of crowns.

He had some years before found a sixth wife, Catherine Parr, the widow of the Lord Latimer, whom he married 10th July, 1543. As the infirmities of age and disease grew upon him, the suspiciousness and impetuosity of his temper acquired additional violence. One of his last butcheries was that of Henry Howard, earl of Surrey, who, being convicted of treason, was executed in January, 1547. Surrey's father, the duke of Norfolk, was also to have suffered on the 28th, but was saved by the death of the king at two o'clock on the morning of that day.

The most important changes made in the law during this reign were those affecting ecclesiastical affairs, of which the principal have been already noticed. Along with these may be mentioned the statute defining the degrees within which marriage should be lawful (25 Henry VIII., c. 22). The law of real property was also materially affected by the Statute of Uses (27 Henry VIII., c. 10), and by the statutes which permitted the devise, which was not before allowed, except by the custom of particular places, of real estates by will. To this reign is also to be assigned the origin of the Bankrupt Laws. Wales was first incorporated with England, and the laws and liberties of England granted to the inhabitants of Wales, in the twenty-seventh year of Henry VIII.; and Ireland, which before was styled only a lordship, was in 1542 erected into a kingdom.

HENRY OF HUNTINGDON, an ancient English historian, the son of Nicholas, a married priest, was born about the end of the 11th century, and was educated under Alcuin of Anjou, a canon of Lincoln Cathedral. He was made archdeacon of Huntingdon some time before 1123. He composed a general history of England, from the earliest accounts to the death of Stephen, 1154, in eight books, published by Sir Henry Saville among the 'Scriptores post Bedam,' folio, London, 1596. The exact time of his death is not known.

HENRY, MATTHEW, an eminent nonconformist divine, was born at a farmhouse in Flintshire, October 18, 1662. His father left the Church of England in consequence of his refusal to subscribe to the Act of Uniformity. Matthew Henry received the principal part of his education under Mr. Doolittle of London. In 1685 he commenced the study of the law in Gray's Inn; but he soon relinquished this profession, and, after being ordained in 1687, settled at Chester as minister of a dissenting congregation. In 1712 he left Chester, and became the minister of another congregation at Hackney. He died on the 22nd of June, 1714.

The work by which Matthew Henry is principally known is his 'Exposition of the Old and New Testament,' which originally appeared in 5 vols. folio, but which he did not live to complete. He was also the author of many other works; of which the principal are, 'Inquiry into the Nature of Schism;' 'Life of Philip Henry;' 'Scripture Catechism;' 'Communicant's Companion;' 'Discourses against Vice and Profaneness;' 'Method of Prayer;' and numerous sermons on separate subjects.

HENRY, ROBERT, D.D., was the son of a farmer in the parish of St. Ninians, Stirlingshire, where he was born in 1718. Having completed his education at the University of Edinburgh, he was licensed as a preacher in 1746, being then master of the burgh or grammar-school of Annan, in Dumfriesshire. In 1748 he was elected minister of a Presbyterian congregation at Carlisle, with which he remained till August, 1760, when he removed to a similar situation in the town of Berwick-upon-Tweed. In 1768 Mr. Henry removed to Edinburgh. His first appointment was as minister of the church of the New Grey Friars, which he retained till 1776, and then exchanged for the easier charge of one of the ministers of the Old Church, in which he continued till his death. His access to the libraries at Edinburgh encouraged him to proceed with a design which he had long entertained, of a 'History of England on a New Plan.' The first volume, in 4to., appeared in 1771, the second in 1774, the third in 1777, the fourth in 1781, and the fifth, bringing down the narrative to the accession of Henry VII., in 1785. The author, upon whom the degree of D.D. had been conferred by the University of Edinburgh in 1770, died in 1790; but before his death he had completed the greater part of another volume of the history, extending to the accession of Edward VI., which was published in 1793.

HENRY, WILLIAM, was the son of Mr. Thomas Henry, of Manchester, a zealous cultivator of chemical science. Dr. Henry was born on the 12th of December, 1775. His earliest instructor was the Rev. Ralph Harrison. After studying at Edinburgh

and elsewhere, he received the diploma of Doctor in Medicine in 1807. He subsequently and successfully practised as a physician in Manchester, but he was compelled to retire from it on account of the state of his health.

Though pursuing the engrossing occupations of his profession, he both zealously and successfully attended to the science of chemistry, and contributed a great number of important papers to the Royal Society, the Philosophical Society of Manchester, and to various philosophical journals. He died on the 2nd of September, 1836, in his sixty-first year.

HENRYSON, ROBERT, a Scottish poet of much merit, lived in the latter part of the fifteenth century. Of his life hardly anything is known. His tale of 'Orpheus Kyng,' was printed at Edinburgh in 1508; and in 1593 there was printed his 'Testament of Faire Creseide,' 'Robin and Makyne' is known to most readers from Percy's 'Reliques.' Other specimens of Henryson's poems are in Sibbald's 'Chronicle of Scottish Poetry,' in Dr. Irving's 'Lives of the Scottish Poets,' and in Ellis' 'Specimens.' The fullest collections of them, however, are in Lord Hailes' 'Ancient Scottish Poems,' 1770, and in a volume containing his thirteen poems, called 'Fables,' edited by Dr. Irving in 1832, for the Bannatyne Club.

HENSLOVIA/CEÆ, a very small natural order of Exogens, according to Lindley nearly related to *Hydrangeaceæ*. *Henslovnia* consists of three or four species inhabiting the tropical parts of India.

HEONG-SHAN, a district town in the province of Quan-tung, China, on a branch of the Canton river, 22 miles N.W. of Macao, and first visited by the British war steamer *Nemesis*, on an exploring voyage in 1841. The district of the same name extends 30 miles from north to south, and 25 from east to west, intersected by several deep watercourses.

HEPATIC (Gr. *hepar*, 'the liver'), a term of very general use in anatomy and medicine, as applied to the liver, and its various functions and affections; as the *hepatic duct*, and the *hepatic artery*, situated between the lobes of the liver; *hepatic vein*, the hepatic vessels; *hepatic glands*, which receive the vein within the liver; *hepatic plexus*, a kind of convoluta connected with the vena portæ and the Hepatic vessels; *hepatic glands*, which receive the absorbents of the liver. The *hepatic flux* is an overabundant discharge of bilious secretion. The term is also frequently applied to mineralogical objects, from their resemblance to the dark blood-red colour of the liver; as *hepatic pyrites*, or *hepatic sulphuret of iron*, a variety of prismatic iron pyrites, which, on exposure to the weather, receives a brown tarnish, and through oxidation becomes finally decomposed. *Hepatic cinnabar* is a dark-coloured variety of cinnabar, and the *Mercure Sulphur of Hany*.

HEPATICE, a name formerly applied to a class of cryptogamic plants, part of which are popularly called Liverworts. It is now subdivided into several natural orders. [JUNGERMANNIACEÆ; MARCHANTIACEÆ.]

HEPATITIS. [LIVER, DISEASES OF.]

HEPATUS, Latreille's name for a genus of brachyurous crustaceans (Crabs), placed by Milne-Edwards under the tribe of *Calappians*, and, as that writer thinks, forming a link between the *Calappians*

(which they resemble in the disposition of their chelæ), and the *Cancerians* (which they approach in general form), as well as the *Leucosians* (from which they differ little as regards the details of the mouth).

The only species known, viz., *Hepatus fuscatus*, and *Hepatus Chiliensis*, are inhabitants of the coasts of America; the first having been found in the north, and at the Antilles, the second on the coast of Valparaiso. (M. Edwards.)

HEPHESTION. [ALEXANDER III., the Great.]

HEPHESTION, a grammarian of Alexandria, lived about the middle of the second century of the Christian era. He wrote a treatise on Greek metres (*Εὑχρησίδιον περὶ Μέτρων*), the best edition of which is by Gaisford, 8vo., Oxford, 1810.

HEPIALIDÆ, a family of lepidopterous insects of the section *Lepidoptera nocturna* of Latreille. The moths belonging to this family are distinguished by the want of tongue, the wings being deflexed, long and narrow, and the thorax devoid of crest. Their larvæ live in the interior of vegetables, on which they feed, or in some instances they live in the ground, and feed upon the roots of plants; they are fleshy, naked, and have six thoracic, eight abdominal, and two anal feet. The pupæ have the segments of the body denticulated. The principal genera contained in this family are *Hepialus*, *Cossus*, *Stygia*, and *Zeuzera*.

HEPTACHORD (Gr. *hepta* and *chordai*, 'seven chords'), a system of seven musical sounds, which, among the classical ancients, implied two conjunct tetrachords. The interval of the heptachord was equivalent to our seventh. In ancient poetry the word signified certain verses that were sung to the music of seven chords; that is, seven different tones or notes. In this sense the term was generally applied to the lyre, when it had but seven strings.

HEPTAGON, a figure of seven sides.

HEPTARCHY. [ENGLAND.]

HERACLE'UM, a genus of plants belonging to the natural order *Umbelliferae* and the tribe *Peucedaneæ*. *H. sphondylium*, Cow Parsnip, is a native of Europe, and probably of Siberia, and is found plentifully in the meadows and hedges of Great Britain. It affords wholesome and nourishing food for cattle, and is collected in Sussex for fattening hogs; hence it is sometimes called Hog-weed. The seeds of the plant are diuretic and stomachic, and exhale a powerful odour. *H. pubescens* is a native of Taurida in the shady places, and of the Caucasus, in alpine places. The young shoots are filled with a sweet aromatic juice, which is eaten by the natives of the Caucasus in a crude state. *H. Pyrenaicum* is a native of the Eastern and Central Pyrenees, and of Italy.

HERACLI'DÆ, the descendants of Hercules. According to tradition, after the death of Hercules, his children took refuge in Attica, in order to escape the persecution of Eurystheus, and they were hospitably received by Theseus. With the assistance of the Athenians, they defeated Eurystheus, and after the battle they are said to have obtained possession of the whole of Peloponnesus; but they had not remained in the country long before a pestilence again drove them back to Attica. They attempted soon afterwards to march again

into Peloponnesus, but were met at the Isthmus by an army consisting of Arcadians, Ionians, and Achæans. In a single battle with Echemus, king of Tegea, Hyllus, the eldest son of Hercules, was slain, and the Heraclidæ promised not to invade Peloponnesus for a hundred years. They did not, however, observe their engagement, for both Cleodæus, son of Hyllus, and his grandson Aristomachus, renewed the attempt, but without success. The Heraclidæ retreated to Doris, where they obtained a considerable army to assist them in the recovery of their dominions. With the aid of an Ætolian chief named Oxyllus, they crossed from Naupactus to the southern side of the Corinthian Gulf eighty years after the Trojan War. (Thucyd. i., 12.) A battle took place between the Dorians under the command of the sons of Aristomachus and the Peloponnesians under that of Tisamenus, the grandson of Agamemnon, in which the latter were defeated, and all Peloponnesus, except Arcadia and Achæa, fell into the hands of the Heraclidæ. Elis was assigned to Oxyllus, and the rest of the Peloponnesus was divided among the three sons of Aristomachus; Temenus obtained possession of Argos, Cresphontes of Messenia, and Aristodemus, or his sons Eurysthenes and Procles (for according to the general tradition Aristodemus did not live to enter Peloponnesus) of Lacedæmon. The land of the conquered country was divided among the Dorians, and the old inhabitants were obliged to emigrate, or were reduced to an inferior caste.

Such is the traditional account of that important event in Grecian history, usually called 'the return of the Heraclidæ,' by which the Dorians obtained possession of the greater part of the Peloponnesus. Though the general tradition assigned the complete conquest of Peloponnesus to the sons of Aristomachus, it appears probable from other traditions that the greater part of the Peloponnesus was not reduced by the Dorians till long afterwards. (Thirlwall's 'Hist. of Greece,' vol. i., pp. 262-273.)

HERACLITUS of Ephesus, surnamed the Naturalist, belongs to the dynamical school of the Ionian philosophy. He is said to have been born about B.C. 500, and he died in the sixtieth year of his age. The title he assumed of 'self-taught' refutes the claims of the various masters whom he is said to have had, and the distinguished position that he held in political life attests the wealth and lustre of his descent. The gloomy haughtiness and melancholy of his temperament led him to despise all human pursuits, and he expressed unqualified contempt as well for the political sagacity of his fellow-citizens as for the speculations of all other philosophers, as having mere learning and not wisdom for their object. Of his work 'On Nature' (*περὶ φύσεως*), the difficulty of which obtained for him the surname of 'the Obscure,' many fragments are extant, and exhibit a broken and concise style, hinting rather than explaining his opinions.

According to Heraclitus, the end of wisdom is to discover the ground and principle of all things. He maintains that the rational principle which governs the whole moral and physical world is also the law of the individual; whatever therefore is, is the wisest and the best; and 'it is not for man's welfare that his wishes should be fulfilled; sickness

makes health pleasant, as hunger does food, and labour rest.'

The physical doctrines of Heraclitus formed no inconsiderable portion of the eclectic system of the later Stoics, and in times still more recent there is much in the theories of Schelling and Hegel that presents a striking though general resemblance thereto.

The fragments of Heraclitus have been collected from Plutarch, Stobæus, Clemens of Alexandria, and Sextus Empiricus, and explained by Schleiermacher in Wolf and Buttmann's 'Museum der Altherthumswissenschaft,' vol. i. See also Brandis' 'Handbuch der Geschichte der Griechisch-Röm. Philos.,' Berlin, and Ritter's 'History of Ancient Philosophy,' Oxford.

HERACLIUS, the son of the patrician Heraclius who was governor of Africa under the Emperor Phocas, assisted in dethroning the latter in 610, and was proclaimed emperor in his place. He applied himself to reform the discipline of the army; he renewed the truce with the Longobards of Italy, and turned his arms against the Avari, who had invaded Thrace, and had advanced to the gates of Constantinople. Those barbarians soon after retired across the Danube loaded with their spoils. The Persians meantime invaded Syria, devastated Jerusalem, and made an irruption into Egypt, in consequence of which the large supplies of corn which that country used to send to Constantinople were stopped, and the capital was afflicted by a severe famine. Another Persian army had advanced through Asia Minor to Chalcedon, but Heraclius induced the commander to withdraw, and sent ambassadors to treat of peace with Khosru, the Persian king, who spurned his offers, and summoned Heraclius and his subjects to abjure Christ and pay worship to the sun. Heraclius, roused by this insult, collected an army, and marched against the Persians, whom he defeated in a succession of brilliant campaigns, and pursued them as far as the Tigris, in 622-27. The first year of the expedition of Heraclius against the Persians was the same in which Mohammed openly assumed the character of prophet and legislator, after his flight to Medina. Khosru was at last dethroned by his son Siroes, who concluded peace with Heraclius. The latter years of the reign of this emperor were passed amidst theological controversies. Heraclius supported the doctrine of the Monothelites, who taught that the human nature in Jesus Christ was entirely passive under the will of his divine nature. Pope John IV. assembled a council at Rome in 640, which condemned the Monothelites. Meantime the Arabians, after the death of Mohammed, and under the caliphate of Abu Bekr, invaded Syria, Palestine, and Mesopotamia, and under the following caliphate of Omar they conquered Egypt and Cyrenæa. Heraclius was unable to oppose the torrent of Arabian courage and fanaticism; he sunk into inactivity and sloth, and died of dropsy in February 641, after a reign of thirty years. From that epoch the decided though gradual decline of the Eastern empire may be dated. Heraclius was succeeded by Heraclius Constantine, his son by his first wife Eudocia, who in the fourth month of his reign was poisoned by his step-mother Martina, who had her own son Heraclionas proclaimed in his stead. An

insurrection, however, soon after broke out at Constantinople against the new emperor, who was mutilated and banished together with his mother; and Constans II., son of Heraclius Constantine, was raised to the imperial throne. (Theophanes and other Byzantine historians; Gibbon.)

HERALD, an officer whose duty, during the middle ages, was to carry challenges or peaceful messages from one prince or nobleman to another, to proclaim peace or war, to lay out the lists in jousts or tournaments, to be the witness of all combats, and to record in writing the names of those who behaved most valiantly, to number the dead after battle, and specially to supervise all matters connected with the bearing of coat-armour, the marshalling of processions, and other state ceremonies. His functions were something like those of the Greek *kerux* (κέρυξ), and the Roman *Fecialis*; but the origin of the name is much disputed, and the actual date of the institution uncertain. The earliest mention of a herald in England is in the reign of Edward III.; but there is little doubt that the office existed as early at least as the dawn of hereditary coat-armour. There are three orders or grades of heralds, namely, kings of or at arms, heralds, and pursuivants. They were anciently created with much ceremony, but are now appointed by the earl marshal in England, and by the Lyon king-of-arms in Scotland.

The present number in England is thirteen. Three kings-of-arms—Garter, Clarencieux, and Norroy; six heralds—Somerset, Chester, Windsor, Richmond, Lancaster, and York; and four pursuivants—Rouge Dragon, Portcullis, Blue Mantle, and Rouge Croix. In Scotland there is one king-at-arms, named Lyon; six heralds—Snowdown, Albany, Ross, Rothesay, Marchmont, and Hay; and five pursuivants—Uncorn, Carrick, Kintyre, Ormond, and Bute. Ireland has one king-at-arms, Ulster; two heralds, Cork and Dublin; and two pursuivants, Athlone and St. Patrick. To these regular officers are sometimes added, by command of the king to the earl marshal, a herald or pursuivant extraordinary.

HERALD'S COLLEGE, or COLLEGE OF ARMS, a corporation founded by Richard III., in the first year of his reign, by a charter dated the 2nd of March, 1483, in which he gives to the principal officers of the corporation a house called Colde Arbor, in the parish of All Hallows the Less, London. In the first year of the reign of Henry VII. this house was seized into the king's hands under the Act of Resumption as the personal property of John Writhe, then garter king-at-arms. During the reign of that king and of his successor Henry VIII. the heralds made several unsuccessful attempts by petition to obtain a restoration of it, or the grant of some other building for their general use. King Edward VI., in the third year of his reign, by a charter dated June 4th, confirmed to them all their ancient privileges; and Philip and Mary, by charter of the 18th of July, 1554, re-incorporated them, and granted to them Derby House, then occupying the site of the present college on St. Benet's Hill, near St. Paul's Churchyard. The old building was destroyed in the great fire of London, but all the books, papers, &c., were saved, and removed to the palace in Westminster, where the heralds held their chapters, &c.,

until the college was rebuilt. The corporation consists of the heraldic officers of England under the presidency of the earl marshal, an office now hereditary in the family of Howard, duke of Norfolk. [HERALD.] There is a heralds' college in Scotland, termed the Lyon Court.

HERALDRY, the art of arranging and explaining in proper terms all that appertains to the bearing of coats of arms, badges, and other hereditary or assumed marks of honour; also the art of marshalling processions and conducting the ceremonies of coronations, instalments, creations of peers, funerals, marriages, and all other public solemnities.

The origin of heraldry, in the first and most commonly understood sense, has been attributed, by the general consent of the best writers on the subject, to the necessity for distinguishing by some outward sign, amidst the confusion of battle, the principal leaders during the expedition for the recovery of the Holy Land. But nothing is absolutely known concerning it beyond the fact that the middle of the twelfth century is the earliest period to which the bearing of heraldic devices properly so called can be traced; and the commencement of the thirteenth, the time about which they became hereditary.

The earliest roll of arms of which we have any notice is of the reign of Henry III.; and the reign of Edward I. presents us with the earliest heraldic document extant. The famous roll of Caerlaverock, a poem in old Norman French, rehearses the names and armorial ensigns of all the barons, knights, &c., who attended Edward I. at the siege of Caerlaverock Castle in 1300. Heraldry is therein first presented to us as a system. The principal rules and terms of the art were then in existence, and from about that time the terms are continually found in the fabliaux and romances of France and England.

The oldest writer on heraldry whose work has descended to us is Nicholas Upton, whose treatise 'De Militari Officio' was composed in the reign of Henry V., and translated in that of his successor by Juliana Berners, in the work known as the 'Boke of St. Albans.' As Upton quotes no earlier authorities, his definitions and explanations can only be looked upon as assertions made nearly 300 years after the origin of the practice, and consequently to be believed, or not, according to the discretion of the reader. In the reign of Richard III. the English heralds were incorporated and the college of arms founded, and in the following century a swarm of writers arose, both in France and England, each contradicting the other, and wasting much learning and research in the most absurd and idle controversies.

On the decline of chivalry the study of heraldry became gradually neglected, and the art which had formed for centuries a portion of the education of princes, and occupied the attention of some of the most learned men in Europe, was abandoned to the coach-painter and the undertaker, while kings-of-arms and pursuivants were looked upon as mere appendages of state pageantry, their office ridiculed, and their authority defied.

That the pedantry of such writers as Morgan, Ferne, Mackenzie, and others, contributed to these results, there can be little doubt. A taste for the critical study of antiquities generally is now, however, reviving throughout Europe, and the use of

heraldry as a key to history and biography is daily becoming more acknowledged.

The rules of heraldry as now practised at the college of arms are, as we have before remarked, comparatively modern, and vary in some points from those observed in France and Germany.

According to the received authorities there are ten classes of arms.

1. Arms of *Dominion*, being those which princes bear as annexed to the territories they govern.

2. Of *Pretension*, those borne by princes who are not in possession of the dominions to which such arms belong, but who claim or pretend to have a right to such possession; as, for instance, the kings of England from Edward III. to George III. quartered the arms of France.

3. Arms of *Community*, being those of bishops, cities, universities, and other bodies corporate.

4. Of *Assumption*, such as are assumed by a man of his proper right without the grant of his prince, or of a king-at-arms: as, for instance, when a man of any degree whatsoever has taken prisoner, in lawful war, any gentleman, nobleman, or prince, he may bear the arms of that prisoner, and transmit them to his heirs for ever.

5. Arms of *Patronage*, such as governors of provinces, lords of manors, patrons of benefices, &c., add to their family arms, as a token of their superiority, rights, and jurisdiction.

6. Arms of *Succession*, borne by those who inherit certain estates, manors, &c., either by will, entail, or donation.

7. Arms of *Alliance*, such as the issue of heiresses take up to show their maternal descent.

8. Arms of *Adoption*, borne by a stranger in blood, with the special permission of the prince, applied for in order to fulfil the will of the testator who may bequeath certain moneys or estates on condition of the party's assuming his name and arms.

9. Arms of *Concession*, augmentations granted by the prince of part of his own ensigns or regalia to such persons as he pleases to honour therewith.

10. Arms *Paternal* and *Hereditary*, such as are transmitted from the first possessor to his son, grandson, great-grandson, &c.; thereby forming complete and perfect nobility. The son being a gentleman of second coat-armour, the grandson a gentleman of blood, and the great-grandson a gentleman of ancestry.

These several sorts of arms are displayed on shields or escutcheons, and on banners, the ground of either being called the field, and the figures borne upon it the ordinaries and charges.

The reader will find this subject very fully illustrated in the plates HERALDRY, 1-7.

HERAT. [AFGHANISTAN; PERSIA.]

HE'RAULT, a maritime department in the south of France, formed out of a portion of Bas-Languedoc, is bounded N. by the departments of Aveyron and Gard, E. by that of Gard, S. by the Gulf of Lyon and the department of Aude, and W. by the departments of Aude and Tarn. Its greatest length from E. to W. is 84 miles, from N. to S. 49 miles. The area is 2393 square miles, and the population at the last census was 409,391.

The department is traversed in the north and north-west by the lower CE'VENNES, which attain

the height of 4198 feet in the Espinouse range on the confines of Tarn, and of 4264 feet in the chain of Larzac, or Larjac, extending N. of Lodève into the department of AVEYRON. From the main chain several ranges of hills of moderate elevation branch off towards the south, gradually subsiding as they approach the sea. The cultivable soil of the north and north-west consists of a chulky clay which produces only rye. The higher mountains are in general barren, or covered with woods. The plains in the interior, some of which are of large extent, consist of a light gravelly soil, very favourable to the growth of the vine and the olive. Along the lower courses of the Orb, the Hérault, and the Vidourle, and generally in the south of the department, the soil is strong, deep, rich, and very productive in all the cereal grains. Here and there, all through the department, there are extensive wastes, locally called *garrigues*, thinly covered with shrubs, dwarf oak, heath, broom, cistus, and aromatic plants, and producing tolerable pasture. The department presents abundant evidence of volcanic action at some distant period, particularly in the extinct craters of Agde and of St. Thibéry, near Pézenas, and in the basaltic hills near Montpellier.

The coast line, extending from the mouth of the Aude to that of the Vidourle, measures 66 miles in length. The salt lagunes of Thau, Maguelonne (so called from the ancient city of Maguelonne, which stood on the peninsula of Maguelonne, and of which there remains a very interesting church), Pérols, and Mauguio extend eastward from Agde to the Vidourle; they are separated from the Mediterranean by a narrow bank, in which, however, there are a few openings, called *graus*. The Canal des Etangs, which joins the Canal du Midi at Cette, passes through these lagunes. In the west of the department are the lagunes of Vendres and Capestang: the latter is land-locked and stagnant. The neighbourhood of all these lagunes is marshy and unhealthy; agues and rheumatic fevers prevail in the summer and autumn, though to a less extent than formerly, owing to the partial drainage and cultivation of the marshes. Except in the vicinity of the lagunes, the department enjoys a pure air and a most healthy climate.

The rivers of the department all rise in the Cévennes, and flow directly into the Mediterranean or into the lagunes. The principal are: the *Vidourle*, on the confines of GARD; the *Lez*, which passes E. of Montpellier, and becoming navigable takes the name of Canal de Grave: the *Hérault*, which gives name to the department; rising in the north-west of Gard, and running south, it enters the department of Hérault at Ganges; here, having received the Ergue on the right bank, it passes Montagnac and Pézenas, and enters the sea through the port of Agde after a course of eighty miles, only seven of which are navigable: the *Orb*, which, springing from the mountains W. of Lodève, and flowing first S., then W. till it meets the Jaur at Olargues, and finally S.S.E., passes Béziers, having previously received the Bernasobre from the west, and enters the sea near St. Geniès; and the *AUDE*, which touches the western boundary. Near the coast, most of the towns are joined to the Canals du Midi and des Etangs by short canals, thus establishing a

communication with Beaucaire and the towns on the Rhone [GARD] and the Garonne, and with the Gulf of Gascogne.

The department is crossed by the high road from Paris to Spain, through Perpignan, by five other royal and seventeen departmental roads. Montpellier, the capital, communicates with Cette and Nîmes by railroad. [GARD; CETTE.]

About a fourth of the entire area consists of arable land, and about a sixth is under vineyards. Wheat, rye, barley, and oats are produced in quantity more than sufficient for the consumption. There is a considerable breadth of artificial meadows; and large crops of lucerne, sainfoin, and clover are grown. For the quantity of wine produced, Hérault stands at the head of the wine-growing departments of France, the average annual produce being nearly 50,000,000 gallons. The red wines of St. Georges, St. Christol, and St. Drézéry, the muscatel wines of Frontignan, Lunel, and Béziers, and the white wines of Marseillan and Pinet, are considered the best. Fruits, especially raisins, olives, almonds, figs, and chestnuts, and all kinds of pulse, are grown. The mulberry is cultivated for the production of silk; aromatic and medicinal herbs, and plants used for dye-stuffs, are gathered. The principal material of the woods are the chestnut and green and white oak. Sheep, cattle, and mules are numerous; game is very abundant; and fish, including the john dory, tunny, oyster, lobster, anchovy, mackerel, eel, &c., are taken in immense quantities in the lagunes and in the sea.

The industrial products comprise woollen cloths for the army, and for exportation to Spain and Italy, silks, hosiery, calico, muslin, flannel, blankets, brandy, chemical products, pottery, tiles, honey, perfumes, leather, oil, beer, paper, &c. There are also numerous dye-houses, and establishments for the rearing of silkworms. Shipbuilding is carried on at Cette and other towns on the coast. Mines of coal, iron, lead, and copper, quarries of marble, building and mill stone, slate, gypsum, and granite are worked. A great quantity of salt is made by evaporation on the lagunes and on the shore of the Mediterranean, this department being one of the chief sources for the supply of that article to France. There are several mineral springs. The exports consist of most of the articles enumerated, but chiefly of wine, dry fruits, and brandy. The imports are wool, cotton bales, staves, colonial produce, raw hides, cork, &c. The principal sea-ports are CETTE and Agde. About 100 fairs are held annually.

The department is divided into four arrondissements, which, with their subdivisions and population, are as follows:—

Arronds.	Cantons.	Communes.	Pop. in 1863.
Montpellier, .	14	114	162,151
Béziers, . .	12	99	142,287
Lodève, . .	5	73	57,691
St. Pons, . .	5	45	47,262
Total, . .	36	331	409,391

Of the arrondissement of Montpellier, and of the whole department, MONTPELLIER is the capital.

Aniane, a pretty little town, 16 miles N.W. from Montpellier, is situated in a rich plain on the left bank of the Hérault, and has 3557 inhabitants who manufacture cream of tartar, verdigris, black soap, chemical products, cotton yarn, leather, and lime. This town owes its origin to the abbey built here by St. Benedict in the ninth century; the abbey (now the parish) church is an elegant structure; the abbey buildings are turned into a cotton factory. *Cette*. *Frontignan*, a small town with 2574 inhabitants, situated on the lagune of Maguelonne, and on the Montpellier and Cette Railroad, is famous for the excellent muscatel wines and raisins produced in its neighbourhood. Near Frontignan is *Balaruc*, famous for its warm springs, which have enjoyed a long celebrity for the cure of paralytic and scrofulous affections. The bathing establishments, furnished hotels for the accommodation of visitors, and a general hospital for poor patients, forming a pretty village, stand on the northern shore of the lagune of Thau. There are two seasons, May and June, September and October. The resident population is given at 690. *Ganges*, 25 miles N. from Montpellier, is prettily situated in a fertile plain closed in by high hills, and on the left bank of the Hérault. It is surrounded by pretty country houses, and commanded by an old castle. The population amounts to 4470, and the chief manufactures are silk and cotton yarn, silk stockings, silk gloves, and leather, with a trade in wine. Near the town there is a very extensive grotto, which is said to surpass in beauty the famous grotto of Antiparos. A great deal of raw silk is produced in the canton of Ganges. *Lunel-la-ville*, 14 miles E. from Montpellier, and on the railroad from that city to Nîmes, stands near the right bank of the Vidourle, in a district famous for its sweet wines, and has 6737 inhabitants. The most attractive objects in the town are the barracks, a fountain in form of an obelisk, and the public promenade. It has communication by the Lunel Canal, which terminates in the lagune of Mauguio, with the Rhone, the Mediterranean, and the Canal du Midi. There are several brandy, spirit, and liqueur distilleries; and the trade in corn, flour, wool, wine, raisins, manufactured goods, and colonial produce is considerable. *Massillargues*, or *Marsillargues*, 15 miles E.N.E. from Montpellier, on the Vidourle, is situated in a very fertile district; it has a fine old castle, and 3446 inhabitants. *St. Martin de Londres*, 17 miles N.N.W. from Montpellier, is a small place of only 1047 inhabitants, but interesting for the remains of its feudal fortifications, and for the old castle of La Roquette, which stands on an eminence near the Pic St. Loup, a volcanic mountain nearly 2000 feet high. Silk hosiery and charcoal are manufactured here. *Mauguio*, 6 miles from Montpellier, stands on the lagune of Mauguio, has some brandy distilleries, and 2550 inhabitants. In the middle of the town there is a hill, surmounted by a windmill, from which Aigues-Mortes and Cette, on the coast of the Mediterranean, and to the northward the Cévennes, are visible. There is a station of the Nîmes railway at Mauguio. *Mèze*, 19 miles S. from Montpellier, stands in a productive vine district on the lagune of Thau, where it has a good harbour for small craft under 60 tons burden. It is a pretty town with 6106 inhabitants, who manufac-

ture liqueurs, brandy, and salt, and trade in these articles, and in wine, corn, &c. The ancient abbey of Vallemagne, the church and cloisters of which are still entire, stands near Mèze, and forms one of the finest Gothic structures of the kind in France.

In the arrondissement of Béziers, the chief town, *Béziers*, stands on a hill above the Orb and the Canal du Midi, in $43^{\circ} 20' \text{ N. lat.}, 3^{\circ} 12' \text{ E. long.}$, 38 miles S.W. from Montpellier, and has 24,270 inhabitants. The streets are narrow and ill-laid out, but the houses are in general well built of stone. It contains several buildings interesting for their architecture or their antiquity; the principal are the cathedral of St. Nazaire; the churches of St. Aphrodise and La Madeleine; the former episcopal palace which now serves for the residence of the sub-prefect, and for courts of justice; the public library; the house of Pierre Paul Riquet, the engineer of the Canal du Midi; the market-house; and the barracks. The town has a tribunal of commerce and a college. The manufactures consist of woollen cloth, silk, hosiery, dimity gloves, parchment, verdigris, confectionery, brandy, spirits, liqueurs, chemical products, thrown silk, soap, leather, paper, glass, &c.; the commerce of the town consists of these articles and of corn, wool, iron, wine, oil, fruits, &c. A steam engine raises the waters of the Orb to a considerable height into a reservoir on the terrace, near the cathedral, whence the different quarters of the town are supplied. The Canal du Midi is carried through nine locks close to the town. The town of Béziers is ancient; it contains a few Roman remains, and is noted for the massacre of the Albigenes, July 22, 1209. *Agde*, a seaport and fortress at the embouchure of one of the branches of the Canal du Midi, and on the left bank of the Hérault, which is crossed by a suspension bridge, has a remarkably beautiful Gothic church, an exchange, a harbour for vessels of 200 tons, and 9747 inhabitants. The harbour is formed by the channel of the Hérault, which has a depth of sixteen feet, and is lined with quays formed of lava all the way to the sea. The fortifications, public buildings, and the houses are constructed of black basalt, and the streets are paved with volcanic products got from the Mont St. Loup. The town stands about two miles from the Mediterranean; it has an active coasting trade and fishery, a lighthouse of the first class, a school of navigation, and slips for building trading-vessels. Soap, verdigris, and brandy are the chief manufactures; the commerce is composed of these articles, and of wine, oil, fish, timber, iron, cordage, pitch and tar, corn and flour. About 120 vessels of 100 to 200 tons belong to the town. *Bédarieu*, a well built manufacturing town on the left bank of the Orb, which separates it from one of its suburbs, stands 18 miles N. from Béziers, and has 9087 inhabitants. Fine and coarse woollens, cotton and woollen hosiery, silks, hats, soap, olive oil, leather, and paper are manufactured. There are also dye-houses, glass works, and a copper foundry. The trade in wine and in the articles just named is extensive and important. *Capestang*, which gives name to the lagune of Capeatang, stands on the Canal du Midi, and has 2746 inhabitants. There are manufactures of cream of tartar and of brandy in the town. *Florensac*, situated near the left bank of the

Hérault, in a rich district of vine and meadow land, has a population of 3756. *St. Gervais*, a small town of 2256 inhabitants, is situated in a well-watered valley shut in between four hills, 22 miles N. from Béziers. There are excellent coal mines near the town, and also marble quarries and limekilns. *Montagnac*, the birthplace of Latude, celebrated for his long captivity in the Bastille, stands on the left bank of the Hérault, and has brandy distilleries, some unimportant manufactures, and 3719 inhabitants. *Murviel*, on a hill above the Orb, eight miles from Béziers, has a population of 1712. *Pézenas*, an ancient town, situated near the left bank of the Hérault, at its junction with the Peine, has an exchange, a college, and 7204 inhabitants. The town is well built, with pretty wide streets and good houses; the parish church and the theatre are the most remarkable buildings. The neighbourhood is remarkably beautiful, and so well cultivated as to have gained the title of the Garden of Hérault. *Pézenas* is celebrated for its salubrity; several craters, now extinct, and masses of basalt, are seen near it. It was in this town that Molière wrote his '*Précieuses Ridicules*.' The manufactures are linen, muslin, calico, woollen stuffs, hats, soap, chemical products, syrup and sugar of grapes, cotton yarn, and raw silk. There are also brandy and spirit distilleries, establishments for washing wool, and a considerable commerce in corn, olive oil, fruits, &c. *Roujan*, a small place in a volcanic district, near the right bank of the Peine, has a population of 1900; near it there are extensive coal mines, and also cold mineral springs. *Servian*, 8 miles N.E. from Béziers, has 2285 inhabitants. There is a castle here, the construction of which dates from the eleventh century.

In the arrondissement of Lodève, the chief town, *Lodève*, situated in a valley at the foot of the Cévennes, on the left bank of the Ergue, which here receives the Salondres, is 32 miles N.W. from Montpellier, and contains 11,864 inhabitants. It is the seat of tribunals of first instance and of commerce, and has also a chamber of commerce, a college, and a council of prud'hommes. The town is surrounded by strong walls, but the interior is badly built and ill laid out. The approaches to it are by avenues of fine trees. The air is pure, and the environs delightful; the hills around it are cultivated to their very summits, and plantations of the vine, the olive, and the mulberry everywhere meet the view. The most remarkable building in Lodève is the former cathedral church of St. Etienne, which contains a beautiful mausoleum in white marble of one of the bishops of Lodève. The town is the centre of a great cloth manufacture, and is celebrated for its piece-dyed goods, which are exported to the Levant. Soldiers' uniforms and other woollen stuffs, soap, leather, &c., are also made. Lodève is noted as being the birthplace of the celebrated Cardinal Fleury. *Clermont-Lodève*, 10 miles S. from Lodève, stands on the slope of a hill above the little river Ydromiel, and contains 6405 inhabitants. A college, a tribunal of commerce, a council of prud'hommes, and a savings' bank, are the principal institutions of the town. The most remarkable building is a handsome Gothic church with three naves, a very lofty tower, and, over the principal entrance, a rose

window of noble dimensions. Besides a good trade in rural products, the principal manufacture is piece-dyed cloth; but woollen and cotton hosiery, handkerchiefs, cotton yarn, leather, brandy, and chemical products are also manufactured. *Gignac*, near the left bank of the Hérault, is situated 12 miles S.E. from Lodève, in a country covered with vineyards, olive grounds, and mulberry plantations, and has 2778 inhabitants, who manufacture verdigris, olive oil, sugar, brandy, and woollen yarn, and trade in agricultural produce. *Lumas*, 7 miles from Lodève, has a population of 1407. Its neighbourhood produces famous cheese.

In the arrondissement of St. Pons, the chief town, *St. Pons*, stands on the Jaur, a feeder of the Orb, 56 miles W. from Montpellier, and has 6497 inhabitants. It is a well built town; most of the houses are constructed of marble from the neighbouring quarries. The church of St. Pons, which is classed as an historical monument, is one of the most interesting in the department. Within the town the Jaur receives the waters of a very abundant spring, which forms a vast basin of considerable depth; in front of this there are two immense elms, on the right a church built in the time of Charlemagne and well preserved, and on the left a Gothic tower. The town has a tribunal of first instance, a college, and an ecclesiastical school: the waters of the Jaur drive the machinery of several corn and fulling mills, saw-works, dye-houses, &c. There are important manufactures of woollen cloth in this town; hosiery, woollen yarn, and leather are also made; and there is a good trade in corn, cattle, and marble. *St. Chinian*, important for the manufacture of piece-dyed woollen goods, brandy, and leather, stands in a rich valley watered by the Bernasobre, 12 miles S.E. from St. Pons, and has 4339 inhabitants. *Olargues*, 11 miles N.E. from St. Pons, on the Jaur, a feeder of the Orb, has a population of 1017. *Olonzac*, 16 miles from St. Pons, near the Canal du Midi, has 1763 inhabitants. *La Salvetat*, 8 miles N.N.W. from St. Pons, is situated among high mountains, near the right bank of the Agout, a feeder of the Tarn, and has a population of 3777, who manufacture flannel, woollen cloth, woollen yarn, and swanskin, and trade in wool, cattle, and the excellent butter of the neighbourhood, which is considered the best in all Languedoc.

The department forms the see of the bishop of Montpellier, is included in the jurisdiction of the Cour Royale and University Academy of Montpellier, and belongs to the 10th Military Division, of which Montpellier is head-quarters. It returns three deputies to the Corps Legislatif.

(*Dictionnaire de la France; Annuaire pour l'An 1866; Statistique de la France.*)

HERBACEOUS PLANTS, or HERBS, are those plants the stalks of which are soft, and have nothing woody in them. Some of them have a root of hard wood. *Sweet herbs* are those used for flavouring, as mint; *pot-herbs* are valued for their nutritive qualities.

HERBARIUM, a collection of dried plants. When the plants have been brought home, all their parts should be spread out, freed from folding and overlapping, put between folds of cartridge paper, and gently pressed. Having remained under pressure for a night, they should be turned, put on fresh

paper, and thoroughly pressed. They are then to be fixed permanently to paper by a little gum, gently pressed after the gum is dried, named according to their natural orders, genera, and species, with the localities in which they had been gathered, and placed in the cabinet. Much care should be exercised in the process of pressing and drying. It is also important to secure the roots of manageable herbaceous plants, and to mark the season at which they were gathered.

HERBERT, JOHANN FRIEDRICH, was born in 1776 at Oldenburg, where his father at the time held an office connected with the administration of justice. Receiving his religious instruction from a man well acquainted with the philosophical systems of Leibnitz and Kant, Herbart, at the age of about twelve, was led to speculate upon such subjects as God, freedom, and immortality. In his eighteenth year he went to the University of Jena, where he studied under Fichte, and formed an intimate acquaintance with him, and he entertained the highest opinion of his master until Schelling's work, 'Vom Ich' (Of the I), fell into his hands, which was admired by Fichte, while Herbart opposed its tendency with the greatest zeal. This caused a breach between Fichte and Herbart, who gladly accepted the office of private tutor which was offered to him at Berne, in Switzerland. He had already conceived the idea of a system of psychology based upon mathematics, and the more clearly Fichte explained his views upon psychology in his 'Sittenlehre' (Doctrine of Morals), Leipzig and Jena, 1798, the more Herbart became convinced that the speculations of Fichte must be abandoned if any permanent basis was to be gained for his science. About the same time he devoted himself to the study of ancient philosophy, which led him to form an intimate acquaintance with the systems of Plato and the Eleatics. From 1802 to 1805 he delivered philosophical lectures in the University of Göttingen, where he developed his peculiar method of thinking. His tendency was pre-eminently practical, and it was partly owing to this circumstance, and partly to his personal acquaintance with Pestalozzi, that his first works treated on education. In 1809 he was appointed professor of philosophy at Königsberg, and was at the same time intrusted with the superintendence of the higher educational establishments in the eastern parts of Prussia, in the organization of which he did great service. In 1833 he was invited to the chair of philosophy in the University of Göttingen, where his lectures attracted great attention on account of the clearness and precision with which he explained his views. He remained at Göttingen until his death, which occurred on the 14th of August, 1841.

Herbart is the founder of a particular system of philosophy, which is interesting on account of his peculiar method rather than his originality of thought, for in reality his system is of a syncretic kind, and Fichte's influence upon it cannot be mistaken.

HERBELOT, BARTHELEMI D', was born at Paris, December 14, 1625. He commenced the study of the Oriental languages in early life, and acquired an accurate knowledge of the Arabic, Hebrew, Syriac, Persian, and Turkish languages. He was appointed Oriental secretary and interpreter to the king of

France, and subsequently professor of Syriac on the death of Auvergne. He also received a pension from the king. He died 8th of December, 1695.

The work by which D'Herbelot is known to posterity is entitled 'Bibliothèque Orientale, ou Dictionnaire Universel, contenant généralement tout ce qui regarde la Connoissance des Peuples de l'Orient,' folio, Paris, 1697. He also wrote several other works, which have never been published. Amongst these a Turkish and Persian Dictionary, in three volumes folio.

HERBERT OF CHERBURY, EDWARD, LORD, was born in the year 1581, at Montgomery, in Wales. After going through the usual course of studies at Oxford, Herbert visited London in 1600, and shortly afterwards proceeded to the Continent, where he joined the English auxiliaries in the Netherlands, and was soon distinguished by reckless daring and intrepidity. Having returned to England, he was, upon the accession of James I., created a knight of the Bath, and was distinguished at court by his gallantry and learning. In 1618 Sir Edward was sent ambassador to France: in this situation the bold independence with which he answered a remark of the Comte de Luynes brought upon him the displeasure of the French monarch, at whose request he was recalled. The conduct of Herbert met, however, with the approbation of James, who, upon the death of De Luynes, sent him again to Paris, where he published his first work, entitled 'Tractatus de Veritate, prout distinguitur à Revelatione, à Verisimili, à Possibili, et à Falso,' 4to., Paris, 1624. The year following he returned to England, and was created a baron of the kingdom of Ireland. In 1631 he was elevated to an English peerage, and two years after published an enlarged edition of the 'Tractatus,' of which another appeared in 1645, accompanied with the treatise 'De Religione Gentilium, Errorumque apud eos Causis.' Upon the outbreak of the political troubles under Charles I., Lord Herbert at first took the side of the Parliament, which, however, he subsequently abandoned at a great sacrifice of personal interests and fortune. He died in the year 1648. After his death two posthumous works were published, the 'Expeditio Buckinghami Ducis in Ream Insulam,' and the 'Life and Reign of King Henry VIII.,' with a dedication to the first Charles. It is by the latter work that Lord Herbert is best known to posterity. His Memoirs, which are the earliest instance of autobiography in our language, remained in manuscript until they were printed, in 1764, by Horace Walpole, at Strawberry Hill.

Herbert of Cherbury was the contemporary of Hobbes of Malnesbury, to whose principles of philosophising he was directly opposed, notwithstanding the striking coincidence of many of the results at which they respectively arrived.

HERBERT, GEORGE, born April 3, 1593, was the fifth brother of Lord Herbert of Cherbury. He was educated at Westminster, and elected thence to Trinity College, Cambridge, about the year 1608. In 1615 he became fellow of the college, and in 1619 was elected public orator. He was made prebendary of Leighton Bromswold, or Layton Ecclesia, in 1626. He married in 1630, and in the same year accepted the rectory of Bemerton. He died in 1632. His poetical works are well and

deservedly known. His chief prose work is 'The Priest to the Temple,' a sequel of his work called 'The Temple; Sacred Poems and Private Ejaculations.'

HERBERT, HON. ALGERNON, barrister-at-law, and sixth son of Henry, first earl of Carnarvon, was born in 1792, and educated at Eton. He passed through the university honours at Oxford with distinguished *éclat*; and was called to the bar in 1818. He was a man of extraordinary learning, and may be considered as the first and most original writer of the day in that peculiar line of antiquarian research in which he engaged. His first work was printed anonymously, under the title of 'Nimrod, or a Discourse upon certain Passages of History and Fable.' It was republished in two volumes in 1828; and succeeded by a third and fourth, which contained many erudite articles on a variety of subjects; such as Roma, Antichrist, Apocrypha, Cosmogonia, Paradise, the Deluge, Ammon, Alchymus, &c. Mr. Herbert afterwards published, in two thin quarto volumes (1836 and 1841), a work entitled 'Britannia after the Romans: being an attempt to illustrate the religious and political revolutions of that province in the fifth and succeeding centuries.' This was followed by an Essay on the 'Neo-Druidic Heresy,' 'Nennius, the Irish version of the *Historia Britonum*' (1848); and 'Cyclops Christianos, an Argument to disprove the supposed Antiquity of Stonehenge and other Megalithic Erections in England and Brittany' (1849). He died in 1855.

HERBERT, SIDNEY, *Lord Herbert of Lea*, statesman and minister, son of the eleventh earl of Pembroke, was born at Richmond in 1810. Educated at Harrow and at Oriel College, Oxford, he entered the House of Commons in 1832, in the conservative interest, as member for South Wilts, which he continued to represent until his elevation to the peerage. He was appointed secretary of the Admiralty in Sir Robert Peel's ministry of 1841. In 1845 he became secretary-at-war, and went out of office with his party after the repeal of the corn-laws. On the formation of Lord Aberdeen's coalition ministry he resumed his post of secretary-at-war. He was for a few weeks colonial secretary in the first administration of Lord Palmerston in 1855, and secretary-at-war in his second administration in 1859. His labours both in the House of Commons and in his office had so impaired his health that he was forced to resign his seat; and early in 1861 he was raised to the peerage. The state of his health compelled Lord Herbert to resign office, and proceed to Spa, whence he returned to England, and died at Wilton, near Salisbury, August 2, 1861. To him are due the re-organization of the army medical department and of the militia, the organization of the volunteer force, the efficient fortification of our dockyards, the extension of the Armstrong gun-factory, and great improvements in the sanitary condition and education of the army. He possessed winning and genial manners, and a singular aptitude for business, was a good debater, an eminent philanthropist, and a liberal patron of the arts. He married, in 1846, the daughter of Major-general Ashe & Court, of Armingtoun Hall, Warwickshire, niece of Lord Heytesbury; and his eldest son, born in 1850, is now earl of Pembroke, earl of Montgomery, and Baron Herbert of Shurland, Cardiff, and Lea.

HERCULANEUM, a very ancient Italian city, situated on the coast of Campania, near Naples. In the time of Titus, A.D. 79, it was overwhelmed by that memorable eruption of Vesuvius which also ruined Pompeii. It appears to have been buried under showers of ashes, subsequently overflowed by streams of lava; and is from 70 to 120 feet below the present surface of the ground. It was re-discovered by the sinking of a well in 1713, when several antiquities were found. This led to further investigation; and after several years, in which little was done, the Neapolitan government undertook the work of excavation. The theatre, a chalcidicum, and two temples were the chief buildings explored: the private houses are chiefly small, and of one story, like those of Pompeii. The whole excavation is said to have been about 600 yards long by 300; but it being impossible to remove the incumbent soil, in consequence of its thickness, as fast as one part was thoroughly searched, it was filled up with rubbish from another. The theatre is very large, having eighteen rows of stone seats, and could have accommodated 8000 persons. The chief advantage as yet derived from Herculaneum is the magnificent collection, not only of statues and paintings and vases, but of domestic implements of every use and description, deposited in the Royal Museum at Naples.

Great expectations were raised by the discovery of a large number of manuscripts written on rolls of papyrus. The attempts to decipher them hitherto have had but imperfect success; and those of which the subjects have been ascertained are of little interest. These manuscripts contain the works of Greek philosophers and sophists, and treat of natural and moral philosophy, medicine, criticism, the arts, &c. During the past few years systematic excavations have been made on the portion of Herculaneum which was situated nearest the sea, and which had only been covered by loose ashes. By this means the ancient buildings are seen to great advantage, and new and important discoveries are often made.

HERCULES, the offspring of Zeus by Alcmena, daughter of Electryon, a son of Perseus, and king of Mycenæ. His reputed father was Amphitryon (son of Alceus, another of the children of Persens), who, having accidentally killed his father-in-law Electryon, was compelled to leave Mycenæ and take refuge in Thebes. Here Hercules was born and educated, and here his early feats of strength and valour were done; such as slaying the lion of Cithæron, delivering Thebes from the tribute to Erginus, king of Orchómenos, and taking in marriage the daughter of Creon.

Being fated to serve Eurystheus, king of Mycenæ, he performed what are called his twelve labours, in obedience to the commands of his master. The legends of Hercules perhaps afford a better instance than those of any other hero or god, except Apollo, of the various sources from which mythical accounts spring. Hercules is represented as a half-naked man, with broad shoulders and brawny limbs, resting on a club, and covered round his loins with the skin of the Nemean lion.

HERCULES, one of the old constellations, called *ἑρкулίων* by Aratus, Hyginus, and Ptolemy, and described by the first as, 'a figure like that of a man in sorrow,' while the second offers various fabular significations from the stories of Hercules, Orpheus,

Theseus, Thamyris, Ixion, Prometheus, &c. The club, lion's skin, and character of Hercules are not so old as Aratus, who describes this figure as stretching his hands to different quarters, and makes an allusion to the neighbouring dragon, which shows that he was not painting a hero.

The constellation is situated between Draco, Boötes, Lyra, and Ophiuchus; but as there is no star in it larger than of the third magnitude, there is nothing very remarkable about it. The principal stars α and δ lie between the bright stars in the head of Ophiuchus and in Corona Borealis.

HERCULES-BEETLE (*Dynastes Hercules*), a species of coleopterous insect of the section *Pentamera* and family *Dynastidae*, or Prince-beetles. This species is a native of Brazil, and is from four to six inches long. The head is marked by a horn, or process, of great length in proportion to the body. This proceeds from the upper thorax, and is lined below with a thick, brownish-orange, velvety pile. The female is destitute of this horn.

HERCULES, PILLARS OF. [GIBRALTAR.]

HERDER, JOHANN GOTTFRIED VON, was born in 1744, at Morungen in East Prussia, where his father kept a little girl's school. The only books he was allowed to read were a Bible and Hymn-book, though he secretly turned his attention to other works. He gained the acquaintance of persons who appreciated him, and procured him a place as instructor in the Friedrich's College at Königsberg. With the most indefatigable industry he studied philosophy, natural science, history, and languages, and in 1764 became assistant at the cathedral school at Riga, to which office that also of preacher was attached. Though his sermons were greatly admired, he soon left the situation, as he desired to study the world at large. He accordingly went to France, and was there chosen by the Prince of Holstein-Oldenburg as his travelling companion. He would have gone from France to Italy had he not been arrested by a complaint in his eyes at Strasburg, where he first became acquainted with Göthe. In 1775 he became theological professor at Göttingen. He died in 1803.

The writings of Herder fill about sixty volumes, and are on the greatest variety of subjects. As a theologian he has gained celebrity by his 'Spirit of Hebrew Poetry;' as a philosopher, as the author of the 'Philosophy of the History of Man.' His collection of popular ballads of all nations has a high reputation.

HERDERITE, a right rhombic prismatic crystal, with a conchoidal fracture, a grayish colour, and nearly transparent.

HEREDITAMENT. [DESCENT.]

HEREDITARINESS. A tendency to certain diseases, as gout, consumption, cancer, insanity, &c., is often transmitted from parents to their offspring. Long life, a robust frame, and good health are also inherited by many children from their ancestors. Unusual peculiarities, special marks, and deformities such as moles, harelip, growth of hair in unusual places, more or less toes or fingers than ordinary, and malformations, may generally be traced to hereditary influence. But this tendency is especially distinguishable in insanity, and it is believed that a large proportion of cases may be traced to this cause. It

would seem that an unhealthy organization of the brain, or bodily qualities incompatible with sound mental vigour, are transmitted, and, in consequence, the heirs are not able to withstand the causes of insanity so well as those of a good constitution and sound mental capacity would do. For many years past an ordinary defence of murderers has been that of insanity; and evidence is called to prove that some of the prisoners' ancestors or relatives have been the victims of mental disease.

HEREFORD, an ancient city, and parliamentary and municipal borough, is situated on the left bank of the Wye, 134 miles W.N.W. from London by road, and 144 by the Great Western Railway. The city, as a municipal borough, is divided into three wards, and is governed by six aldermen and eighteen councillors. The parliamentary borough returns two members to the House of Commons. The municipal and parliamentary boundaries are identical. At the census of 1861 the population was 15,585: in 1851 it was 12,108. The number of voters on the register in 1864 was 1080. Two members have been returned to the House of Commons for Hereford since the time of Edward I. The city is a polling place and the chief place of election for the county.

In early times this city was important as a garrison to restrain the Welsh. The castle consisted of two wards of different dimensions, having a keep within the smaller: the Wye formed its defence on the south side; on other points it was defended by moats. In 1652 the parliamentary commissioners returned it as 'ruinous,' and its materials worth no more than 85*l*. The principal events of its history are its pillage by the Welsh in 1055; its capture by King Stephen in 1141; the execution of Owen Tudor in 1461; the surrender of the city, in 1643, to the parliamentary troops headed by Sir William Waller; and the siege of Hereford by the Scotch under Lord Leven. In and adjoining the city there were formerly establishments of gray friars, black friars, and knights-hospitaller of Jerusalem.

Hereford is situated in a broad, fertile, and well-cultivated valley, and at sufficient elevation above the river Wye to be free from fogs and damp. The principal streets are broad and straight, and have all been macadamized. The private houses, with few exceptions, are built with red brick, and the public buildings of stone. The shire-hall was built after a plan of Sir Robert Smirke, and is remarkable for its unassuming beauty and good arrangement. Within the last few years the town has been greatly improved by the erection of a new market-house with clock-tower, new and extensive cattle market, several large and handsome buildings, &c. The town-hall, a large wood and plaster building supported by oaken pillars, was pulled down in 1861. The union workhouse stands just beyond the north-east limits of the city. The county gaols are in the same neighbourhood. There are several hospitals or almshouses, and some important and well-conducted free schools. The principal churches are those of All Saints, St. Peter, St. Nicholas, and St. John. In addition to the churches belonging to the establishment, there are places of worship for the principal denominations of dissenters.

A triennial musical festival is held in Hereford. The episcopal palace is ancient, and surrounded by

large gardens; the college forms a quadrangle. The total value of the numerous charities in the town is 25217; besides 4360 loaves distributed by the dean and chapter. There are manufactures of gloves, hats, flannels, and cutlery; and a trade in cider, hops, corn, wool, bark, and timber. Coals are chiefly obtained from Abergavenny; and railways connect the city with Shrewsbury, Worcester, Gloucester, and Monmouth, from thence to every part of the United Kingdom. The October fair held here is the largest in England for cattle and cheese. Hereford was the birthplace of Nell Gwynn and David Garrick.

Hereford Cathedral stands upon the south side of the city, not very far from the Wye. The date of the original building is fixed at 825; the whole was rebuilt by Bishop Athelstan about the year 1030. This cathedral was entirely demolished in 1055. No renewal was attempted until the latter years of William the Conqueror's reign, when Bishop Lozing and others commenced the present building. In 1786 the western portion of the cathedral fell, and alterations were made; the spire was removed, and a new western end added by Wyatt. It has recently undergone a thorough restoration, under the superintendence of Gilbert Scott, Esq., and is now admitted to be one of the best of its kind—considering its size—in the kingdom. The present length of the entire building is 320 feet, and the height of the central tower 160 feet. The cathedral contains many monuments of great antiquity, some of which are highly ornamented. Attached to it is a chapter-house and library, containing a curious map of the world of the thirteenth century, and other geographical works. For a minute description of this cathedral, see Duncombe's 'History of Herefordshire,' and Britton's 'Cathedrals.'

The diocese of Hereford is one of the most ancient in England, being of British origin, and re-established by the Saxons in 680. It comprises the two archdeaconries of Hereford and Salop, including thirteen deaneries, which extend partly into the counties of Monmouth, Radnor, Stafford, Montgomery, and Worcester.

HEREFORDSHIRE is bounded E. by Worcestershire and Gloucestershire; N. by Shropshire, with a portion of Worcestershire; W. by Radnorshire, Brecknockshire, and a part of Monmouthshire; and S. by Monmouthshire and Gloucestershire. The length, N. to S., is about 40 miles; the breadth, W. to E., 34 miles. The area is 860 square miles, or 534,823 acres. The population in 1861 was 123,712—62,908 males, and 60,804 females—being an increase of 8223 (seven per cent.) on the census of 1851. There were 25,314 inhabited houses, 815 uninhabited, and 170 in course of erection.

Surface, Rivers, &c.—The surface of this county is generally hilly, but the valleys occasionally expand into open plains. The Hatterel range of the Black Mountain, which forms its border on the west-south-west, is the highest land within its limits; there is likewise a third and lower line of hills extending in the same direction from Middlewood to Wormbridge. In the south-west the Saddlebow and Garway are conspicuous; and in the south the hills near Walford and Penyard. The Malvern Hills and the range stretching northward from Stamford Bishop are the principal heights on the eastern boundary. On the

north are the hills of Downton and Leintwardine, together with the range running in a south-west direction from Ludlow. Near the centre of the county, Dinmore, Westhope, and Badnage Hills, with the line on which the circle of firs called Lady Lift stands conspicuous, form the most prominent features.

No large rivers have their source in these hills; the principal streams which water Herefordshire rise in the higher counties of South Wales. They are, the Wye, the Lugg, the Teme, the Arrow, the Frome, the Leddon, the Doyer, and the Munnaw.

The *Wye*, which rises in Cardiganshire, enters Herefordshire on its western side, and after many windings reaches the city of Hereford, and finally leaves the county near the Leys. It is imperfectly navigable throughout the whole of this county. The immediate vicinity of mountains, and the very large surface of country which it drains, cause sudden and frequently destructive floods. For picturesque beauty this river is justly celebrated. Trout, grayling, and salmon are taken. Since the destruction of a weir in the lower part of the river the number of salmon has increased. Neither of the other rivers is navigable to any useful extent; they are chiefly remarkable for their plentiful supply of fish. Two canals have been formed through portions of this county for the conveyance of coal and other heavy goods; and the county is also well supplied with railway accommodation.

Climate, Geology, and Agriculture.—The climate of Herefordshire varies greatly, according to the elevation and exposure. The neighbourhood of Ross and Ledbury, as well as the central portion of the county, enjoys a superior climate to such portions of the north and west as are in the vicinity of Wales; but the general climate of the whole county is remarkably healthy.

Most of the surface of this county belongs to the old red sandstone formation, but the highest points are of the class of Silurian rocks. These are Marcle Hill, near Ross, on the Wye, and the range between Ludlow and Kington. The Black Mountains, on the Breconshire border, are 2545 feet high; and the Wye cliffs are 2000 feet, at Symond's Yat.

The soil consists principally of a deep and heavy loam, with a substratum of clay in some districts, and gravel in others. The whole is very favourable to the growth of trees, especially the apple-tree and oak. In the neighbourhood of towns the land is cultivated chiefly as meadow or pasture. The high lands are generally occupied by oak coppices, which are numerous and extensive. In the lower lands the wheat crop engrosses the farmer's chief attention. Hop-yards are common in the middle and eastern portions of the county.

Of the entire acreage of the county, 470,400 are grass and arable, and about 13,000 acres are devoted to hops. The soil generally is unusually fertile. The apple crop yields about 20,000 hogsheads of cider, mostly of superior quality. Large quantities of pears are grown, and from them perry is made, which is very much drunk in the county. Oak-bark (used in tanning) is also an important production.

The county is celebrated for its breed of cattle, which are red, with white or mottled faces, and occasionally white about the legs. They are generally preferred for grazing, not being good milkers. The

breed of sheep (estimated at 500,000) is almost as celebrated as that of the cattle. Dairy farming is never practised here, and the milk of the cows, which are only kept for breeding, is given to the calves. The oxen are now no longer worked, but are fed at two years old, and sent to market at three. Agricultural horses of average quality are bred in considerable numbers. The north part of the county produces useful riding and coach horses. Pigs are chiefly procured from Wales, whence a large supply of eggs and poultry are also derived.

Divisions and Towns.—Herefordshire is divided into 11 hundreds and 221 parishes. It is in the diocese of Hereford, and in the Oxford circuit. The assizes are held at Hereford. The county returns three members to Parliament, the number of registered electors in 1865 being 7179; the city two; and the borough of Leominster two; making seven in all.

The following are the chief towns, with the population of each in 1861:—

Bromyard is about 13 miles N.E. from Hereford. The town is small and irregularly built, and a considerable proportion of the edifices are of wood. It has a union workhouse, and branch banks. Population, 2995.

Hereford. [HEREFORD.]

Kington is 19 miles N.W. from Hereford. The town is generally well built, and the inhabitants are principally employed in the manufacture of gloves and nails. The town contains a free grammar-school and a charity school. Population, 3076.

Ledbury is 15 miles E. by S. from Hereford. The church is a spacious edifice of Norman architecture. The town, which is situate on a declivity at the southern extremity of the Malvern Hills, contains several alms-houses, and grammar, charity, and national schools. Its trade depends upon the produce of the neighbouring orchards and hop-grounds. The hops, cider, and perry are all of excellent quality. Population of the parish, 5598. Ledbury is on the Hereford and Worcester Railway, and the Hereford and Gloucester Canal. There are manufactures of rope and sacking, and in the vicinity are some good marble quarries.

Leominster, a parliamentary and municipal borough, is 13 miles N. from Hereford. It has sent members to Parliament since the reign of Edward I., and received its charter of incorporation from Queen Mary, for supporting her cause against Lady Jane Grey. The high street of the town is spacious, but many of the other streets are narrow and inconvenient. The church is of considerable antiquity; it is an irregular building, the work of different periods. There are also places of worship for dissenters. The town contains a market-house, house of industry, a gaol, a branch bank, new town-hall and corn exchange, a free grammar-school, and a new school on the national plan. The old town-hall is a singular structure of plaster and timber work, erected in 1663. The municipal borough is governed by four aldermen and twelve councillors. The parliamentary borough returns two members. The municipal and parliamentary boundaries are now identical: population, 5658. In 1864 there were 349 voters on the register for the borough, which is a polling place for the county. There are manufactures of leather, gloves,

hats, and woollens; and the town has a good trade in hops, wheat, wool, and cider. A few miles from Leominster, a modern column indicates the site of the battle of Mortimer's Cross, fought during the wars of the Roses, which raised the Yorkist leader to the throne with the title of Edward IV.

Ross, a market town, is about 14 miles S.S.E. from Hereford. The church is a handsome and spacious structure, with a lofty spire, founded by Robert Betun, bishop of Hereford, in the twelfth century. There are places of worship for dissenters, a union workhouse, charity schools, an alms-house, a dispensary, and other benevolent institutions. Population, 4346. Ross is a polling place for the county. The cider of the vicinity is in high repute. Pope's lines on the 'Man of Ross' have rendered the name of this place familiar to students of English literature. The hero was John Kyrle, a resident during the reigns of William III., Anne, and George I. After visiting the house in which he lived, Coleridge wrote the lines beginning—

'Richer than misers o'er their countless hoards.'

Weobly is 11 miles N.W. from Hereford, and 147 miles from London. The town consists of one principal street, which contains some well-built modern structures. It was formerly a parliamentary borough, but was disfranchised by the Reform Act. Population, 849. It has a free grammar-school, and the remains of a castle famous in the wars of Stephen and the Empress Matilda.

History and Antiquities.—The greater part if not the whole of Herefordshire was comprised in the territory of the Silures, and was conquered by the Roman general, Julius Frontinus, about A.D. 73. A line of Roman and British intrenchments may be traced from the Malvern Hills to Whitbourn, Thornbury, Croft, Brandon (near Leintwardine), and Coxwall Knoll (near Brampton Brian). There are also traces of a camp on the east of Leintwardine, near Downton, and several Roman roads in various parts of the county.

During the Heptarchy Herefordshire belonged to Mercia, and in 680 a synod was held at Hereford, which was the principal town of Mercia in the time of Offa.

The position of Herefordshire relative to Wales subjected it to continual inroads from the Welsh. A considerable part of the county was included in the 'Marches,' a term used to express the frontier in dispute between the Welsh and the English. In spite, however, of repeated defeats of the Welsh, and very severe exactions, attacks continued to be made upon the persons and property of the Marchers; but no event occurred which immediately affected this county, until the crown of England was in dispute between Stephen and Maud, the daughter of Henry I. Geoffrey de Talebot, and Robert, earl of Gloucester, then declared in favour of the empress. Talebot retired to Hereford, but soon quitted it, and the castle of Weobly, which had been garrisoned against Stephen, was totally demolished. Stephen afterwards invested the city of Hereford.

During the troubled times of Edward II. Herefordshire was the scene of many executions. The king's adherents, Hugh Despencer, Balde, and Reding, were executed at Hereford. No particular event occurred by which the county was locally

affected, until the rebellion of Owen Glendwr threw the Marches into confusion. [GLENDRWR.]

During the wars of York and Lancaster Herefordshire did not escape the general commotion. During the civil wars the city of Hereford was garrisoned for the king, but was taken by Sir William Waller. After the battle of Naseby, the king marched to the relief of Hereford, and the Scotch army raised the siege. In the course of the year 1646 the city was taken by surprise, and the whole county was reduced by detachments in the interest of the Parliament, under the command of Sir William Waller and Colonel Birch.

There were several castles in Herefordshire, of which a few ruins remain, but most of them have been demolished. The only druidical remains are a pile of stones, called Arthur's Stone, situated in the parish of Dorstone.

HERESY, HERETICS. The word 'heresy' (from *αἵρεσις*, 'choice') was originally used to express any opinion which a man adopted. Thus it was applied to the philosophic sects of Greece and Rome. (Cicero, 'Paradox, Proöm.') In the New Testament the term often simply denotes a religious party, without implying any censure. (Acts v. 17; xv. 5; xxvi. 5; xxviii. 22.) Josephus calls the three great Jewish sects *heresies*. ('Antiq. Jud.,' xiii. c. 5, s. 9.) But it is also used in the New Testament as a term of reproach. Thus it was applied by the Jews to Christianity (Acts xxiv. 5, 14), and by the apostles to those who resisted their doctrines (1 Cor. xi. 9; Gal. v. 20; 2 Peter ii. 1; Titus iii. 10). The fathers applied the words *heresy* and *heretics* respectively to opinions which were different from what they considered the doctrine of the apostles, and to those who held such opinions, though some of the fathers draw a distinction between *heresy*, as a wilful rejection of the doctrines of Scripture, and errors arising from ignorance or weak judgment. When the creed of the church began to be settled by ecclesiastical councils, all who refused to submit to their decisions were denounced as heretics. They were also called *heterodox*, while those who adhered to the opinions of the church were called *orthodox*, or *catholics*. Heretics were distinguished from unbelievers, inasmuch as they professed Christianity. Heresy must not be confounded with schism: the former relates to doctrine; the latter is any division on points of discipline. The number of heresies mentioned by early ecclesiastical writers is from 80 to 150; but Lardner ('Hist. of Heretics,' i. 5) has shown that many of these ought to be excluded from the list; nor have we any evidence that many of them had numerous followers. The most important of the various sects generally included under the term are treated of under their respective names.

Before the Reformation in England heresy was the holding of opinions contrary to the Catholic faith and the determination of Holy Church: at least this is the definition of heresy in the Statute 2 Hen. IV., c. 15. The court in which a man could be convicted of heresy, according to the common law, was that of the archbishop in a provincial synod. After conviction the criminal was delivered up to the king to do what he pleased with him. If the criminal had abjured his heresy and then relapsed, the king in council, upon a second conviction, might issue the

writ De Hæretico Comburendo, upon which the criminal was burnt alive. One Sawtre, it is said, was the first man burnt alive for heresy in England, and the writ De Hæretico Comburendo was formed in his case.

The 1 Eliz., c. 1, repealed all former statutes about heresy, which was accordingly punished, after the Reformation was fully established, by ecclesiastical censures, and by burning alive a criminal who had been convicted, in the manner above ascribed, in a provincial synod. The writ for burning the heretic could not be demanded as a matter of right, but was left to the discretion of the crown; and both Elizabeth and James I., in their discretion, thought proper to grant the writ. Elizabeth, it is said, burnt alive two Anabaptists, and James burnt alive two Arians.

The Statute of 29 Car. II., c. 9, abolished the writ De Hæretico Comburendo. Heresy is now left entirely to the judicial committee of Privy Council; and the punishment of death in consequence of any ecclesiastical censure was by that act abolished in England. As Elizabeth and James practically showed their approbation of burning heretics alive, so Lord Coke (3 'Instit.,' c. 5) approves of the punishment.

At present the judicial committee of Privy Council punish for heresy, when they do punish, *pro salute animæ*, as it is termed, that is, solely out of regard to the soul of the offender. But it is difficult to say at present what can be called heresy; and perhaps it is difficult to say what is exactly the punishment for it. Indeed, there seems no risk in asserting that much of the jurisdiction of the judicial committee of Privy Council in respect to heresy, whether it shows itself in speaking, writing, or preaching, has been destroyed by the various Toleration Acts.

The history of heresy in England is instructive. The change from burning alive to the almost unlimited expression of opinion on religious matters, is one of the steps in the social progress of England. This has been illustrated in a remarkable way by the recent work 'Essays and Reviews.'

HERETICO COMBURENDO, in the Middle Age, a writ issued against a heretic, by which he was condemned to be burned alive.

HERFORD or **HERVORDEN**, is a town with 10,000 inhabitants, in Prussian Westphalia, situated on the Werra, at its junction with the Aa, in the government of, and sixteen miles S.W. from, Minden. The place is the capital of a circle, and has a large prison, arsenal, gymnasium, six churches, and the central museum of arts, antiquities, and manufactures for the province. Cotton cloth and yarn, leather, tobacco, and linens are made here.

HERIADES, a genus of hymenopterous insects of the section *Melifera* (Latreille), and family *Apidæ*. Body elongated, slender, almost cylindrical, that of the males with a small cavity beneath, near the apex; mandibles triangular; maxillary palpi two-jointed.

The little bees belonging to this genus, we are informed by Latreille, make their nests in holes in old trees. We presume that, as in the genus *Chalostoma*, the holes are made by the bees themselves.

The smallest British species of bee belonging to

the family *Apide* (*Heriades campanularum*) is very common in many parts of England during the summer and autumnal months; it frequents the flowers of the various species of *Campanula*, and is seldom or never found to visit the flowers of any other genus of plants.

HERICOURT. [SAÔNE, HAUTE.]

HERIOT is a feudal service consisting in a chattel which is given to the lord on the death of a tenant, and in some places upon alienation by a tenant. Heriots are either heriots-custom or heriots-service. A heriot due from the dying tenant by reason of his relation of tenant within a particular manor, or other district, is called *heriot-custom*: *Heriot-service* is a heriot due in respect of the estate of the tenant in the particular land held by him.

HERIOT, GEORGE, founder of the excellent hospital in Edinburgh which bears his name, was born in 1563. His father was a goldsmith in Edinburgh, who filled several of the most important civic offices, and represented the metropolis in several Parliaments. George Heriot the younger was bred to his father's occupation, which was at that time highly lucrative, and was connected with the profession of a banker or money-lender. In 1586 he married Christian Marjoribanks, daughter of a respectable burgess. In 1597 he was appointed jeweller to the queen, and shortly after to the king—her majesty's account to him for a space of two years amounted to nearly 40,000*l*. On the removal of the court to England, Heriot of course followed the fortunes of his royal master. He had now accumulated a large fortune, and chose for his second wife Alison, daughter of James Primrose, clerk to the privy council, and ancestor of the earl of Roseberry. But he was deprived of this lady also by her dying in childbirth in 1612, in her twentieth year. 'The loss of his young, beautiful, and amiable partner at a period so interesting,' Sir Walter Scott conjectures, was the probable reason which induced Heriot to devote his fortune to a charitable institution. After leaving considerable sums to his various relations, this munificent philanthropist bequeathed the remainder of his large estate to establish an hospital for the gratuitous education of the sons of Edinburgh freemen. The building—a magnificent quadrangle of the Gothic order—is said to have been designed by Inigo Jones in 1628, but was not completed till 1659. It is under the management of the town council and clergy of Edinburgh. So largely have the funds increased, that they not only support and educate most efficiently one hundred and eighty youths annually, but also maintain in the highest state of efficiency a number of schools in different parts of the city. The founder of this noble charity—'Gingling Geordie,' as King James termed him—was a great favourite with his majesty. An admirable portrait of him has been drawn by Sir Walter Scott in the 'Fortunes of Nigel.'

HERISON, in military matters, a sort of chevaux-de-frise made of one strong beam, with a number of iron spikes which revolve upon a pivot, and always present themselves in front, whichever way the beam revolves.

HERITABLE BOND. [HERITABLE SECURITIES.]

HERITABLE JURISDICTIONS, in Scotch law,

were grants of criminal jurisdiction formerly conferred for distinguished military service, along with the lands to which they were attached, on certain great families, in order to expedite the administration of justice throughout the land. As the lands were made over not only to the grantee, but to his heirs, the jurisdictions annexed to them were consequently heritable. These jurisdictions, becoming in course of time a source of great abuse, were abolished, along with other powers conferred on landed proprietors, shortly after the rebellion of 1745, by the Act 20 Geo. II., c. 43, compensation being given to those who suffered patrimonial loss by the operation of the statute.

HERITABLE SECURITIES, in Scotch law, are various modes in which lands and heritages may be rendered a source of credit to their proprietors. The real right may be constituted by registration of the bond or sasine in favour of the creditor, or be dependent on the force of a condition simply qualifying the right of property. The principal ways in which heritable securities may be created are:—

1. By *wadset*, an *ex facie* irredeemable right in favour of the creditor, but qualified by a separate deed conferring the right of reversion on payment of the debt for which the lands were impledged. This form is now rarely met with in practice.

2. By *real burden* specifically imposed by the disposition upon the lands, and binding upon the disponee and his heirs.

3. By *heritable bond*, a deed in which the debtor binds himself to repay the principal sum with interest, and grants obligation to infest the creditor in an annual rent payable out of the lands, during the non-payment of the principal sum. This security is of the nature of a real burden, and is completed by infestment in the person of the creditor. This term is sometimes, but improperly, applied to—

4. The *bond and disposition in security*, in which, in addition to the above, there is a conveyance of the lands themselves for the creditor's further security.

5. *Absolute disposition and back bond* is a form of security in which the disposition of the lands to the creditor is absolute, qualified only by a personal obligation to restore them on payment of the debt.

ADJUDICATIONS and INHIBITIONS are also of the nature of heritable securities.

HERITOR, in law of Scotland, originally meant the proprietor of a heritable subject, but is now applied to such possessors of lands or houses as are liable in payment of parochial burdens, either for the support of parish schools, the maintenance of the poor, or minister's stipend.

HERM. [GUERNSEY.]

HERMANN, the *Arminius* of the Roman historians, was the son of Sigimer, chief of the Cherusci, and was born about 16 B.C. Having been sent in early youth as a hostage to Rome, he obtained the favour of Augustus, and was inscribed among the Roman knights. On his return to his native country, he conceived the project of delivering it from the Romans. He defeated Varus, the Roman governor in Germany, by which the Romans lost all their conquests beyond the Rhine. After a series of successes against the Romans, Hermann remained unmolested in Northern Germany. Shortly after, however, he was killed by his own relatives, being accused, as it

would seem, of aspiring to absolute dominion. He died at the age of thirty-seven, in 21 A.D., after being for twelve years the leader and champion of Germany.

HERMANNSTADT, a town of Hungary, near the Wallachian frontier, 73 miles S.S.E. of Klausenburg. It is inclosed by walls, and is the head-quarters of the military commandant of Transylvania, the seat of Roman Catholic and Lutheran gymnasia, and a Greek bishop's see. The principal edifices are the Bruckenthal palace, with a library, museum, and theatre; Lutheran, Calvinist, Roman Catholic, and Greek churches; barracks, military hospital, orphan asylum, and many museums. There are also manufactures of linen and woollen fabrics, felt hats, horn combs, earthenware, and leather.

HERMAPHRODITE. [MONSTER.]

HERMAS, a Christian writer of the first century, who is said by Eusebius ('Hist. Eccl.' iii. c. 3) and Jerome ('De Illust. Viris,' c. 10) to have been the same individual whom St. Paul salutes in his Epistle to the Romans (xvi. 14). He was the author of a work entitled 'The Shepherd,' which is frequently quoted with the greatest respect by almost all the early Christian writers. We learn from Eusebius ('Hist. Eccl.' iii. c. 3, 5), and other writers, that it was received by many churches as a canonical work. After the time of Origen, who considered it of divine authority, its canonical authority appears to have been generally denied.

'The Shepherd' contains no express citations of any books of the Old or New Testament. The work was originally written in Greek, but there is only an ancient Latin version of it extant in the present day. There is an English translation by Wake, London, 1693 and 1710.

HERMENEUTICS, the science of interpretation, especially applied to the meaning of the Scriptures. It differs from exegesis, in that its true province is the discovery of the real meaning of the text, while the province of exegesis is the exposition of this meaning, and its application to the wants of mankind. The inquiries of hermeneutists are simply literary, dealing with the signification of words and idioms, the object and circumstances of writing, the credibility and character of the writer, and all that concerns the text and the interpretation of the Holy Scriptures. This branch of literature has received more attention of late than perhaps at any previous time; and although some (so-called) eminent critics of the present day have succeeded marvellously in 'darkening counsel by words without knowledge,' the result on the whole has been favourable to the elucidation of the text of Scripture.

HERMES, an ancient Greek divinity, known to the Romans as *Mercurius*, was, according to Hesiod ('Theog.' 942), the son of Zeus and Maia, the daughter of Atlas. The attributes of this deity are numerous and of opposite kinds; but it appears probable that he was originally considered to preside over flocks and herds.

In Homer the name of this deity is usually *Hermias*. He is represented as the messenger of Zeus and the gods, and he conducts the souls of the departed to Hades. In later times he was regarded as the god of eloquence; the inventor of the lyre and weights and measures; the patron of merchants and

of gain, and even of thieving; and the protector of heralds, poets, musicians, and wrestlers. Statues of Hermes, which were originally square blocks with a carved head upon them, were placed in the doorways of most private houses and temples at Athens. (Thucyd., vi. 27.) They were also erected where several roads met, to point out the way, and in the gymnasia, or public places of exercise.

Hermes is usually represented with a chlamys, or cloak; a petasus, or winged cap; talaria, or winged sandals; and a caduceus, or wand, with two serpents twined about it, in his hand.

The Egyptian god Thoth was also called Hermes by the Greeks. A great number of philosophical and astrological works, purporting to be written by the Egyptian Hermes, were in circulation in the early ages of the Christian era. Most of them appear to have been written at Alexandria by Gnostic Christians, or philosophers of the Aristotelian or of the new Platonic schools. A few of these works are still extant.

HERMES, GEORG, the founder of a philosophical school of Roman Catholic theology, was born on the 22nd of April, 1775, at Dreyerwalde, in Westphalia. He became a pupil of the gymnasium at Rheina, and in 1792 entered the theological faculty at Münster. In 1798 he was appointed teacher at the gymnasium of Münster, and all his exertions henceforth were directed towards restoring, on a firm basis, that which had been demolished by Kant's 'Criticism of Pure Reason.' In 1807 he was appointed professor of theology at Münster, and in 1819 filled the same office at the University of Bonn. His lectures attracted students not only from all parts of Catholic Germany, but the king of the Netherlands sent a large number of young men to Bonn for the special purpose of pursuing their studies under Hermes. In the enjoyment of the highest esteem both of his colleagues and pupils, he died at Bonn on the 26th of May, 1831.

The only work that Hermes published bears the title 'Einleitung in die Christ-Katholische Theologie,' Münster, 1819, 8vo.; a second edition appeared in 1831. Soon after the elevation of Droste-Vischering (between whom and Hermes considerable ill-feeling existed) to the archbishopric of Cologne, reports were made to Rome about the infidel tendency of the work of Hermes, in which the objectionable point was his principle, that reason or philosophy must in the first place prove the reality of a divine revelation, and in the second, the truth of the Roman Catholic system.

On the 26th of September, 1835, the pope issued a brief against the work of Hermes, and the consequence was a rupture between the courts of Berlin and Rome, and a long controversy, the best exposition of which may be found in Elvenich's 'Der Hermesianismus und sein Römischer Gegner Peronne,' Breslau, 1844, 8vo.

HERMIAS. [ARISTOTLE.]

HERMIT, more properly *Eremit*, from the Greek, *ἐρημίτης*, signifying an inhabitant of the desert, is the name given to such religious persons as retired from society without becoming members of any monastic community. [ANCHORET; MONACHISM.]

HERMIT-CRAB. [PAGURIANS.]

HERMITAGE, the solitary cell or habitation of

a hermit, or sometimes the term is used to denote the dwelling-places of a community of hermits. These have often exercised considerable influence on the surrounding districts, and frequently laid the foundation of towns, cities, and ecclesiastical establishments.

HERMOGENES was a native of Tarsus, and lived under Marcus Aurelius. At the age of fifteen, it is said, he was professor of Greek eloquence at Rome, where his lectures were attended by that emperor. At the age of eighteen he wrote his work on the oratorical art, consisting of four sections. His illustrations and quotations are chiefly taken from the 'Orations' of Demosthenes. The work of Hermogenes was held in high esteem, and became a standard book in all Greek schools. It has been repeatedly printed in the Greek text, and Gaspard Laurent published it with a Latin translation and commentaries, 8vo., Geneva, 1614. Hermogenes had joined to his work a book of 'Progymnasmata,' or specimens of oratorical exercises, which Priscianus translated into Latin, the Greek text of which remained inedited till the end of the last century, when it was first published by A. H. L. Heeren, and has since been republished by Veesenmeyer, 8vo., Nürnberg, 1812, and by others.

HERMOGENES, a heretic of the early church, against whom Tertullian has written a treatise, was most probably a native of Africa, and flourished, according to Basnage and Le Clerc, in 168. We have no account of any of his writings, though it may be inferred from the arguments of his opponents that he was an author. For a further detail of his opinions see Lardner, 'Hist. of Heretics,' ch. xviii.

HERMOSILLO, a city of Mexico, with a population of 15,000. It is the centre of the commerce and mineral riches of the state of Sonora, and has some brandy distilleries, schools, prisons, a hotel, and a mint. The principal exports are maize, cotton, and fruit. Cotton goods are manufactured.

HERNANDIA'CEÆ, a natural order of incomplete exogenous plants. It contains only two genera, *Hernandia* and *Inocarpus*. *Hernandia*, the typical genus of this order, was named after Hernandez, a naturalist sent out to Mexico by Philip II. of Spain. *H. sonora* is a tall erect tree, a native of the various parts of the East and West Indies, and has obtained its name *sonora* from the noise made by the wind in whistling through its persistent involuclcs. The bark, the seed, and the young leaves of this tree are slightly cathartic. The juice of the leaves is employed as a depilatory. It destroys the hair wherever it is applied, and this without producing pain.

HERNANI. [BASQUE PROVINCE.]

HERNIA, from *ἑρως*, 'a branch,' signifies the protrusion of any organ from its natural position in the body, as *hernia cerebri*, *hernia pulmonis*, when the brain or lung protrudes through an aperture in the skull or the chest. But when used alone this term means what is commonly called a *rupture*, that is, the protrusion of any portion of the intestinal canal from the cavity of the abdomen.

Herniæ sometimes form without any evident cause, the intestine being gradually protruded; but more frequently they result from some violent bodily exertion, as lifting heavy weights, excessive coughing or straining; or from sudden jarrings or shocks, as

in jumping or falling; or from blows on the abdomen.

The general characters distinguishing a hernia are, a tumour, neither red nor hot, and often not painful, situated at some part of the abdomen, most frequently in or near the groin; largest when the patient stands up, and often disappearing entirely when he lies down; distended by coughing or other violent expiration, and liable to variation in size by exercise or rest, by abstinence or taking food; often producing disorders of the digestive canal, as flatulency, colic, &c. In the cases in which the hernia forms suddenly, as in consequence of a great exertion, the patient feels as if something had given way at the groin or other part of the abdomen, and on putting his hand there he feels a tumour which may vary in size from that of a nut to that of his fist, is elastic, hard, and tense, and soon after the accident becomes painful and tender. In the other class of herniæ the tumour forms almost imperceptibly to the patient, and grows larger regularly but slowly. If a hernia can be returned into the abdomen at pleasure, it is not by itself a dangerous disease; but if it becomes strangulated, that is, if the intestine is so constricted by the parts through which it has passed that its contents cannot pass through it, and its vessels are so much compressed that active inflammation is excited, it constitutes one of the most serious accidents to which the human body is liable. The symptoms indicating strangulation of the intestine are obstinate constipation of the bowels; pain and tenderness of the tumour, and spreading from it over the whole surface of the abdomen; extreme restlessness and languor; nausea and vomiting; a hard, small, and rapid pulse; thirst and coldness of the limbs. If the hernia be not reduced, these symptoms will regularly increase, till mortification of the intestine ensues, and (except in some most rare cases) death rapidly follows.

Several forms of hernia are recognized by surgeons according to the part of the abdomen through which the bowel protrudes. The most common are the Inguinal, Femoral, and Umbilical herniæ.

Whatever be the situation or condition of a hernia, it should be at once, if possible, reduced; the patient should go to bed, and after lying a short time on his back, with his knees raised, the intestine will often of itself recede into the abdomen, especially if it have been frequently protruded; but if it do not, then it should be worked into its place by means of the hands. If this fail, there are several auxiliary means that may be employed, of which a selection must be made according to the circumstances of each individual case. The warm bath should be first tried in all cases. The abstraction of blood will be useful, not only by the faintness which it produces being a favourable state for reducing the hernia, but by its relieving the inflammation which always arises when the intestine is strangulated, and by checking it in its fatal progress. If the warm bath and bleeding fail, the patient should be placed between warm blankets to recover from their depressing effects, and no more manual attempts should be made for some time. The next means employed should be the continued application of cold by ice or a rapidly evaporating lotion laid over the tumour. Should this fail, and the symptoms of strangulation be increasing,

some surgeons recommend tobacco enema. Great caution is necessary, however, in employing it, and by many it is not had recourse to at all. If the tobacco enema is used, a last attempt at reduction should be made whilst the patient is under its influence. The operation consists in cutting down upon the strangulated bowel, and carefully enlarging the opening through which it has protruded, so that it may return with facility, and if this attempt is still unsuccessful, an operation must be resorted to.

When a hernia has been completely reduced, its recurrence must be prevented by wearing a truss.

HERO, HEROIC, HEROISM are used, in their common English sense, to denote an unusual, and, as it were, superhuman degree of bravery and virtue. This meaning flows directly from the original Greek word, which denoted (at least in the times subsequent to the Homeric poems) a person intermediate between gods and men, and usually of divine descent on at least one side. Such were worshipped with divine honours by those cities and races of men which claimed them as their founders or ancestors. This divine origin, however, was not essential; thus Philippos of Crotona, who fell in battle against the Phœnicians and Egæstæans, was made a hero for his beauty; a heroum, or shrine, was built on the spot where he was buried, and sacrifices were offered to him. (Herod., v. 47.) At a later age, Arátus and Brásidas were worshipped as heroes at Sicyon and Amphípolis; and the Athenians slain at Marathon received similar honours. The Heroic Age, properly so called, appears, however, to have terminated with the immediate descendants of the Greeks who returned from Troy. In Homer the word hero occurs frequently, but in quite a different sense: it is applied collectively to the whole body of fighters, Argeii, Danaí, and Achæi, without reference to individuals of peculiar merit, and indeed often appears to be used for little more than an expletive, when he, or the man, or the soldier, would have done equally well. Indeed, the application of the word is not even limited to warriors, but is applied to heralds, wise counsellors, kings, &c.

The promiscuous (or Homeric) use of the word hero disappeared in the age succeeding the Homeric poems. When the Greeks looked back to the warlike legends of the earlier race who had borne the title, the lays, exploits, and persons were called heroic; and from the combined effect of poetical exaggeration, reverence for antiquity, and traditions of national descent, the more modern Greek use of the word arose, carrying with it notions of mythical dignity, and of superiority to the later race of mankind.

HERO, or HERON. There are two of this name, both writers on mechanical subjects. Hero the Elder was the pupil of Ctesibius, and lived at Alexandria about B.C. 100. The country of the younger Hero is uncertain, but he is supposed to have lived about 610.

Hero the Elder must have enjoyed great reputation, since he is mentioned by Gregory Nazianzen with Euclid and Ptolemæus: but he is now principally known by some fragments of his writings on mechanics, which are to be found in the 'Mathematici Veteres,' Paris, 1693. Hero the Younger wrote on Practical Geometry and Military Science.

HEROD (HERO'DES), the name of several Jewish princes:—

I. HEROD THE GREAT was the second son of Antipater, by whom he was appointed governor of Galilee at the age of twenty-five. In B.C. 40, when the Parthians invaded Judæa, Herod escaped to Rome, where, by the influence of M. Antonius, he was appointed king of the Jews; but the Roman generals in Syria assisted him so feebly, that it was not till the end of the year 38 B.C. that Jerusalem was taken by Sossius. The commencement of Herod's reign dates from the following year. In the year 38 he had married Mariamne, the granddaughter of Hyrcanus, hoping to strengthen his power by this match with the Asmonean family, which was very popular in Judæa. He made Aristobólus, the brother of Mariamne, high-priest, but shortly after Aristobólus was secretly put to death by the command of Herod. Cleopatra, queen of Egypt, having been informed of the murder, Herod was summoned to answer the accusation before M. Antonius, whom he pacified by liberal bribes. When setting out to meet Antonius, he had commanded his brother Joseph to put Mariamne to death in case he should be condemned, that she might not fall into the power of Antonius. Finding on his return that Joseph had revealed this order to Mariamne, Herod put him to death. In the war between Octavianus (afterwards the Emperor Augustus) and M. Antonius, Herod favoured Antonius. After the battle of Actium he went to meet Octavianus at Rhodes, by whom he was well received, and confirmed in his kingdom. Before he set out, he had imprisoned Mariamne and her mother Alexandra, commanding their keepers to kill them, if he should be put to death by Octavianus. On his return, Mariamne reproached him with his intentions towards her, which she had again discovered. This led to an estrangement between Herod and his wife, and he finally accused her of adultery. She was condemned and executed. After her death Herod suffered the deepest remorse. His open disregard of the Jewish law increased the hatred of the people towards him. To secure himself against rebellion he fortified Samaria, which he named Sebaste, and built Cesarea, and other cities and fortresses. In the year 17 B.C. he began to rebuild the temple at Jerusalem. The work was completed in eight years, but the decorations were not finished for many years after. (John ii. 20.) Herod's power and territories continued to increase, but the latter part of his reign was disturbed by the most violent dissensions in his family. He died in March, B.C. 4, in the thirty-fourth year of his reign and the seventieth of his age.

The birth of Jesus Christ took place in the last year of Herod's reign, four years earlier than the era from which the common system of chronology dates the years A.D. (Clinton's *Fasti Hellenici*.)

II. HEROD ANTIPAS, son of Herod the Great, was appointed by his father's will tetrarch of Galilee and Peræa. About A.D. 26 he divorced the daughter of Aretas, king of Arabia, and married his sister-in-law Herodias. John the Baptist having remonstrated against this marriage, was imprisoned, and afterwards put to death. (Luke ii. 19, 20; Mark vi. 17–29.) About the same time Aretas marched against Antipas and defeated him. In A.D. 39

Antipas was accused by Agrippa, king of Judæa, of a secret understanding with the Parthians, and was banished by Caligula to Lyon.

III. HEROD AGRIPPA, son of Aristobulus, and grandson of Herod the Great, after experiencing many vicissitudes in early life, was appointed, upon the accession of Caligula, king of the dominions formerly held by Philip, namely, Gaulanitis, Batanæa, and Trachonitis, to which Caligula added the tetrarchy of Lysanias; and afterwards, when Antipas was banished, the tetrarchy of Galilee and Peræa. Claudius added Judæa and Samaria to his dominions. His government was popular with the Jews, to please whom he persecuted the Christians. (Acts xii. 1-3.) He died of a loathsome disease at Cesarea, in the third year of his reign over all Palestine, A.D. 44. (Acts xii. 20-23.)

IV. HEROD AGRIPPA, son of the above, was seventeen years old at the time of his father's death. Upon the death of Herod, king of Chalcis, four years afterwards, Claudius bestowed that kingdom upon Agrippa. He did not leave Rome till A.D. 53, when Claudius gave him the tetrarchies of Gaulanitis, Batanæa, and Trachonitis. His dominions were enlarged by Nero. It was in A.D. 60 that the trial of Paul before Agrippa took place. (Acts xxvi.) Agrippa exerted himself to keep down the spirit of revolt among the Jews. When war broke out, Agrippa joined the Romans. After the taking of Jerusalem, he retired with his sister Berenice to Rome, where he died at the age of about seventy years.

(Josephus, *Antiquities of the Jews*, and *Jewish War*; Jahn's *Hebrew Commonwealth*; Prideaux's *Connection*.)

HERODES, TIBERIUS CLAUDIUS ATTICUS, a native of Marathon, in Attica, and of an illustrious family, was born under the reign of Trajan. He inherited from his father a very large property. Herodes was educated by the best teachers of his time; and he became an accomplished scholar, rhetorician, and philosopher. Having removed to Rome, his wealth, his connections, and his extemporary eloquence, which is spoken of as wonderful, gave him great importance, and he was made consul with C. Bellicius Torquatus in 143. Herodes married, at Rome, Annia Regilla, of an illustrious and wealthy family. She bore him four children, and died while pregnant of the fifth. His brother-in-law suspected Herodes, who was of a violent and jealous temper, of foul treatment of his wife, and he brought him to trial on the charge of murder; but Herodes was acquitted. Herodes displayed an excessive grief for the loss of his wife, and he dedicated her estate to Minerva and Nemesis. An inscription, which he wrote, or caused to be written, in Greek hexameters, records the fact. There is another inscription, likewise in Greek verse, in which the poet invites the Roman women to honour the memory of Regilla, descanting upon her beauty, virtue, and high lineage. These two inscriptions, which are on two large slabs of Greek marble, have given much employment to critics. (Visconti, *Iscrizioni Tropee ora Borghesiane*, 4to., Rome, 1794.) Herodes died at Marathon, in the seventy-sixth year of his age, towards the end of the reign of Aurelius, or the beginning of that of Commodus.

He erected monuments, temples, baths, and aqueducts in Italy, Greece, and Asia. Pausanias (vii. 20) mentions an Odeon, or Music Theatre, at Athens, as built by him, called the Theatre of Regilla, after his wife: he also embellished the Stadium near the Ilissus, which was originally constructed by the orator Lycurgus, 350 B.C.

HEROD'IANUS ('*Ῥωδιανός*, Matt. xxii. 16; Mark iii. 6; xii. 13; see also Mark viii. 15), were in all probability a political party in Judæa, who were anxious to preserve the government in the hands of Herod's family. Many critics consider the Herodians to have been a religious sect. In their religious opinions they probably belonged to the sect of the Sadducees; since that which is called by Mark (viii. 15) 'the leaven of Herod,' is styled by Matthew (xvi. 6) 'the leaven of the Sadducees.'

HERODIANUS, a Greek author, who wrote a history, in eight books, of the Roman emperors who reigned successively in his lifetime, beginning with the death of Marcus Aurelius in 180, and ending with the accession of the younger Gordianus in 238. This history comprehends a period of little more than half a century, within which lived the emperors Commodus, Pertinax, Julianus, Niger and Albinus, Septimius Severus, Caracalla and Geta, Macrinus, Elagabalus, Alexander Severus, Maximinus, the two Gordiani, and Balbinus. The style of Herodianus is plain, and his narrative in general seems written in a fair spirit. He is the last of the Greek historians of antiquity who lived before the partition of the Roman Empire. Among the editions of his history that of Irmisch, in 5 vols. 8vo., Leipzig, 1798-1805, in Greek and Latin, contains numerous notes, chronological and genealogical tables, and several copious indexes. The last edition and the best text is by Bekker, Berlin, 1826, 8vo. There are several German translations of Herodian.

HERODOTUS, a native of Halicarnassus, a Dorian city in Caria, was born about B.C. 484. If the passages in his own History (i. 130; iii. 15) were written by himself, he was probably alive in B.C. 408. He was the son of Lyxus and Dryo, and of an illustrious family in his native state. Not liking the government of Lygdamis, who was tyrant of Halicarnassus, he retired for a time to Samos, where he is said to have cultivated the Ionic dialect of the Greek, which was the language of that island. Before he was thirty years of age he joined in an attempt, which proved successful, to expel Lygdamis. Herodotus again left his native country, and joined, as it is said, a colony which the Athenians sent to Thurii, in South Italy (B.C. 443.) He is said to have died at Thurii, and was buried in the Agora, or Public Place. Herodotus was a traveller and observer, as well as an historian. The extent of his travels may be ascertained pretty clearly from his History. The story of his reading his work at the Olympic games, which has found its way into most modern narratives, has been well discussed by Dahlmann, and we may perhaps say disproved. (*Aus seinem Buche sein Leben*, Altona.)

Herodotus makes no display of the great extent of his travels. He frequently does not say that he was at a place, but he uses words which are as conclusive as any statement. He describes a thing as standing behind the door (ii. 182), or on the right hand as

you enter a temple (i. 51); or he was told something by a person in a particular place (ii. 28); or he uses other words equally significant. In Africa he visited Egypt, from the coast of the Mediterranean to Elephantine, the southern extremity of the country (ii. 29); and he travelled westward at least as far as Cyrène (ii. 32, 181). In Asia he visited Tyre, Babylon, Ecbátana (i. 98), and probably Susa (v. 52-54; vi. 119). He also visited various parts of Asia Minor, and probably went as far as Colchis (ii. 104). In Europe he visited a large part of the country along the Black Sea, between the mouths of the Danube and the Crimea, and went some distance into the interior. He seems to have examined the line of the march of Xerxes from the Hellespont into Attica, and certainly had seen numerous places on this route. He was well acquainted with Athens (i. 98; v. 77, &c.), Delphi, Dodona, Olympia (ix. 81), Tegea (i. 66), Thasos, Delos, Zacynthus (iv. 195), and numerous other places in Greece. That he had visited some parts of South Italy is clear from his work (iv. 99; v. 44, 45). The mention of these places is sufficient to show that he must have seen many more.

The Nine Books of Herodotus contain a great variety of matter, the unity of which is not perceived till the whole work has been thoroughly examined. But the subject of his History was conceived by the author both clearly and comprehensively. 'The object of the inquiries (for so we may render the word *ιστορίαι*) of Herodotus of Halicarnassus is this, that the acts of man may not be forgotten through lapse of time, and that great and wondrous achievements, performed partly by Greeks and partly by Barbarians, may not be without their fame; and also how it came to pass that Greeks and Barbarians waged war together' (i. 1). His object then was to combine a general history of the Greeks and the Barbarians (that is, those not Greeks) with the history of the wars of the Greeks and the Persians. Accordingly, in execution of his main subject, he traces the course of events from the time when the Lydian kingdom of Croesus fell before the arms (B.C. 546) of Cyrus, the founder of the Persian monarchy, to the capture of Sestos (B.C. 478); an event which crowned the triumph of the Greeks over the Persians.

The great subject of his work, which is comprised within the space of sixty-eight years, not more than the ordinary term of human life, advances with a regular progress and truly dramatic development, from the first weak and divided efforts of the Greeks to resist Asiatic numbers, to their union as a nation, and their final triumph in the memorable fights of Thermópyle, Sálamis, and Plataea. But with this subject, which has a complete unity well maintained from its commencement to its close, the author has interwoven, conformably to his general purpose, and by way of occasional digression, sketches of the various peoples and countries that he had visited in his widely extended travels. His predecessors in historical composition appear generally to have chosen subjects of a limited nature, partaking chiefly of the character of local annals. Herodotus chose for his subject a series of events which concerned the universal Greek nation, and not them only, but the whole civilized world; and by the way in which he

executed his great undertaking he has earned the honourable and well-merited appellation of the Father of History.

The style of Herodotus is simple, pleasing, and generally perspicuous; often highly poetical both in expression and in sentiment. But it bears evident marks of belonging to a period when prose composition had not yet become a subject of art. His sentences are often ill-constructed and hang loosely together; but his clear comprehension of his own meaning, and the sterling worth of his matter, have saved him from the reproach of diffuseness and incoherence.

There is no translation of Herodotus which has yet done justice to the original; and no commentary has yet exhausted one-tenth of the matter which admits and requires illustration.

The first edition of Herodotus was the Latin translation of L. Valla, Venice, 1474, folio. The most complete edition of Herodotus is by J. Schweighäuser, Strasburg, 1816, 6 vols. 8vo. 'The Apology of Herodotus,' by H. Stephens, prefixed to his corrected edition of Valla's translation, Frankfort, 1595, is a clever and amusing vindication of Herodotus against the charge of falsehood, made on the ground that many of his stories were so singular and improbable. L'Archer's French translation, Paris, 9 vols. 8vo., with the Commentary, is a useful book. There are various English translations. That by Beloe is as bad as a translation can be.

HEROIC VERSE in its ancient sense means that which was the vehicle of Greek and subsequently of Latin epic poetry, of which the actions of the heroes were the appropriate subject. In English our common ten-syllable couplet passes under this name, chiefly, it should seem, because it is the measure into which the epics of antiquity have been most frequently translated. The Alexandrine of twelve syllables, however, has been also used by our elder writers for this purpose, as by Chapman in his translation of the *Iliad*.

HERONS. Under the head of *Echassiers* (*Grallatores*), Cuvier distinguishes the following groups, or, as he terms them, families, viz., the *Brevipennes*, the *Pressirostres*, the *Cultirostres*, the *Longirostres*, and the *Macroactyles*.

The *Cultirostres* include the Cranes, the Boatbills, the Herons, the Storks, the Jabirus, the Ombrettes, the Tantal, the Openbeaks, and the Spoonbills.

Mr. Vigors considers that the *Grallatores* are naturally divided into the following five families: *Gruidae*, *Ardeidae*, *Scolopacidae*, *Rallidae*, and *Charadriidae*, an arrangement which is adopted by Mr. Selby, and many other ornithologists.

For other views relative to the arrangement of the *Grallatores*, we may refer the student to Willughby, Ray, Latham, Duméril, Illiger, Vieillot, De Blainville, Swainson, the Prince of Canino, and other zoologists.

Under this title of *Hérons*, it is our purpose to treat of the true Herons, the Spoonbills, the Storks, and the Cranes.

HERONS.

Bill long, stout at the base, and sharp pointed; gape extending beneath the eyes; a little nasal fossa prolonged into a furrow extending almost to the point of the upper mandible; lores naked. The

internal edge of the middle toe pectinated. Tarsi very long, scutellated in front, reticulated posteriorly. Neck elongated. The stomach is capacious, and capable of considerable distension. The food of these birds consists of fish, reptiles, and such small mammalia as shrews, water rats, &c. Some, as the Common Heron, are gregarious during the breeding season, and build in lofty trees; others are altogether solitary. All are reclusive, frequenting wide marshes, and the banks of rivers, which supply them with food. Geographical range universal.

As examples, we may mention the Common Heron (*Ardea cinerea*), the Crested Purple Heron (*Ardea purpurea*), the Great White Heron (*Ardea alba*), the Little Egret Heron (*Ardea gazetta*), the Buff-backed Heron (*Ardea russata*), the Squacco Heron (*Ardea ralloides*), the Bittern (*Botaurus stellaris*), and the Night Heron (*Nycticorax Europeanus*), all claiming to be regarded as British birds.

The Common Heron is, in the opinion of Belon and some others, the *Erodias* (Erodias) of Aristotle, but we do not consider this as certain. But the bird is, without doubt, the *Ardea* of the Romans, and is the *Beccapesce*, *Airone*, *Ocacicogna*, and *Garza* of the modern Italians; *Garza* of the Spaniards; *Reyger* and *Rheier* of the Germans; *Héron* of the French; and *Common Heron*, or *Heronshaw*, of the British.

Common Heron (*Ardea cinerea*).

This species is too generally well known to need a detailed description.

In the days of falconry the heron was greatly valued, and the destruction of its eggs was visited with a penalty of twenty shillings; moreover, it held as high a place at the tables of the great as it did in the field. Its flesh is now disregarded, though according to Mr. Selby it is far from being despicable.

SPOONBILLS.

In this group the bill is very singularly formed, being spatulate at the extremity. These birds are all included under one generic head, *Platalea*.

Generic Character.—Bill very long, strong, very much flattened, point dilated and rounded into the form of a spoon or spatula; upper mandible channelled, transversely furrowed at its base. Nostrils at the surface of the bill approximated, oblong, open,

bordered by a membrane. Face and head partially or entirely naked. Tarsi long, strong; three toes anteriorly united up to the second joint by membranes or webs, posterior toe touching the ground. Wings moderate, ample; the first quill nearly as long as the second, which is the longest.

Habits of the Genus.—The spoonbills live in society in wooded marshes, generally not far from the mouths of rivers, and are rarely seen on the seashore. Their food consists of small fishes, spawn, and small fluviatile testaceous molluscs, as well as small reptiles and aquatic insects. According to circumstances, they build their nests either in high trees, in bushes, or among rushes. Their moult is simple and ordinary, but the young bird does not take the confirmed livery of the adult till the third year; the bill is gradually developed, and appears covered with a membrane. The crest makes its appearance at the second year. The sexes have external distinctions, but the characters are but slightly marked. (Temminck.)

We select as an example the Common White Spoonbill, *Platalea leucorodia*, Linn.

Spoonbill (*Platalea leucorodia*).

This species is, there can be little doubt, the *λευκωρῳδίας* (Leucorodius) of Aristotle ('Hist. Anim.,' book viii., c. 3). It is the *Becquaroueglia* (Belon) and *Cucchiaronne* (Bonaparte) of the Italians; *Pale*, *Poche*, *Cueiller*, *Truble* (Belon), and *Spatule* of the French; *Weisser Laffler* and *Laffel Gans* of the Germans; and *Spoonbill* and *White Spoonbill* of the British.

This bird is a rare visitant to the marshes of our island, but is common in many parts of the adjacent continent, and nowhere more so than in Holland, arriving there as a summer resident, and departing southwards, often with the stork, in autumn.

In this bird, and probably other species, the trachea makes a double flexure before entering the thorax, in which peculiarity it evinces an analogy to the cranes.

The eggs of the Common White Spoonbill are three or four in number, generally white, but sometimes marked with spots of reddish brown. The nest is made either in trees or among rushes or reeds.

STORKS.

The Storks are included by most naturalists under one generic head, *Ciconia*. Linnæus, Cuvier, and others separate from this the genus *Mycteria*,

distinguished by the somewhat upward flexure of the long and powerful beak; these are *Les Jabirus* of Cuvier.

There can be no hesitation as to the propriety of placing the huge *Marabous*, distinguished by their naked neck and head, and by a sort of naked pre-sternal pouch, in a distinct genus, to which the name of *Leptoptilos* has been given, and we regard the genera *Scopus*, Brisson (*Les Ombrettes*, Cuvier), and *Anastomus*, Illiger (*Les Becs ouverts*, Cuvier), as well established. Hence the generic characters of *Ciconia* will refer only to a limited number of species, of which the White Stork may be regarded as the type.

Genus *Ciconia*.—*Generic Character*.—Bill long, straight, subcylindrical, in form of an elongated cone, pointed, trenchant. Nostrils slit longitudinally in the horny substance of the bill, placed near the base. Eyes surrounded with a naked space, which does not communicate with the bill; the face, the space round the eyes, or a part of the neck often naked. Tarsi long; three toes forward, united by a membrane up to the first joint, the posterior toe articulated on the same level with the others; nails short, depressed, without dentilations. Wings moderate; the first quill shorter than the second, which is rather shorter than the third, fourth, and fifth, which are the longest.

M. Temminck observes that the storks live in marshes, and feed principally on reptiles, frogs and their spawn, as well as fishes, small mammiferous animals, and young birds. They are, in all the countries of the world where they occur, a privileged race, on account of their utility and of the havoc they make among noxious animals. Their migra-

White Stork (*Ciconia alba*).

tion takes place in great flocks. They are easily tamed. The moult is autumnal. The sexes do not differ. All the species make a clattering noise with their bills.

The species best known are the White Stork, *Ciconia alba*, and the Black Stork, *Ciconia nigra*.

The White or Common Stork is the *Πελαργός* of Aristotle and the Greeks; *Ciconia* of the Romans; *Cicogna*, *Cicogna bianca*, and *Zigognia* of the Italians; *Cicogne* and *Cigogne blanche* of the French; and *Weisser Storch* of the Germans.

Assured by the kindness with which it is treated in requital for its services in clearing the land of dead as well as living nuisances, the white stork approaches the dwellings of man without fear. In Holland and Germany, especially, the bird is treated as a welcome guest, and there, as indeed elsewhere, it annually returns to the nest which has cradled many generations, on the steeple, on the turret, on the false chimney that the Hollander has erected for its site, in the box, or on the platform which the German has placed for its use. The stump of a decayed tree is sometimes chosen by the bird, and the nest is made of sticks and twigs, on which are laid from three to five cream-coloured or yellowish white eggs, about the size of those of a goose. The incubation continues for a month, at the expiration of which period the young are hatched and carefully attended to by the parents until they are fully feathered and able to procure food for themselves. In the continental towns domesticated storks which have been taken from the nest when young may be often seen parading about the markets, where they are kept as scavengers to clear the place of the entrails of fish and other offal, which they do to the satisfaction of their employers.

Geographical Distribution.—The arrival of the stork in Europe takes place in the spring. In Seville it is very common; but, according to the prince of Musignano, it is very rare and only an accidental visitor near Rome. Though so common in Holland, it very rarely arrives in Britain; nevertheless it regularly visits Sweden and the north of Russia, and breeds there. The winter is passed by the bird in the more genial climates of Asia, and in the northern part of Africa, Egypt especially. Those who have seen these birds in the act of migration speak of their numbers as very large; Belon also remarks, that the storks are never seen in flocks, except when they are in the air; and he relates how, being at Abydos, in the month of August, a great flight of storks came from the north, and when they reached the commencement of the Mediterranean Sea they there made many circuitous turns, and then dispersed into smaller companies. When Dr. Shaw was journeying over Mount Carmel, he saw the annual migration of those which had quitted Egypt; and he states that each of the flocks was half a mile in breadth, and occupied three hours in passing over.

We may now glance at those foreign species of great size and uncouth aspect, termed *Marabous*, *Adjutants*, *Adjutant-cranes*, or *Gigantic Storks*, *Les Cigognes à Col Nud*, and from under whose tail the light and valuable plumes called *Marabou feathers* are procured. We have already alluded to these birds, so remarkable for stature, the enormous volume of their long beak, the nakedness of the head and neck, and the inflatable pendent sac hanging over the upper parts of the chest.

Of these birds three species are known, one from Africa (*Ciconia marabou*, Vigors), one from India (*Ciconia argala*, Vigors), and one from Java and the adjacent islands, described by Dr. Horsfield in the

thirteenth volume of the 'Linnæan Transactions,' and afterwards by Temminck (*Planches colorées*). Temminck, however, committed an error in calling the African bird *Argala*, and the Indian bird by the Senegal name of *Marabou*, having been induced, we believe, to make this transfer in consequence of the superiority of the plumes derived from the Indian species. The consequence of this perversion of native names has been such as might have been expected. Thus, in the last edition of his 'Règne Animal,' M. Cuvier quotes the *Ciconia marabou* of Temminck, with the characters of the Indian bird, as a native of Senegal; while he states the *Ciconia argala* of the same author, to which he attributes the characters of the African species, to be brought from India. Nothing could more strongly evince the necessity of restoring the name of *Argala* to the Indian species, and that of *Marabou* to the African species. For an account of the habits of these birds, see ADJUTANT.

CRANES.

We now come to a group which feed much more on vegetable matters than do any of those which we have previously noticed: there is therefore, as might be expected, a conformable change in the structure of the bill and stomach. The Cranes constitute the family *Gruidæ* of Mr. Vigors, and are divided into several genera.

Genus *Grus*, Pallas. *Generic Character*.—Bill of the length of the head or rather longer, strong, straight, compressed, the point in the form of an elongated cone, obtuse towards the end; lateral base of the mandible deeply channelled; base of the bill elevated. Nostrils in the middle of the bill pierced through and through in the groove, and closed backwards by a membrane. Region of the eyes and base of the bill often naked, or covered with warty excrescences (mamelons). Feet long and strong, a large naked space above the knee; three anterior toes, the middle one united to the external by a rudiment of a membrane; interior toe divided, posterior toe articulated higher on the tarsus. Wings moderate; first quill shorter than the second, which last is nearly as long as the third, and that is the longest; secondaries nearest to the body arched, or very long and subulate in some foreign species.

In the greater part of the species the trachea of the male forms circumvolutions upon itself; in the other species similar sinuosities occur in both sexes, which do not differ in external appearance. Moults once in the year.

Example, *Grus cinerea*.

This is the *Γερανός* (Geranus) of the Greeks; *Grus* of the Romans; *Grue* and *Grua* of the Italians; *Grue* of the French; *Grulla* of the Spaniards; *Graniich* and *Aschgrauer Graniich* of the Germans; and *Crane* and *Common Crane* of the British.

The Crane is migratory and gregarious. Mr. Selby has remarked that in its contour and gait it bears a considerable resemblance to some of the *Struthionidæ*, and that we are reminded of the ostrich by the long flowing plumes that overhang the tail. He is of opinion that through this and other families its affinity to the rasorial birds is readily traced; and he observes that in its internal conformation it differs very essentially from the more typical families of the *Grallatores*, and that its strong and muscular stomach indicates a different general economy from

that of the *Ardeidæ*. This is quite true; but whilst the Crane frequents open and cultivated lands, for the sake of the newly sown corn and seeds to be found in such tracts, it is far from averse to small

Common Crane (*Grus cinerea*.)

testaceous molluscs, worms, frogs, and other reptiles. Temminck says that the nest is placed among the rushes, &c., and sometimes on the walls of isolated houses. The pale bluish-green eggs, marked with brown, are two in number.

Geographical Distribution.—Temminck states that this crane inhabits the marshy plains of the oriental countries; that it is common in the north, migrates regularly in spring and autumn, is rare in its passage in Holland, and only in very severe winters. Asia is one of the tracts of country much frequented by it. Dr. Von Siebold notices it in his list of birds killed at Japan. Mr. Selby states that its equatorial migrations extend to India, Egypt, and other warm parts of Asia and Africa, but that it retires in summer to the northern and eastern parts of Europe to breed. The migrations are performed high in the air, and the progress of the flock may be traced by the loud cries of the birds when they are beyond the reach of sight. The night-time is frequently chosen for these changes of locality. The prince of Musignano notes it as very rare and accidental near Rome; Willughby, however, saw many of them in the poulterers' shops in winter. But it is in England that the alteration of the country, by drainage and inclosure, has caused perhaps the most remarkable absence of these fine birds. They were numerous in the time of our ancestors, and highly esteemed by them, both as objects of sport and as furnishing a dish fit for the table of princes.

Description.—General plumage ashy-gray; throat, front of the neck, and occiput very deep blackish-gray. Forehead and space between the eye and the bill furnished with black hairs; top of the head naked and red. Some of the secondaries arched, longer, and loose-barbed. Bill greenish-black, horn-coloured towards the point, and reddish at the base; iris red-

brown. Feet black. Length from the bill to the end of the tail, three feet eight or ten inches. The old birds have a large whitish space behind the eyes and along the lateral part of the upper portion of the neck.

Genus *Anthropoides*, Vieillot. In this genus are included the beautiful Demoiselle Cranes so conspicuous for the elegance of their actions.

The Demoiselle (*Anthropoides virgo*, *Ardea virgo* of Linnaeus) is about three feet six inches high, measured to the top of the head: from the point of the bill to the tip of the tail it is about three feet in length. Upper part of the head light gray; sides of the head, neck, and depending breast feathers, blackish; head and neck fully feathered. A tuft of pure white loose-barbed feathers, three or four inches long, directed backwards with a curvature downwards behind each eye. General tint slaty-gray; outer portions of all the quill-feathers dingy black. Secondaries longer than the primaries, forming, when the wings are folded, dependent downward-curved plumes. Bill yellowish or flesh-coloured; iris reddish-brown.

The Stanley Crane (*Anthropoides Stanleyanus*, *Anthropoides paradiseus* of Bechstein) is in its general plumage bluish-gray; the top of the tumid head, which is well covered with soft feathers, is whitish, and there is a brownish postocular band; the irides are chestnut-black, and the points of the quills, tail, &c., are brownish-black. Length from the tip of the bill to the end of the tail, three feet six inches.

Locality.—East Indies.

Genus *Balearica*, Gray. Allied to *Anthropoides*, but differing in the oval form of the nostrils, and in having on the top of the head an erect spreading crest, consisting of setaceous feathers. Two species are known: 1, the Balearic Crowned Crane (*Balearica pavonina*), a native of Northern Africa; and 2, the Kaffir Crowned Crane (*Balearica Regulorum*), from South Africa. This latter is the *Grus regulorum* of Lichtenstein, and differs from the former in the far larger size of the wattle. With respect to the habits of these birds, they are presumed to be migratory; but little is known of them, except in captivity, to which the birds are easily reconciled, living in friendship with the domestic poultry, and other captives, and even, as we have heard, interfering to prevent disputes. In a state of nature they are said to frequent swampy places, and to subsist partly upon fishes, worms, and insects, and partly on vegetable substances. They run with the wings expanded, and with great rapidity. Their note is loud, trumpet-like, and hoarse. In the catalogue of the African Museum (which was sold off in 1838) one of the species, there called the Kaffir Crane, is said to be held sacred by the Kaffirs bordering upon the Cape Colony; and if one should happen to be killed, even by accident, a calf or a young cow must be slaughtered as an atonement. Mr. Swainson notices specimens of *Ardea pavonina*, Linn., as having been brought to him when in Malta, from the little island of Lampedosa, where, he says, they are by no means scarce.

To the *Gruidee* are referrible the genera *Psophia* [AGAMI], and *Dicholophus* [CARIAMA], and perhaps *Palamedea*.

HEROPHILUS, a native of Chalcédon, was one

of the most celebrated physicians of the Alexandrine school, and lived in the reign of the first Ptolemæus of Egypt. Of his works, which appear to have been very voluminous, nothing now remains except the extracts made from them by Galen and Cælius Aurelianus, in which they are so interwoven with those of his contemporary Erasistratus, that it is impossible to say what part of the progress which medicine made in their time was owing to the labours of each.

The chief feature which marks the time of Herophilus in the history of medicine is the commencement of the study of anatomy from dissections of the human body, for which purpose the bodies of all malefactors were appropriated by the government. With such zeal did Herophilus pursue this science, that he is said to have dissected 700 subjects, and it was against him and Erasistratus that the very improbable charge was first made of having frequently opened living criminals that they might discover the secret springs of life. (Celsus, 'Præfat.')

By the labours of Herophilus and Erasistratus nearly every part of the anatomy of the human body was rendered clearer, and many most important discoveries were made.

Herophilus practised surgery as well as medicine, but it is probable that very soon after his time the division of surgery and medicine into distinct professions took place. Of his knowledge of medical practice there is not sufficient evidence in the extracts which Galen makes from his works to enable us to form an accurate idea, and his fame must rest rather on the indirect assistance which he afforded by his anatomical researches, than on any immediate addition to the means of curing disease. He does not appear to have drawn many pathological conclusions from his knowledge of the healthy structure; but his observations on the pulse, of which his master Praxagoras had taught him some of the value as a means of discriminating diseases, were important and interesting; and it was he who first showed that paralysis is the result, not of a vitiated state of the humours, as was previously imagined, but of an affection of the nervous system. Herophilus seems to have founded a school which took its name from him. According to Strabo (xii. p. 580) there was a great school (*διδασκαλίον*) of Herophilists in his time established in a temple between Laodiceia and Carura in Phrygia.

HERPES. The word herpes was employed in a very vague sense, and applied to many eruptions of different kinds, until restricted by Willan to a well-defined affection of the skin, characterized by the eruption of clusters of transparent globular vesicles, situated on a red and inflamed base extending some lines beyond them. The vesicles of each cluster commonly vary in size from a millet-seed to a very small pea; the clusters themselves are distinct, being separated by portions of perfectly healthy skin, and they generally rise in quick succession.

The eruption is preceded and accompanied by a degree of constitutional disturbance which generally varies with the extent of the local affection; being often slight and attracting no notice when this is limited and consists of a few clusters only, but very great, and marked by a very high degree of fever, when the clusters are numerous and spread over

an extensive surface in a young and plethoric subject.

The clusters of vesicles, though they retain in all cases the same characters, and follow nearly the same march, are sometimes confined to a particular locality, justifying the designation, *H. labialis*, *H. præputialis*, or assume a particular arrangement, giving rise to the varieties, *Herpes zoster*, when they are situated on one half of the body and extend in a line or band; *H. phlyctenodes*, when they are disseminated; and *H. circinnatus*, when they occur in circles or rings.

In *H. labialis* the clusters are disposed irregularly about the mouth, generally on the external surface of the lips. It is always a slight affection in itself, requiring no treatment beyond that of the disorder which it accompanies. *Herpes præputialis* soon heals under the influence of cleanliness, the local application of the lead lotion, and the administration of a few alteratives. In *Herpes zoster*, familiarly known by the name of Shingles, there is a succession of clusters of white silvery vesicles, forming an oblique line or band, limited to one half of the body, and almost always occurring on the trunk. It is unattended with danger, excepting in old persons, where the clusters are occasionally followed by gangrenous and sloughy sores. In young and plethoric subjects the treatment should consist of bleeding, saline purgatives, diet, and the application to the part of a sedative lotion. In *Herpes phlyctenodes* the clusters are disseminated, and have no particular seat. It is often met with in children during dentition. In *Herpes circinnatus*, or Herpetie Ringworm, the eruption is limited in extent, frequently of a circular form, and consists of extremely minute vesicles, which dry up and terminate in exfoliation, leaving a scurfy areola. It disappears under the influence of the local application of almost any astringent solution.

HERPESTES (Gr. ἑρπεσ, 'to creep'), a genus of carnivorine animals, of the weasel kind, of the family *Mustellidæ*.

HERPETOLOGY, that branch of science which treats of the organization, natural history, and arrangement of reptiles. The term, literally construed, means a discourse upon reptiles, from ἑρπετός (Herpeton) 'a reptile,' and Λόγος (Logos) 'a discourse.' [REPTILES.]

HERPETON (Gr. a reptile), a genus of Water-snakes, of the family *Hydrophidæ*, in which the crown is covered with plates, and the head furnished with two scaly tentacula.

HERRE'RA, ANTONIO, Coronista mayor de las Indias y Castilla, born at Cuellar, 1549, died at Madrid, 19th March, 1625. His great work bears the title of 'Historia General de los Hechos de los Castellanos en las Islas y Tierra Firma del Mar Oceano, en 8 decadas,' 4 vols. folio, Madrid, 1601. A highly improved edition, with corrections and additions, is entitled, 'Descripción de las Indias Occidentales,' 4 vols. folio, Madrid, 1730. The rarest perhaps of several other politico-historical works of Herrera is entitled 'Historiade lo Sucedido en Escocia y Inglaterra en 44 anos que vivió Maria Estuarda,' 8vo., Madrid, 1589, and 8vo., Lisbon, 1590.

HERRERA, FERNANDO, a native of Seville, lived in the sixteenth century, the golden age of Spanish poetry, among the reformers of which he

was prominent. He won the admiration of his contemporaries, who prefixed to his name the epithet of Divine.

An edition, now rare, of his poetical works appeared after his death under the title 'Obras en Verso de Hernando de Herrera,' Sevilla, 1582, 4to. Another equally rare is, 'Versos de Hernando de Herrera, emendados y divididos por él en 3 libros,' Sevilla, 1619, 4to.

Of his prose writings those remaining are, 'Relacion de la Guerra de Chipre, y Suceso de la Batalla de Lepanto,' Sevilla, 1572, 8vo.; and 'Vida y Muerte de Thomas Moro' (translated from the Latin of Stapleton), Sevilla, 1592, 8vo., and Madrid, 1625, 8vo.

HERRE'RA, FRANCISCO DE, surnamed *El Viejo* (the Elder), was born at Seville, 1576. He was one of the most eminent of the Spanish painters of the school of Seville. Among his best works are the Last Judgment in the church of S. Barnard, the Descent from the Cross, and the Effusion of the Holy Ghost, in the church of S. Ines, and, in fresco, the cupola of S. Bonaventura; all at Seville. He also worked in bronze, and has left some etchings. In 1647 he completed his works in the episcopal palace at Seville, and went in 1650 to Madrid, where he died, some say, in the same year, others in 1656.

HERRE'RA, FRANCISCO DE, the Younger (*El Mozo*), painter and architect, son of the preceding, inherited his father's talents. The father being a man of a tyrannical disposition, his son left him, and went to Rome to pursue his studies. After his father's death he returned to Seville and eventually went to Madrid, where he became principal painter to the king, and superintendent of the royal edifices. He died in 1685, aged 63.

HER'RERITE, a mineral found at Albarradon, in Mexico, and so called in honour of Herrera, who first analyzed it. It is discovered in masses of a grass-green colour, and vitreous in lustre. Its constituents are—tellurium, 55.58; carbonic acid, 31.86; peroxide of nickel, 12.32.

HERRICK, ROBERT, was born in the year 1591. Of his life few or no particulars are known, except that he was vicar of a parish called Dean Prior, in Devonshire, for the space of twenty years, was ejected by Cromwell and restored by Charles II., and long held in remembrance by his parishioners as a poet. His poems were published in 1647-48 under the title of 'Hesperides, or the Works, both Human and Divine, of Robert Herrick, Esq.' The 'Hesperides' have been reprinted in 2 vols. 4to., and 2 vols. 8vo.; 'Select Poems,' 1 vol. 8vo.; 'Poetical Works,' 2 vols. 8vo.

HERRIES, RIGHT HON. J. C., an eminent financier and political economist, was born in 1778. He received his education at the University of Leipzig, and in 1798 became a junior clerk in the Treasury. Without family connections or fortune, he had to depend on his own merit and exertions for success. During the administrations of Mr. Vansittart and Mr. Percival, he discharged the duties of private secretary from 1807 to 1811. During the latter year he was made comptroller of army accounts, and soon afterwards was appointed to the office of commissary-in-chief, which, during the war, was a place of great trust and importance. In 1822, after contributing materially to the financial reform of the

civil list, and to a complete alteration in the constitution and practice of the customs and excise departments, Mr. Herries entered political life by accepting the office of secretary of the treasury, when he was soon afterwards elected member for the borough of Harwich, which he continued to represent until 1841. In 1827 he became chancellor of the exchequer under Lord Goderich's administration, and in 1828 he was appointed master of the mint and president of the board of trade. In 1841 Mr. Herries unsuccessfully contested the borough of Ipswich, and remained out of office during the next six years, when he was returned for Stamford. During Lord Derby's administration he held office as president of the India board; but on the termination of his lordship's ministry, the right honourable gentleman finally retired from Parliament, to pass the rest of his days in domestic ease.

Amidst his many active duties, Mr. Herries was not inattentive to literature and the arts, and he was well acquainted with the ancient and modern languages of Europe. In early life he published a translation from the German work of Frederick Gentz, on the state of Europe before and after the French revolution, which excited much attention at the time; and a second edition made its appearance in 1802. His death took place in April, 1855.

HERRING, a fish of the order *Clupeidae*, of which it may be regarded as the type, and of the genus *Clupea*. It is a scaly fish, and its teeth are small and numerous. Herrings are marine fishes, congregating in vast shoals, and periodically visiting certain coasts in great multitudes. They are found in the seas of the northern parts of the world, especially in the temperate regions. They deposit their spawn in shallow water, and are very prolific—the roe of a single female herring having been found to contain 60,000 eggs. They are believed to be inhabitants of deep water, but coming up to the coasts in shoals at regular seasons they swim on the surface, and fall an easy prey to larger fish, and also to gulls and sea-birds. They are usually caught in nets. Fresh-water herrings, so called, are fishes of the genus *Coregonus*, and family *Salmonidae*, and are correctly called gwyniad in Wales, powan in Scotland, and pollan in Ireland. The herring salmon of the North American lakes is of the same nature, and does not belong to the herring tribe.

HERRING FISHERY. The principal season for herring fishing commences in September and ends in December, but to some extent, the fishing is carried on all the year round. Yarmouth, Lowestoft, Hastings, Folkestone, Cardigan Bay, and Swansea in England and Wales; the coasts of Caithness, Sutherland, Aberdeenshire, Banffshire, Morayshire, and Ross-shire in Scotland; and Galway, Killybegs on the coast of Donegal, Mayo, the estuary of the Shannon, the coast between Dingle Bay and Kenmare, Bantry Bay, Waterford, and from Mizen Head to Cahore Point on the Wicklow coast, in Ireland—are the principal localities.

The common mode of taking herrings is by a 'drift' net, being in fact a set of large nets joined together extending nearly a mile in length. They are let into the water in a straight line, with a boat at each end, and both boats and nets are then allowed to drift with the tide. The herrings are caught by

striking against the net, and becoming entangled in its meshes. When brought on shore some are sold fresh, but the greater part are cured by means of salt. At Yarmouth and some other places the herrings are, after being slightly salted, made into what are called 'bloaters,' by a process of smoking.

Herring fisheries have always been the subject of legislative protection in the United Kingdom. An act passed in 1808 granted bounties to the fishermen, and prescribed regulations for fishing, curing, inspecting, and branding herrings. The whole coast of Great Britain was divided into districts, in each of which officers were appointed to inspect and brand the barrels of herrings, and to prevent fraud in regard to the bounty. In 1817 a further boon was granted to the fishermen by allowing them the use of salt duty free, a peculiar advantage which ceased in 1823 by the repeal of the duty on that article. In 1830 the bounty was wholly withdrawn; and the 21st and 22nd Vict., c. 69, exacts a fee for every barrel of herrings on which the government brand is imposed as a mark of its quality, prohibits the use of certain nets and certain methods in taking the fish, and surrenders the traffic to the care of private interest and the salutary effect of public competition.

In addition to the home fisheries, we obtain a large supply of herrings from Norway and Newfoundland. In 1863 the exports of herrings from the United Kingdom amounted to 438,745 barrels, of the value of 501,032*l.* Prussia, Hanover, and Austria were the principal markets.

HERSCHEL, WILLIAM, was the second son of a musician at Hanover, and was born November 15, 1738. His father brought him up to his own profession, with a good education in other respects. At the age of fourteen he was placed, it is said, in the band of the Hanoverian regiment of guards, which regiment he accompanied to England at a period which is variously stated from 1757 to 1759. Another account states that he came to England alone. After his arrival, he was for some time at Durham, where he is said to have superintended the formation of a band for the militia, and afterwards was for several years organist at Halifax, where he employed himself in teaching music and studying languages.

About 1766 he was organist of the Octagon chapel at Bath; in which place he began to turn his attention to astronomy. Though not a mathematician of the first order, his attainments in that science were more than respectable. The earliest writing of Herschel which has come to our knowledge is the answer to the prize question in the *Ladies' Diary* for 1779, namely: 'The length, tension, and weight of a musical string being given, it is required to find how many vibrations it will make in a given time, when a small given weight is fastened to its middle and vibrates with it.'

His astronomical pursuits led him to desire a telescope, and, as the purchase of a good reflector was 'fortunately' above his means, he resolved to make one for himself. After many trials he succeeded in making a Newtonian telescope of five feet focal length.

Herschel began to contribute to the 'Philosophical Transactions' in 1780, and in 1781 announced to the world his discovery of a supposed comet, which soon turned out to be a new planet. [URANUS.]

It is the method which gave rise to it on which this part of Herschel's fame must rest. Perceiving how much depended upon an exact knowledge of telescopic phenomena, and a perfect acquaintance with the effect produced by differences of instrumental construction, he commenced a regular examination of the heavens, taking the stars systematically in series, and using one telescope throughout. Herschel was not a diletante star-gazer, but a volunteer carrying on with no great pecuniary means a laborious and useful train of investigation.

The announcement of this comet or (as it turned out) planet drew Herschel immediately into the full blaze of fame; and George III. honoured his reign by immediately attaching the new astronomer to his court under the title of private astronomer to the king, and with a salary of 400*l.* a year. Herschel fixed his residence first at Datchet, and afterwards at Slough, near Windsor, and his abode became, as Fourier remarks, one of the remarkable spots of the civilized world. His family consisted at first of one of his brothers, and his sister, Miss Caroline Herschel, who was his coadjutor and assistant in his computations and reductions, and was also employed in observation. [HERSCHEL, CAROLINE LUCRETIA.]

Herschel married a widow lady, Mrs. Mary Pitt, and left one son, whose name has long been known to the public as one of the most active and successful adherents of science that our day has produced.

Herschel was soon in affluent circumstances, partly by the profits arising from the sale of his mirrors for reflecting telescopes, and partly by the jointure of his wife, which was considerable, and he died wealthy. In 1816 he was presented with the decoration of the Guelphic order, and in 1820 was chosen the first president of the Astronomical Society. After completing his paper on 145 double stars, which was published in the first volume of the *Transactions of the Astronomical Society*, his health began to decline, and his death took place on August 23, 1822.

Herschel must be remembered by the number of bodies which he added to the solar system, making that number half as large again as he found it. Including Halley's comet, and the four satellites of Jupiter and five of Saturn, the number previously known was eighteen; to which he added nine, namely, Uranus and six satellites, and two satellites to Saturn. His discovery of the rotation of Saturn's ring, his measurements of the rotation of Saturn and Venus, his observations of the belts of the former, and his conjectural theory, derived from observation, of the rotation of Jupiter's satellites, with a large number of minor observations, prove that no one individual ever added so much to the facts on which our knowledge of the solar system is grounded. To this we must add, that his announcement (in 1803) of the motions of binary stars round each other was accompanied by the first proof that there exists in the universe organized systems besides our own; while his writings on the Milky Way, the constitution of nebulae, &c., &c., gave an experimental foundation to the conception that what was called the universe might be, and in all probability is, but a detached and minute portion of that interminable series of similar formations which ought to bear the name.

The instrument by which this great work was

achieved was the reflecting telescope. The second reflecting surface which is found in the constructions of Newton, Gregory, and Cassegrain, having been rejected, and the eye-piece applied directly to the image produced from the large mirror, forms the distinguishing feature of the Herschelian telescope. Herschel had constructed more than one such instrument of 20 feet focal length before he attempted the enormous one of 40 feet. This instrument was begun in 1785, and Herschel dates the completion from August 28, 1789, on which day he discovered with it the sixth satellite of Saturn.

The catalogues of double stars, nebulae, &c., and of the comparative brightness of stars, would alone constitute a title to the name of a distinguished astronomer, and the optical researches, with those on the refrangibility of heat, are highly valuable: while the papers on the power of telescopes should be read by all who wish to understand those instruments.

HERSCHEL, CAROLINE LUCRETIA, sister to the great astronomer of that name, and the sole assistant of his astronomical researches, was born in Hanover in 1750. So highly were her scientific labours in connection with her brother's abstruse calculations appreciated by his Majesty, George III., that he was graciously pleased to grant her a salary sufficient for her moderate requirements. Not only did she execute the whole of the extensive and laborious numerical calculations necessary to render her brother's researches available to science, but she found time at intervals, both for actual astronomical observations of her own, and for the execution of more than one work of great utility and extent. With a Newtonian sweeper, constructed by her brother, she was in the habit of searching the heavens for comets, and that so effectively as to be rewarded with eight different discoveries from August 1786 to August 1797. Her claim to the first discovery of five of them was admitted by the scientific world. During these sweeps of the heavens, Miss Herschel also discovered several remarkable nebulae and clusters of stars which had never before been observed, and which are recorded in Sir William Herschel's catalogue. Among her astronomical works, which she found time to execute at intervals of leisure, were—1st, 'A Catalogue of 561 Stars observed by Flamsteed;' 2nd, 'A General Index of Reference to every Observation of every Star inserted in the British Catalogue;' 3rd, 'A Zone Catalogue,' comprehending all the nebulae and clusters of stars observed by her brother in his sweeps; for which she received the gold medal of the Astronomical Society of London, and was elected an honorary member. On the death of her brother, in 1822, she left England, where she had resided for about half a century, and returned to her native place, which she never again quitted—passing the last twenty years of her life in repose, and respected by all who knew her. She died in 1848, in her ninety-eighth year.

HERSCHELITE, a mineral which occurs in six-sided prisms, and so called in honour of Sir William Herschel. In colour it is translucent, white, or opaque. It consists of potash, silica, and alumina; and its specific gravity is 2.11.

HERSE (Fr. *herise*), in the Middle Age, a kind of machine used in fortification, which consisted of

a series of spikes projecting from transverse pieces of wood. It was sometimes used as a portcullis, to serve as an interior protection, after the outer gate had been forced by the enemy.

HERSFELD. [HESSE-CASSEL.]

HERTFORD. [HERTFORDSHIRE.]

HERTFORDSHIRE, an English county, situated between $51^{\circ} 36'$ and $52^{\circ} 5' N.$ lat., and $0^{\circ} 13' E.$ and $0^{\circ} 45' W.$ long. It is bounded N. by Cambridgeshire, E. by Essex, S. by Middlesex, W. by Buckinghamshire, and N.W. by Bedfordshire. Its length from N.E. to S.W. is 39 miles; its greatest breadth, N.W. to S.E., 25 or 26 miles. Its area is 391,141 statute acres, of which about 350,000 are grass and arable. The population at the census of 1861 numbered 173,280—84,352 males, and 88,928 females—being an increase of 5982, or 4 per cent., from 1851. The number of inhabited houses in the county was 34,893; 1563 being returned as uninhabited, and 193 building.

Surface, Rivers, &c.—Hertfordshire has no lofty hills. The highest elevations are the Chalk Downs. Kensworth Hill, just within the border of the county, near Dunstable, is 908 feet high. The surface of the county is generally undulating, and from the abundance of wood presents a variety of pleasing scenery.

The rivers for the most part belong to the basin of the Thames. The principal are the Colne and the Lea: the Hiz and some other streams in the northern part of the county belong to the system of the Ouse. The Lea rises in Luigraue or Leagrave Marsh, near Luton, in Bedfordshire. Its whole length, from the source to its junction with the Thames at Bromley, near London, is about 50 miles. The navigation commences at Hertford.

The Colne, a feeder of the Thames, rises between Idlestree, or Elstree, and Barnet, and flows through a projecting part of the county of Middlesex into Hertfordshire again, which it leaves at Rickmansworth. The streams which belong to the system of the Ouse have but a small part of their course in this county.

The New River, which was begun in 1608, and which contributes so largely to the water supply of the metropolis, is brought to London from springs in the neighbourhood of Ware. It has a feeder from the Lea near the town, and is carried along the valley and nearly parallel to the course of that stream.

The county is traversed by the London and North-Western, the Great Northern, and Great Eastern lines, and by the Grand Junction Canal.

Geology, Climate, and Agriculture.—This county is comprehended in the chalk basin of London. The S.E. and S.W. parts are occupied by the London clay, which extends to a line drawn from the Stort, between Sawbridgeworth and Bishop's Stortford, to the north of Ware, Hertford, and Hatfield, to St. Albans, and from thence along the valley of the Colne. To the N.W. of this line all the county is occupied by the chalk, excepting a few spots along the border of Bedfordshire, where the subjacent strata crop out.

The county has no minerals of any value: there are a few medicinal springs, chiefly chalybeate; the principal are on Barnet Common, Northaw Common,

and at Cuffley, in Northaw parish, all near the Middlesex border.

The climate is as mild and genial as that of most of the inland counties. The harvest is early where the soil is light and rich, as is the case in some of the valleys. On the cold wet clays which are found in some parts of the county, and the most exposed tops of the chalky hills, the crops are later; wheat, barley, oats, turnips, and sainfoin being the chief products.

The number of resident gentry in Hertfordshire tends to introduce a high state of cultivation around their immediate residences; but as the mansions are generally erected in the driest and best situations, the cold wet clays are somewhat neglected.

Hertfordshire is remarkable for its high banks and hedges. Wherever the old high banks have been levelled, and neat quick hedges have been planted in their stead, the ground which has been gained has soon paid the expense.

It cannot be said that there is any peculiar system of cultivation in Hertfordshire. Every system may be occasionally met with. The consequence has been a great difference in the products of adjoining farms. The crops are reaped as close to the ground as possible, in order that the straw may be sold in London, and manure brought back in return. Fewer cattle are fed in winter than in more distant counties, as manure can be obtained without them.

Garden husbandry has been introduced on the best soils nearest to London for the growth of early potatoes, cabbages, peas, and other culinary vegetables, which are succeeded in the same year by other crops, the whole being forced by an abundance of manure.

There are many orchards in Hertfordshire, chiefly for apples and cherries, which are sold in London. No cider is made. There are many woods and coppices in the poorer soils, but they are fast diminishing in number.

The manufactures in Hertford are chiefly confined to paper and straw-plait, but much malting is carried on.

Divisions and Towns.—Hertfordshire is divided into 8 hundreds and 134 parishes. It is in the diocese of Rochester and the Home circuit. The assizes are held at Hertford. The county returns three members to Parliament; and the borough of Hertford two, making five in all.

Two members were formerly returned for St. Albans, but that borough was disfranchised for bribery in 1852.

The number of registered electors for the county in 1865 was 6228.

The following are the principal towns, with the population of each in 1861:—

St. Albans. [ALBANS, ST.]

Baldock is 34 miles from London. The town is said to have been built by the knights templar before the time of Henry III. The church is a large and handsome Gothic edifice. There is a range of six almshouses in the High Street. A considerable trade is carried on in malt, and there are also manufactures of straw-plait. Population, 1974.

Barnet is about 13 miles N.W. from Hertford, and 11 miles from London. It formerly belonged to the abbot of St. Albans, to whom the market was

granted in the reign of Henry II. The country around is celebrated for its hay, and a great deal of business is done at the market. The church was erected in 1400, by John Mort, bishop of St. Albans. It contains many ancient monuments. In 1471 the decisive battle of Barnet was fought on Gladsmore Heath, near the town, between the York and Lancastrian forces, when the latter were defeated, and their leader, the earl of Warwick, was killed. An obelisk has been erected in commemoration of this event. Population, 2989.

Berkhamstead is 26 miles from London (or 28 by the North-Western Railway), and about 18 from Hertford. It has a considerable trade, which is assisted by the navigation of the Grand Junction Canal. The town is large and handsome. It was called by the Romans *Durobrivæ*, and became a place of some eminence under the Saxons. The church is a Gothic structure of considerable beauty, containing numerous interesting monuments. Among the schools in the town is a free grammar-school, founded in the reign of Henry VIII. There is also a corn exchange, and a gaol and house of correction. Cowper, the poet, was born here in 1731, while his father was rector of the parish. Population, 3585.

Bishop's Stortford is distant from London 30 miles (or 32½ by the Great Eastern Railway). It takes its name from the river Stort and the fact that the manor belonged from a very early period to the bishops of London. The town is built in the form of a cross, the two principal streets intersecting each other, with the market place in the centre. A great deal of corn is accumulated here, and the malting trade carried on to a great extent. The general business of the town is much facilitated by a canal communicating with the Lea. The church possesses a fine lofty tower. There is also a town-house and several chapels. Population, 5390.

Broxbourne, a place on the Great Eastern Railway, 19 miles from London, resorted to chiefly for the purpose of fishing. It contains a church dedicated to St. Austin. Population, 2663.

Cheshunt, a village 14 miles from London by the Great Eastern Railway, and about 6 S.E. from Hertford. The name is written in Domesday 'Cestrehunt,' from which it has been conjectured that it was a Roman station. Cheshunt was the retreat of Richard, son of Oliver Cromwell, under a feigned name, and the scene of his death in the reign of Queen Anne. Population of the parish, 6592.

Hatfield is 19½ miles from London, and about 6½ W.S.W. from Hertford. The manor of Hetfelle (as it is called in Domesday) was granted by King Edgar to the abbey or monastery of St. Ethelred at Ely, and upon the erection of that abbey into a bishopric in 1108, is supposed to have acquired the designation of Bishop's Hatfield. The bishops of Ely had a palace at Hatfield, which, with the manor, was made over to the crown in the time of Henry VIII.: the palace was the residence of Prince Edward, afterwards Edward VI. Elizabeth held her first privy council here. The gateway and west end of the palace are still standing. Hatfield is a station on the Great Northern Railway, the head of a poor-law union, and a county polling-place. Population of the parish, 3871.

Hemel Hempstead is 23 miles from London, and

about 15 W.S.W. from Hertford. The town consists chiefly of one long street. The females of the town are much engaged in making the straw-plait, and there are corn and paper mills in the neighbourhood. The town-hall is a long narrow building, with an open space under for the market, which is one of the largest in the county for corn. The town contains also a union workhouse, and the West Herts Infirmary. The church, a large building, is partly of Norman architecture, of which the west door is a fine specimen. Population, 7948.

Hertford, the county town, is in a low valley below the junction of the Maran or Mimram, and just above that of the Beane with the Lea, which last-mentioned river runs through the town. It is 26 miles from London by the Hertford branch of the Great Eastern Railway.

The town is irregularly laid out, but the streets are well paved, and the town has a very clean and neat appearance. It has two parish churches. Near the east end is a large building belonging to the governors of Christ's Hospital, in London, at which a number of the girls and of the younger boys of that charity receive their education. The buildings are capable of containing 500 children, with their needful attendants. Haileybury College, formerly used for the instruction of students intended for the civil service of the late East India Company, is at a short distance from the town.

No manufacture is carried on at Hertford, but a good deal of business is done in malting, and there are many corn-mills on the Lea, the Mimram, and the Beane. It also has a large corn market. It is a municipal borough, and is governed by four aldermen and twelve councillors. The assizes for the county are held here. Hertford returns two members to Parliament. Population of the municipal and parliamentary borough, 6769. The number of voters on the parliamentary register for the borough in 1864 was 539. Hertford is also the place for the county election.

Hertford is a place of considerable antiquity. About 905, Edward the Elder built the castle, and rebuilt the town, which had probably been ruined by the Danes. Jean II., king of France, and David, king of Scotland, spent part of their captivity here during the reign of Edward III. Queen Elizabeth occasionally resided and held her court in the castle. There are numerous almshouses and other charities, an infirmary, county-hall, new corn exchange, free library, gaol, national, grammar, and charity schools in the town.

Hitchin is 34 miles from London, and 14½ N.W. from Hertford. The town, which consists of several streets, is irregularly laid out. The principal trade is in corn and malt. Much straw-plait is made; there are some breweries, and also a silk-mill. The church is a handsome edifice, built upon the foundations of a more ancient structure. The south porch is a remarkably fine specimen of Gothic architecture in the perpendicular style, and there is a font of the same character; also numerous sepulchral monuments and brasses. There are several public schools. Hitchin is a station on the Great Northern Railway, and has several lavender farms. Population, 7677.

Hoddesdon is a hamlet 17 miles from London. The town consists chiefly of two long streets. The

ancient market-house, a wooden edifice supported on arches and pillars curiously carved, is in the middle of the town. The chief business of the town is malting. The church is large, of perpendicular character, with some elegant chapels and ancient monuments. Population, 1898.

Rickmansworth is 18 miles from London, and about 27 from Hertford. The town is irregularly laid out. The church, with the exception of the tower, was rebuilt some years ago. There are several silk, paper, and flour mills near the town; and some straw-plaiting and horse-hair weaving is carried on. The Grand Junction Canal passes through the town. Near Rickmansworth is Moor Park, which was the residence of Cardinal Wolsey, of the unfortunate James, duke of Monmouth, and of Lord Anson. The town contains several free schools. Population, 4873.

Royston is 37½ miles from London, and about 17 from Hertford. It is situated partly in Cambridgeshire. The principal business is malting; a large corn trade is also carried on. The church was formerly the conventual church of a priory of the regular canons of St. Augustine. A brick building in the northern part of the town was once the occasional residence of James I. There are schools of various descriptions in the town, a union workhouse, and a market-house, under which a curious ancient cave has been discovered. Population, 1882.

Tring is 31½ miles from London by the North-Western Railway, and about 23 miles from Hertford. The town is neat, and contains several good houses. The church is an ancient building, with a massive tower, and contains some ancient monuments. There is a Lancasterian free school, and various small charities in the town. Manufactures of silk, canvas, and straw-plait are carried on. The parish is intersected by the Grand Junction Canal. Near Tring the largest cutting on the North-Western Railway occurs, passing through chalk strata. It extends nearly two miles and a half, has an average depth of forty feet, but in some places amounting to sixty; and 1,400,000 cubic yards of chalk were removed in forming it. Population, 4841.

Ware is 20 miles from London, and 2½ miles from Hertford by the Enfield branch of the Great Eastern Railway. Up to this place the Danes, in the reign of Alfred, brought their vessels, and protected them by a dam or weir across the river, from which weir the town is said to have obtained its name; the Lea is navigable to Ware. The church consists of a chancel, with a chapel on each side; a nave with two side aisles, and two projections resembling transepts; with a square embattled tower. There is considerable trade at Ware in grain and coal. The town is also one of the chief seats of the malting trade in the kingdom. At one of the inns is a large bedstead, 12 feet square, elaborately carved in oak, and of uncertain origin and use. It is alluded to by Shakspeare ('Twelfth Night,' act iii., scene ii.), and is popularly known as the Bed of Ware. There are numerous schools in the parish. Near Ware are the head-springs of the New River, by which water is conveyed for the supply of the northern part of London. Population, 5397.

Watford is 15 miles from London by the North-Western Railway. It is situate close to a ford over

the Colne (whence its name), and has manufactures of straw-plait and malting. The place is also a large mart for corn and live stock. The Grand Junction Canal runs on its western side. The town consists principally of one main street, about a mile in length, near the centre of which stands the church. Population, 7418.

History and Antiquities.—At the time of Cæsar's invasion, Hertfordshire seems to have belonged to the Catyenchlani, or Catuellani, of whom Cassivellaunus, the antagonist of Cæsar (B.C. 54), is supposed to have been the chief. [BRITANNIA.]

Several of the ancient British roads or trackways crossed this county. The traces of the British Watling Street are obliterated by the Roman road afterwards carried along the same line. Traces of Ermin Street, and still more of Icknield Street, may yet be recognized. The Romans included Hertfordshire in the province of Flavia Cæsariensis. At Wilbury Hill, three miles west of Baldock, is an ancient camp on the Icknield Way, inclosing about seven acres.

When the Saxons subjugated Britain, Hertfordshire appears to have been included in the two kingdoms of Essex and Mercia. In the invasions of the Northmen, which troubled the close of the reign of Alfred (in 896), they brought their vessels up the Lea to the neighbourhood of Hertford or Ware. Edward the Elder, son of Alfred, built Hertford Castle.

In the civil broils of the reign of John, Hertford Castle was defended for the king by Walter de Godarvil, against the revolted barons and the Dauphin Louis of France. After the general rising of the peasantry under Wat Tyler and Jack Straw, many of the ringleaders were tried and executed at St. Albans. In the war of the Roses, this county was repeatedly the scene of contest. The battle of Barnet, in which Warwick fell in battle against Edward IV., was fought in Middlesex, just beyond the boundary of Hertfordshire.

On the breaking out of the war between Charles I. and the Parliament, this county was the scene of one of Cromwell's earliest exploits. While yet a captain of a troop of horse which he had raised, he arrested the high-sheriff of Hertfordshire as he was proceeding to St. Albans to publish the king's proclamation declaring all the parliamentary commanders traitors.

HERTHA, or HERTHUS, the Goddess of Earth among the ancient Germans. Tacitus ('Mor. German.,' c. 40) says that she was worshipped by the Suevi, and that her sanctuary was in a grove in an island of the ocean, and was served by a single priest. A cart, covered by a cloth to conceal the goddess, was taken out of the sanctuary on certain occasions, and was drawn by cows about the country with great solemnity. This was a time of general rejoicing, a cessation of war took place, and peace reigned over the land, until the goddess was restored to her sanctuary.

HERVEY, JAMES, born in 1714, was educated at Lincoln College, Oxford. He took orders in the established church, devoted his whole life to acts of piety and beneficence, and died early, of a decline, in 1758. For some years preceding he had been rector of Weston-Favell in Northamptonshire. His

works are numerous, and all religious. In doctrine he leaned towards the Calvinistic school. The most popular of his works were, 'Meditations among the Tombs,' 'Contemplations in a Flower Garden,' 'On the Night,' &c., 1746-47; and 'Theron and Aspasia; or, a series of Dialogues and Letters on the most important Subjects,' 1753.

HERZEGOVINA, an extensive tract of country situated on the eastern shores of the Adriatic, generally known as Turkish Dalmatia, has of late years assumed some geographical importance from the successful resistance of the Montenegrins to Turkish domination, of which Herzegovina formed the centre and starting point. It lies between lat. 43° and 44° 20' N. The southern and larger portion belongs to Turkey, and the remainder to Austria. It is bounded N.E. by Croatia and Bosnia, S. by Montenegro and Albania, and W. by Dalmatia and Cattaro. Herzegovina formerly belonged to Croatia, when that kingdom was independent; but in 1326 it was incorporated with Bosnia. Under the Emperor Frederick III. it became an independent duchy; but after many protracted contests with the Ottoman arms, it was finally ceded to Turkey by the peace of Carlovicz, in 1697. The Porte once more incorporated it with Bosnia, and it has been retained by that power for the last two centuries. The extent of Bosnia, including Herzegovina, is estimated at 900 square leagues; and, according to a census taken in 1848, the population was roughly estimated at 1,400,000. The Bosniaks form about a third of the population; the Croats are estimated at 180,000; and the Morlachs at 150,000; the latter being concentrated at Herzegovina, and famed as the most determined adversaries of the Turks. All these different peoples belong to the ancient Slavonic race. They chiefly follow the Greek Church, and have a thorough detestation and contempt for the Turkish rule.

HESIOD. [PAS-DE-CALAIS.]

HESIOD was a native of Asera, a village at the foot of Helicon, whither his father had migrated from Cuma in Æolis. The only works that remain under the name of Hesiod are—'The Theogony,' 'The Shield of Hercules,' and the 'Works and Days.' The 'Works and Days' consists of advice given by Hesiod to his brother Perses on subjects relating for the most part to agriculture and the general conduct of life. In its present state the poem shows want of purpose and of unity, too great to be accounted for otherwise than on the supposition of its fragmentary nature. The 'Theogony' consists, as its name expresses, of an account of the origin of the world, including the birth of the gods, and making use of numerous personifications. The 'Shield of Hercules' is a fragment, or rather a cluster of fragments; some of them by very late Rhapsodists, who copied, according to Aristophanes the grammarian, from Homer's description of the shield of Achilles.

The best modern editions of Hesiod are Götting's (in 1 vol. 8vo., published in the 'Bibliotheca Græca'), and Dindorf's, Leipzig, 8vo.

HE'SIONE (Zoology), the name of a genus of *dorsibranchiate Annelids*, with a short but rather stout body, composed of a few ill-defined rings. A very long cirrus, which probably executes the function of branchiae, occupies the upper part of each foot, which has also another lower one and a packet

of fine bristles. The proboscis of Hesione is large, and without either jaws or tentacles.

HESPERIDÆ (Stephens), a family of Lepidopterous insects of the section *Lepidoptera diurna* of Latreille.

Distinguishing Characters.—Antennæ terminated by a distinct club, generally with a minute hook at its extremity; tibiae with two pairs of spurs, one at the apex, and the other near the middle; claws very small, bifid; body thick; wings small, the posterior pair with a groove to receive the abdomen. The larvæ are pubescent, or naked, and have a large head; pupa smooth, inclosed in a web.

These little butterflies have a large head, and a thicker body and smaller wings than the more typical species; they are, moreover, at once distinguished from them by their possessing two pairs of spurs, or spines, to the legs; their flight is short and in frequent jerks; hence they have received the name of Skippers.

One species, *Hesperia sylvana*, very common in various parts of England, and chiefly found on the borders of woods, will afford an example of the tribe of which we are treating.

There are several other species of the family *Hesperiidæ* found in this country, of which the *Thymele alveolus* may be noticed. This is a little black butterfly with numerous silver-like spots, and is known to the English entomologist by the name of the Grizzled Skipper.

HESPERIDES, in Greek mythology, a family of Nymphs, the daughters of Atlas, by Hesperis, the daughter of Hesperus. They dwelt in a beautiful garden in the western parts of the earth, in which grew the celebrated tree which bore golden apples. These apples were guarded by a fierce dragon named Ladon, which never slept. Hercules killed the dragon and carried off the precious fruit. The gardens of the Hesperides are variously placed—in an oasis of the African desert, in Cyrenaica, at the foot of Mount Atlas, and in the Happy Islands of the Atlantic.

HE'SPERIS, a genus of plants belonging to the natural order *Crucifera*, and the tribe *Sisymbrea*. The flowers emit a sweet fragrance during the night, and hence the genus derives its name. *H. matronalis*, Dame's Violet, is the only British species.

HESSE, an extensive country of Germany, which, in ancient times, was inhabited by the Catti. Till about the middle of the thirteenth century the history of Hesse was blended with that of Thüringen; but Henry Raspe, landgrave of Thüringen, dying without children in 1247, a war for the succession took place, which was terminated in 1263 by a compact, by which Hesse was separated from Thüringen, and assigned to Henry, son of Sophia, duchess of Brabant, daughter of the late landgrave's brother, who was the common ancestor of all the succeeding landgraves of Hesse-Cassel, and the dukes of Hesse-Darmstadt.

HESSE-CASSEL, from the time of William IV., 1592, suffered in the successive wars which desolated Germany, but did not sustain any loss of territory; on the contrary, it made several acquisitions. After the Thirty Years' War, Hessian mercenaries in the service of other continental powers were employed in almost all the European and Turkish wars; a system which indeed enriched the princes of Hesse,

but did not tend to promote the prosperity of the country. The title of elector was first assumed by the landgrave William IX. in 1803.

This prince concluded a treaty with the allied powers, and subsequently became a member of the German Confederation. He died in 1821. His son and successor, William II., embroiled himself seriously with his subjects. He appointed his son, the electoral prince, regent, who entered on his functions October 1, 1831, and succeeded to the electorship November 20, 1847.

The electorate of Hesse is situated between 49° 56' and 52° 25' N. lat., and 8° 25' and 10° 8' E. long. It consists of three distinct portions, of which the largest, extending only to 50° 40' lat. and 10° 15' long., is bounded N.E. by Hanover and the Prussian province of Saxony, E. by Weimar and Bavaria, S. by Bavaria, W. by Nassau and Hesse-Darmstadt. The detached portions are the county of Schaumburg on the N., surrounded by Hanover and Lippe, and the lordship of Schmalkalden on the E., surrounded by the Saxon principalities and the Prussian circle of Schleusingen. The area of the whole is 4430 English square miles.

Divisions.—The electorate is divided into four provinces, with a total population of 738,454.

I. LOWER HESSE (358,806 inhabitants), divided into 10 circles, with 34 towns, 8 market boroughs, and 519 villages. Chief town, Cassel, the capital of the electorate. [CASSEL.]

II. UPPER HESSE (119,493 inhabitants), divided into 4 circles, with 16 towns, 4 market boroughs, and 206 villages. Chief town, Marburg, the capital, and seat of the university.

III. FULDA (136,572 inhabitants), 5 towns, 7 market boroughs, and 198 villages. It consists of, 1, the grand-duchy of Fulda; 2, the circle of Hersfeld; 3, the circle of Hünfeld; 4, the lordship of Schmalkalden.

IV. HANAU (123,583 inhabitants), 7 chief towns, 14 market boroughs, 189 villages, divided into circles. Chief town, Hanau, at the confluence of the Kinrig and the Main, with a population of 16,582.

Face of the Country, Soil, Climate, and Productions.—The country is in general hilly; but it contains numerous valleys, which in some places expand into more extensive plains. On the S.E. and S. the Thüringerwald, the Rhön, and the Spessart extend their branches into the country from the Saxon duchies and Bavaria, and cover the province of Hanau, and the whole tract between the Werra and the Fulda. The other principal chains are the Hundsrück, the Wesergebirge, and the Vogelsgebirge. The soil is almost unexceptionally fertile and well adapted for agriculture. The climate is on the whole temperate, and everywhere healthy. The principal rivers are the Main, the Weser, the Werra, the Lahn, and the Fulda.

Corn, maize, pulse, and potatoes in great abundance, are cultivated. Flax and timber are staple articles: tobacco, hemp, madder, a few hops, and rapeseed are also among the products. The vine is cultivated only in some parts of Hanau. The pasturage is in general good. Garden produce of excellent quality is raised about Cassel and Hanau. The breeding of cattle is general. Domestic poultry and game are very abundant. Hesse abounds in mineral

wealth, producing silver, copper, lead, iron, quick-silver, cobalt, salt (from saline springs and in great quantities), saltpetre, vitriol, and alum. There are also coals, marble, very fine white alabaster, porcelain, potter's clay, pipe clay, &c. Gold in small quantities is found in the sands of the Edder.

Manufactures, Trade, &c.—The manufactures of Hesse-Cassel have been greatly extended since the state joined the German Customs Union. The most important are linen fabrics, called Osnaburgs, flannels, carpets, cottons, silks, and velvets; iron and steel goods of every description, paper, wooden wares, pianos, chemical products, tobacco, beet-root sugar, pottery, and jewellery, are also made. The chief exports are linens, carpets, jewellery, iron and steel goods. The imports consist of colonial goods, cotton, silk, wine, and brandy. The chief branch of trade is in the transit of goods, which is facilitated by the navigable rivers and numerous railways. In 1832 Hesse-Cassel and Hesse-Darmstadt united with Prussia to form the origin of the German Customs Union.

Constitution and Government.—The present constitution of Hesse-Cassel was proclaimed January 5, 1831. It was abrogated for some time, a new charter, of April 13, 1852, being substituted; but in consequence of general dissatisfaction, expressed in the refusal to pay taxes, the constitution of 1831 was re-established by a decree of the elector, of June 21, 1862. According to this fundamental law, the executive power alone is in the hands of the sovereign and his responsible ministers, and the right of legislation is vested in a House of Parliament, consisting of a single Chamber. It is composed, in conformity with the electoral law of May 6, 1863, of the princes of the reigning house; the heads of a number of noble families possessing landed estates; nine deputies of other nobles and of noble institutions; two deputies of universities; sixteen representatives of towns, two of which are from the city of Hanau, and two from Cassel; and sixteen representatives of rural districts. The right to vote, as also that of being elected a deputy, is bound to a small property qualification. One half of the representatives of rural districts must be engaged in agriculture; but the towns may choose their deputies from among any class of citizens. The council of ministers is responsible to the people, and may be put in accusation by a vote of the Chamber.

Church and Education.—The reigning family, as well as the majority of the inhabitants of Hesse-Cassel, belong to the Reformed, or Calvinist Church. According to the last census, there were 373,599 Calvinists; 133,800 Lutherans; and 102,486 United Evangelicals—altogether 609,885 Protestants. The Roman Catholics numbered 107,695, and the Jews 16,358. The affairs of the Reformed Church are managed by three consistories, at Cassel, Marburg, and Hanau; while the Lutherans are under a general superintendent, appointed by the minister of the interior. The United Evangelicals carry on their own ecclesiastical government by a central committee and occasional synods. A Roman Catholic bishop, at Fulda, is at the head of the Catholic Church. The clergy, in general, have very little influence, and are ill-paid and of small social consideration.

Until recently, Hesse-Cassel was somewhat behind

the neighbouring German states in education; but within the last few years great improvements have been made in this respect. Numerous elementary schools have everywhere been established, and although education is not compulsory, there are few grown-up persons to be met with who are unable to read and write. The upper educational establishments comprise the University of Marburg, the Military and Polytechnic School at Cassel, and the Theological Seminary at Fulda. The latter is for Roman Catholics; while the Protestants have similar establishments at Cassel, Marburg, and Hanau. The University of Marburg, founded in the year 1527, has, on the average, between three and four hundred students.

Revenue and Expenditure.—The budget period embraces a term of three years. The annual revenue and expenditure are each about 750,000*l*. The public debt is about 1 $\frac{3}{4}$ millions sterling. The whole financial state of Electoral Hesse is as yet very imperfectly known; most of the former governments refusing to give a specific account of the management of the 'state property,' including crown-lands, forests, mines, and other important sources of revenue. It has been stated in the Chamber that, under proper administration, and 'absence of high speculation,' the income from these sources would be abundantly sufficient to pay the whole of the public expenditure.

Army.—The army is formed by annual conscription, with permitted substitution. The nominal term of service is five years, reduced in practice to little more than one. Organized on the 'peace footing,' and actually under arms, are the following troops:—Four regiments of infantry, 5770 men; one brigade of cavalry, 988 men; one regiment of artillery, 651 men: total, 7409 men.

The population of the country was 567,866 in the year 1818, and kept on slowly increasing till 1849, when came a period of decline. The census of 1849 showed a population of 759,751, which had sunk in 1852 to 755,350. The next census of 1855 showed a further diminution to 736,392, or a loss of 18,958 souls. The census of 1858 registered the disappearance of another 10,000 inhabitants. Thus, in nine years, the country lost nearly five per cent. of its population, chiefly by emigration to North America.

When the Congress of Vienna remodelled the titles of the German sovereigns, the ruler of Hesse-Cassel was offered the appellation of grand-duke, which, however, he refused, requiring to be made either a king or to remain an 'elector,' although the latter name had become quite unmeaning by the destruction of the Germanic empire. Nevertheless, he was allowed to retain the title, which he had obtained from Napoleon I. in 1805, in exchange for that of landgrave.

The reigning family possess a large private fortune, acquired chiefly by the sale of their subjects in the last century. During the American war, from 1776 to 1784, Landgrave Frederick II. sold to the British government between twenty and thirty thousand Hessians, by which transaction he is said to have gained above two millions sterling. The son and successor of Frederick II., Landgrave William IX., when flying before the anger of Napoleon I., invested his money with a Hebrew merchant of Frankfurt, Anselm Rothschild, whom he appointed his 'hof-agent.' Having made the fortune of the latter, and

laid the foundation of his 'house,' the landgrave left his own heirs the sum of 60,000,000 thalers, or 9,000,000*l*. Notwithstanding this vast personal property, the reigning family have continually refused their consent to the transfer of the public domains to the state. A small portion only of these estates contributes to the revenue.

Hesse-Cassel occupies the eighth place in the German Confederation, and has three votes in the *Plenum*, or general council of the Diet.—(Milner's *Gallery of Geography*, 1864; *Statesman's Year-Book*, 1866; *Almanach de Gotha*, 1866, &c.)

HESSE-DARMSTADT, the grand-duchy of which is governed by the second main branch of the house of Hesse, was founded in 1567 by George I., on whose death his dominions were divided among his three sons. Louis V. succeeded him in the principal line; Philip obtained Butzbach, which reverted on his death to the main line; and Frederick, the youngest, was the founder of the junior line of Hesse-Darmstadt, namely, that of Hesse-Homburg. Excepting the ruinous effects of the Thirty Years' War, the reigns of the succeeding princes were on the whole prosperous, and various acquisitions of territory were made. Louis IX., who reigned from 1768 to 1790, was a friend of peace and a patron of the arts and sciences. He found the country burdened with a large debt, which he paid off, and left to his son, Louis X., an improved territory with 300,000 inhabitants. This prince, during his long reign of forty years, was a greater gainer than almost any other German sovereign by the French revolution; he acquired very large additions to his dominions, and first assumed the title of grand-duke as Louis I. In 1815 the grand-duke joined the German Confederation. His son and successor Louis II. was engaged in continual disputes with the Estates; and disturbances, in some instances attended with bloodshed, broke out on different occasions. He died in June, 1848, and was succeeded by his son, the present grand-duke, Louis III., born June 9, 1806.

The grand-duchy of Hesse-Darmstadt consists of two large portions, which are separated from each other by a long strip of land, extending from east to west, belonging to Hesse-Cassel and the city of Frankfurt. It is situated between 7° 50' and 9° 40' E. long., and between 49° 12' and 51° 20' N. lat. The northern portion is bounded W. by Prussia and Nassau; N., E., and S. by Hesse-Cassel. The southern portion is bounded N. by Nassau, Frankfurt, and Hesse-Cassel; and on the other sides by Bavaria and Baden. The area of the whole is 3237 square miles, and the population in 1861 was 856,907.

Divisions.—The grand-duchy is divided into three provinces:—

I. STARKENBURG (322,744 inhabitants) contains 22 towns, 24 market villages, and 382 other villages. Darmstadt is the capital of the grand-duchy. [DARMSTADT.]

II. RHEINHESSEN, that is, RHENISH HESSE (234,491 inhabitants), contains 10 towns and 180 villages. The chief town is Mainz. [MAINZ.]

III. OBERHESSEN, or UPPER HESSE (229,672 inhabitants), contains 34 towns, 10 market villages, and 510 other villages. The chief town is Giessen. [GIESSEN.]

For the three years previous to 1855, the popula-

tion decreased to the number of 17,910; since then there has been a gradual increase. The illegitimate births amount, on the average, to above fifteen per cent.

Face of the Country, Soil, Climate, &c.—A large part of the surface of the country is mountainous. The banks of the Rhine, and the Wetterau, which contain about 400 square miles, are pretty level; the remainder of the country is traversed by branches of the Vogelsgebirge, the Odenwald, Taunus, and the Westerwald. Hesse-Darmstadt is on the whole an agricultural country. The soil is about the most fertile and best cultivated in Germany. The chief productions are corn of all kinds, likewise maize, flax, hemp, hops, tobacco, pulse, potatoes, wines, both white and red, garden vegetables and fruit, and timber. The southern districts, in which most of the fruit is grown, are specially noted for the excellence of their wines. Rhenish Hesse is nearly destitute of timber. The valleys of the Odenwald and Vogelsgebirge are well adapted to the breeding of cattle, of which there are large numbers. Swine are kept chiefly in Upper Hesse and Starkenburg. Mining is not carried on so extensively as might be expected: it is confined to copper, iron, coals, salt, and brown coal. Cobalt, basalt, lime, sandstone, marble, and slate, are found in different parts of the grand-duchy. The chief rivers are the Rhine (2500 feet broad at Mainz), and the Main, and next to these the Lahn, the Schwalm, the Nidder, the Ohm, and the Itter. The climate is cold, except in the valley of the Rhine.

Manufactures, Trade, &c.—The chief manufactures are of woollens, cottons and linen, leather, and hardware. There is also a trade in silks, paper, chemical products, and metals to a small extent. The most considerable manufacturing and trading town is Offenbach, which has two annual fairs. Mainz is the principal place for the transit trade. The exports consist of the agricultural productions of the country and of some manufactures. The imports are principally colonial and manufactured goods. Hesse-Darmstadt joined the Prussian commercial league in 1828.

The country is well supplied with good roads, and has also about 120 miles of railway. The steam navigation of the Rhine, Main, and Neckar affords still more extensive means of communication, but has the disadvantage of being partly or wholly closed in the winter months.

Constitution and Revenue.—The constitution bears date December 17, 1820; but was somewhat modified in 1848, and again in 1856. The legislative power is vested, in part, in two Chambers, called the Upper and Lower House of Representatives. The former is composed of the princes of the reigning family, of the heads of a number of noble houses, the Roman Catholic bishop, the chief Protestant superintendent, the chancellor of the University of Giessen, and a number of life-members, not exceeding ten, nominated by the grand-duke. The Lower House consists of six deputies of noble landowners; ten deputies of towns; and thirty-four representatives of villages and rural districts. The latter are chosen in a tripartite mode of election—the original voters first polling the ‘electors;’ these, in their turn, choosing ‘deputies,’ and these again the final repre-

sentatives. The Chambers have to meet at least once every three years. On certain occasions, both houses vote together, as when a proposition of the government has been accepted by one house, and refused by the other, and a final decision is to be arrived at.

The revenue amounts to about 750,000*l.* per annum, and the expenditure to nearly the same amount. The public debt is 1,300,000*l.*, the greater part of which was incurred for the establishment of state railways. The late grand-duke, Louis II., found his allowance of 581,000 florins, or 48,417*l.*, quite insufficient for his wants, and for many years there was a struggle between the government and the representatives of the country about the payment of the grand-ducal debts. These were ultimately discharged out of the public funds; but in 1855 the civil list was found to be in debt again to the amount of 1,100,000 florins, or 91,666*l.* The Chambers refused to pay this new debt; but after long debates it was agreed on ultimately to discharge the amount provisionally, deducting it gradually from the grants of the civil list. The latter was raised, at the same time, to 625,000 florins, or 52,083*l.*, besides allowances to the princes and the grand-ducal court, amounting altogether to 751,800 florins, or 62,650*l.*

Army.—The army is formed by conscription; the men serving for a nominal term of six years, of which two are in the reserve. The actual number of soldiers under arms does not amount to more than six or seven thousand, but in theory the following troops are supposed to exist on the ‘peace-footing’—Four regiments of infantry, 8851; two regiments of cavalry, 1420; one brigade of artillery, 1239; total 11,510 men. Previous to the French revolution, the landgraves had never more than 4000 men in their service, which number they increased to 9000, after having obtained the title of grand-duke.

Church and Education.—Hesse-Darmstadt has a good University at Giessen. There are also superior schools and various literary and scientific societies in the chief towns, and at least one elementary school in each commune. Public instruction has made rapid progress of late, especially in the province of Rhenish Hesse.

The members of the Lutheran church number 398,807; the Calvinists, 29,200; the United Evangelicals, 167,534; the Roman Catholics, 217,405; the Mennonites and other Christian sects, 3,925; and the Jews, 28,759. Three Protestant superintendents and a Roman Catholic bishop, at Mayence, direct the ecclesiastical affairs of the population.

In the reigning family of Hesse-Darmstadt, all the divisions of the Christian faith are represented. The grand-duke is a Lutheran, his eldest brother a Calvinist; his second brother and wife are Roman Catholics; his youngest sister, the empress of Russia, is a member of the Greek church; and the consort of his nephew, Princess Alice, a member of the church of England.

Hesse-Darmstadt supplies a contingent of 7227 men, with a reserve of 3000, to the federal army, occupies the ninth place in the German confederation, and has three votes in the *Plenum*, or full council, and one vote in the limited council. It is a limited monarchical state, and the succession is

hereditary in the female line in default of male issue. (*Statesman's Year Book*, London, 1866; *Almanach de Gotha*, 1866; Von Klöden's *Erdkunde*.)

HESSE-HOMBURG was a part of the landgraviate of Hesse-Darmstadt, till it came, in 1596, into the possession of Frederick I., youngest son of George I. Frederick Charles Louis succeeded to the government in 1751. In 1806, on the foundation of the Rhenish Confederation, he was obliged to give up the sovereignty to Hesse-Darmstadt, on which he became dependent. The Congress of Vienna, however, in 1815, not only restored to him the sovereignty of his ancient principality of Hesse-Homburg, but added to it the lordship of Meissenheim, on the other side of the Rhine. The landgrave therefore is now a sovereign prince, and was unanimously received in the year 1817 as a member of the German Confederation.

On the death of the last landgrave in March, 1866, the territory reverted to the grand ducal house of Hesse-Darmstadt, and Prince Louis of Hesse, the husband of the Princess Alice, became its ruler. The annual income is 150,000 florins, or 12,500*l.*, in great part derived from the sale of mineral waters, and the profits of the Homburg gaming-tables, which, however, Prince Louis will probably abolish.

The area of Hesse-Homburg is only 106 square miles, and it contains altogether but 26,817 inhabitants. The contribution to the confederated army is 333 men, with a reserve of 100. The public revenue in 1863 was 45,000*l.* and the expenditure 43,000*l.*, the debt at that time being 82,000*l.*

The whole legislative and executive authority is centred in the landgrave, who governs through a ministry, divided into five departments, including a secretary for war.

Divisions.—I. The circle of Homburg, which contains thirty-two square miles, and 13,111 inhabitants. The chief town, Homburg vor der Höhe, is situated 10 miles N. by W. from Frankfort-on-the-Main, under an eminence, on which the palace of the landgrave is built. The population in 1861 was 6987. The town is charmingly placed amidst the forest-clad hills of Taunus. It is much frequented for its mineral springs and baths, but it has the inglorious distinction of surpassing all the other gambling dens of Germany in the magnitude of its transactions. Various attempts have been made to suppress the gambling saloons, which are open at all hours of the day and night; but they yield such a large proportion of the revenue of the state that at present they exert their baneful influence as actively as ever.

II. The circle of Meissenheim, which contains seventy-four square miles, and 13,706 inhabitants. It lies between the Prussian province of the Lower Rhine, the Bavarian circle of the Rhine, and the principalities of Lichtenberg and Birkenfeld. The chief town, Meissenheim, contains 2758 inhabitants.

The former of these circles is a fruitful district lying on the slope of the Taunus mountains, and produces grain, wine, and timber: the latter is mountainous, and yields large quantities of coal and iron, and some excellent wine.

Hesse-Homburg is represented by Hesse-Darmstadt in the limited council of the Diet, but it has

one independent vote in the *Plenum*, or full council. The established religion is Protestant, and about 20,000 of the inhabitants belong to it.

HESSE-NES, commonly called ESSENES, one of the three great sects into which the Jews were divided in the time of Christ. They are not mentioned in the New Testament, but it has been conjectured that they are alluded to in Matt. xix. 12, Col. ii. 18, 23. Many particulars concerning the customs and religious opinions of this sect are given by Josephus and Philo.

The Essenes generally lived at a distance from large towns, in communities which bore a great resemblance to the monkish societies of later times. They had all things in common, ate at a common table, and were exceedingly abstemious, never partaking of food before sunset. They were clothed in white garments, abstained from wine, and generally led a life of celibacy. They sent gifts to the Temple, but never offered any sacrifices there. The Essenes were exemplary in their religious duties, and were particularly distinguished by their rigid observance of the Sabbath-day. They believed in the immortality of the soul, but not in the resurrection of the body, and maintained the absolute predestination of all events: they held the Scriptures in the greatest reverence, but considered them as mystic writings, and explained them allegorically. They also appear to have possessed sacred books, which explained the peculiar doctrines and practices of their sect.

The origin of this sect is uncertain, and their numbers were never considerable: according to Philo and Josephus, there were only 4000 in Palestine.

It has been supposed, with considerable probability, that the early Christians derived many of their customs and opinions from the Essenes.

HESY'CHIUS, the name of the supposed author of a valuable Greek lexicon, which contains chiefly short explanations of unusual Greek words, or forms of words, and technical terms. It was not known until the sixteenth century. The first edition was that of Aldus, 1513, folio; the most complete, that of Alberti, 1746, 2 vols. folio, of which the second volume was published by Ruhnkens in 1766. This edition has a copious body of Prolegomena, containing all that can be said concerning this author.

HESYCHIUS, named the Illustrious, of Miletus, lived in the sixth century, and wrote a universal history in six parts, from Belus down to his own age. Some extracts of it have been preserved, which, with an abridgment of the 'Lives of the Philosophers,' chiefly from Diogenes Laertius, are edited in one volume by Meursius, 1613. (Photius, *Bibl.*, 69.)

HETEROBRANCHIATA, M. De Blainville's name for the fourth order of his *Acephalophora*. The first family (*Ascidians*) is divided into two tribes:—1, Simple *Ascidians*, and 2, Aggregated *Ascidians*. The second family consists of the *Salpaceans*, and is also divided into two tribes:—1, The Simple (*Biphora*, &c.), and 2, the Aggregate (*Pyrosoma*).

HETERO'CERCAL, the term chosen by M. Agassiz to express a peculiar form of the tails of fishes, which affords a very obvious, and, as far as yet appears, a very correct indication of the geological age of formations. Among existing fishes the

tail is either simple, as in the eel; bifurcate, as in the salmon; expanded to a round figure, as in the wrasse; or unequally bilobate, as in the shark. It is to this latter irregular form of tail that the term Heterocercal is applied: the others, by way of distinction, are called Homocercal.

The peculiarity of the heterocercal fishes is that the vertebral column runs along the upper caudal lobe: in the other forms of tail it is symmetrically placed with respect to the posterior finny expansion. M. Agassiz has found this peculiarity of the tail, which is least common among living fishes, and confined to particular groups, to belong to every species of fishes, of whatever group, and however differing in other respects, which occur in strata older than the oolitic system, while in and above that system homocercal forms appear. It is therefore a characteristic of geological time; and, among the conjectures as to the relations of this form to physical conditions of the surface or laws of the animal economy, we prefer the opinion that it is one among several marks of the sauroid character of the fishes which lived in early geological periods. Some of the fishes of the oolitic rocks exhibit a slight inequality of the lobes of the tail, and some difference in the arrangement of the scales thereon, but without (we believe) the characteristic continuation of the vertebral column into the upper lobe. These may be thought to mark the gradual transition from the heterocercal to the ordinary types of structure. Lepidosteus, with sharks, and other cartilaginous fishes of the existing creation, which were ranked by Linnæus as 'Amphibia Nantes,' thus appear the few surviving representatives of organic forms which, in earlier periods of the history of the globe, were exclusively predominant. The heterocercal tail appears in the young of several well-known homocercal forms.

HETEROCERUS, a genus of pentamerous coleopterous insects established by Bosc. Latreille places it in his second section of his family *Clavicornes*, and forms of it a tribe under the name of *Acanthopoda*, on account of the flattened broad limbs armed with spines. These beetles have small oval depressed bodies, and eleven-jointed antennæ, the last six articulations forming a cylindrical club. They live in sand or mud, by streams or among marshes, burrowing in the ground by means of their spinous tibiae. When disturbed or alarmed they come out of their holes. The larvæ live in the same

situations with the perfect insects. Several species are found in Britain.

HETEROGANGLIATA. The *Heterogangliata* of Professor Owen comprise all the *Mollusca* of Cuvier, with the exception of the *Cirripeda*.

HETEROGENEOUS. [HOMOGENEOUS.]

HETEROMERA, the second section of coleopterous insects in the arrangement of Latreille, including such as have five articulations in the first four tarsi, and four in the two posterior. They are all vegetable feeders. Latreille divided the *Heteromera* into four groups: 1st, the *Melasoma*; 2nd, the *Taxicornes*; 3rd, the *Stenelytra*; and 4th, the *Trachelides*.

HETEROMYS, a genus of Rodents, which, in M. Lesson's opinion, may be advantageously used, though M. Desmarest proposed it without adopting it. The genus is described as having the cheek-pouches of the Hamsters, the general form of the body and tail of the rats properly so called, and the dorsal flattened spines of *Echimy*s, Geoff. Example, *Heteromys Thompsonii*, Lesson. Habits and size of a rat. Locality, the island of Trinidad.

HETEROSCHII ('other-shadowed'), an old astronomical term for persons living in such parts of the earth that their shadows at noon are always turned contrary ways.

HETMAN, a title given to the chief general of the old Polish armies; and now applied, by the czar of Russia, to the chief general of his Cossack forces.

HEUCHE'RA, a genus of plants belonging to the natural order *Saxifragaceæ*, and consisting of about sixteen species. *H. Americana* is a native of North America, where it has obtained, on account of its astringent properties, the name of Alum Root. It contains tannin, and it is to this principle that its astringent character is to be ascribed. The other species contain tannin, but are not used for any purpose in the arts or medicine.

HEVELIUS, JOANNES, or more properly JOANNES HEVEL, a Polish astronomer of great eminence, was born at Danzig, of a noble family, January 28, 1611. He applied himself almost exclusively to the study of astronomy. In 1641 he built an observatory in his own house, and furnished it with a quadrant and sextant of three and four feet diameter, together with large telescopes constructed by himself. His scientific pursuits did not, however, preclude his being elected consul in 1651, to which distinction his rank in society and philosophic character entitled him, and of which he continued to discharge the duties to the time of his death. In 1647 he published a description of the moon, under the name of 'Selenographia,' to which was added a representation of the other planets as seen by the telescope. In 1654 appeared his treatise 'De Motu Lunæ Libratorio,' in the form of a letter to Riccioli, wherein he gave an explanation of the libration of the moon. To these succeeded various other works, and in 1673 the first part of the 'Machina Cœlestis' was published. It was this last work which gave rise to a public controversy between Hevelius and Dr. Hooke. Hevelius always imagined that better observations could be made with plain sights than with telescopes. Hooke recommended the use of the latter. Halley was requested by the Royal Society of London to visit Hevelius at Danzig, and judge of

the goodness of his observations. This voyage, which was made in 1679, produced a report from Halley highly favourable to Hevelius. In 1679 he sustained considerable loss by the destruction of his house and observatory by fire. The whole of his instruments and library were destroyed, including most of the copies of the second part of his 'Machina Cœlestis,' which had only been published that year. This second part is now extremely rare. This accident appears only to have had the effect of increasing his ardour in the pursuit of astronomy, for he shortly after erected a new observatory, though on a less magnificent scale, and by 1685 he had another volume of observations ready for publication. He had now been occupied forty-nine years as an observer, and had attained sixty-three years, the climacteric, as it used to be called, of life, for which reason this volume (the last published during his lifetime) is entitled 'Annus Climactericus.' His posthumous works are 'Firmamentum Sobieskianum' (1690) and 'Prodromus Astronomiæ' (1691). He died at Danzig, universally respected, in 1687-88, and in his seventy-sixth year.

HEXACHORD, a name given by the ancient Greeks to a lyre of six strings; also to a scale of six sounds. The term hexachord was also applied to a system of musical scales now disused.

HEXAGON, a figure of six sides.

HEXAHEDRON, a solid of six faces.

HEXA'METER (ἑξ, 'six,' μέτρον, 'measure') is the most common form of dactylic verse. [DACTYLICS.] It consists of six feet, either dactyls or spondees, with no limit in their arrangements, except that the fifth is usually a dactyl, and the sixth invariably a spondee. Great part of the beauty of a long poem written in this measure depends on the varied cadences which may be produced by varying the cæsura. [CÆSURA.]

HEXAPLA, the plural of ἑξαπλοῦς, which means 'six fold,' was an edition of the Scriptures of the Old Testament prepared by Origen, which exhibited, in addition to the original Hebrew text, six Greek versions in as many parallel columns; namely, the Septuagint, that of Aquila, that of Symmachus, that of Theodotion, one found at Jericho, and one found at Nicópolis in Epirus. It also comprehended a seventh version of the Psalms. The Hebrew text was besides given both in Hebrew and in Greek characters: so that, properly speaking, there were eight columns in all, whence the work is sometimes called Origen's Octapla. Only some fragments of Origen's Hexapla remain, which have been collected and published by Montfaucon under the title of 'Origenis Hexaplorum quæ supersunt,' 2 vols. folio, Paris, 1713.

HEXHAM. [NORTHUMBERLAND.]

HEYDEN, JOHN VAN DER, a Dutch painter of external architecture, born at Gorcum in 1637 (some say 1640). The value of his early works is enhanced by their being adorned with figures by A. Van de Velde. He died in 1712 at Amsterdam.

HEYLIN, PETER, born in 1600 at Burford, in Oxfordshire, studied at Oxford, where he took his degree of D.D. He gave lectures on history and cosmography in that university; and afterwards, in 1625, he published his 'Microcosmos,' or description of the globe. Heylin was appointed chaplain in ordinary to King Charles I. On the restoration of

Charles II. he was made sub-dean of Westminster. He died in 1662. He wrote a number of works on the religious and political controversies of the times; among others, a 'Defence of the Church of England;' a 'Life of Bishop Laud;' a 'History of the Tithes,' and a 'History of the Sabbath.'

HEYNE, CHRISTIAN GOTTLOB, born at Chemnitz, in Saxony, in 1729, studied at Leipzig, and distinguished himself as a classical scholar. The chair of eloquence and poetry in the University of Göttingen having become vacant by the death of J. M. Gesner, Heyne was appointed to it in 1763. The department to which Heyne particularly applied himself was that of classical criticism and the illustration of the writings of the ancients, by showing how they ought to be studied with reference to the manners and character of their respective ages. He published his ideas on these subjects in his notes to the 'Bibliotheca' of Apollodorus, and afterwards in numerous dissertations inserted in the Transactions of the University of Göttingen. Heyne's 'Opuscula Academica,' 6 vols. 8vo., Göttingen, 1785-1815, contain many learned and valuable disquisitions on ancient history. Heyne published editions of Homer, Pindar, Diodorus Siculus, Epictetus, Virgil, Tibullus, &c., all enriched with ample commentaries. His 'Antiquarische Aufsätze,' in 2 vols., are essays on the history of ancient art. Heyne died at Göttingen at a very advanced age, in July, 1814. His life, which has been written at some length by his son-in-law Heeren (Göttingen, 1813, 8vo.), contains an account of the difficulties that this scholar had to encounter in early life.

HEYWOOD, JOHN, one of our earliest dramatic writers, lived in the first half of the sixteenth century. He was a favourite at the court of Queen Mary, but in the reign of Edward VI. he was accused of plotting against the government. He retired to the continent, and died about 1565, at Mechlin, in Brabant. Heywood's dramatic pieces 'may properly and strictly,' says Mr. Collier, 'be called Interludes—a species of writing of which he has a claim to be considered the inventor.' The earliest of them, 'A mery Play between the Pardoner and the Frere, the Curate and Neybour Pratte,' was not printed till 1533, but must have been written before 1521. In Dodsley's Old Plays will be found his 'Play called the Foure P.P., a new and a very mery Enterlude of a Palmer, a Pardoner, a Potycary, a Pedlar.' Among other productions bearing his name was a posthumous volume of 'Woorkes,' 1576, 4to., which contains proverbs in verse, and six hundred epigrams. In respect of them, and to distinguish him from a later play-writer, Thomas Heywood, he is not unfrequently called the 'Epigrammatist.'

HEYWOOD, THOMAS, a well-known dramatist who lived in the reigns of Elizabeth, James I., and Charles I. Of all his pieces about twenty-four are left, of which 'A Woman killed with Kindness,' published in Dodsley's Collection, is much admired.

HIBERNATION, the term used to indicate the winter sleep of certain warm-blooded animals. As the season approaches the temperature of their blood is lowered, and they gradually pass into the hibernating lethargy. The marmot, the bear, and the bat furnish examples. During hibernation the animal takes no food, breathes only at comparatively

long intervals, has its heat diminished, and all its vital functions reduced. The phenomena of hibernation are also observed in most reptiles and in some insects.

HIBERNIA. [IRELAND.]

HIBISCUS, a genus of plants of the natural family of *Malvaceæ*. The species, upwards of 100 in number, of this genus are chiefly herbaceous, though of a large size, but a few are perennial and arboreous. They abound in the hot parts of Asia and America, and also in Africa and the tropical islands. A few extend into Europe, North America, and the Cape of Good Hope. The species are remarkable, like the family to which they belong, for abounding in mucilage, and for the tenacity of the fibre of their bark, whence several are employed for many economical purposes in the different countries where they are indigenous.

The abundance of mucilage in some of the species renders them useful as articles of diet, as the unripe fruit of *H. esculentus*. So in India *H. longifolius* is similarly employed, and much approved of by many Europeans. The calyxes of *H. sabdariffa* as they ripen become of a red colour and are pleasantly acid, whence in the West Indies the plant is called Red Sorrel. The calyxes are employed there, as well as in India, for making tarts; and a decoction of them, sweetened and fermented, makes a cool and refreshing drink, much used in the West Indies. *H. Syriacus* and *H. Rosa-Sinensis* are known as ornamental plants.

The species of *Hibiscus* are chiefly useful for the tenacity of their fibre, and hence several are employed in rope-making. Thus *H. cannabinus* is cultivated everywhere in India in the rainy season for this purpose; and its fibre is often imported into Europe as a substitute for hemp. In the island of Otaheite rope and string are manufactured from the bark of *H. tiliaceus*, which is also made into matting of a white colour, and of different degrees of fineness. Almost all the species possess sufficient tenacity of fibre to be used for cordage, whips, &c. They also abound in mucilage, which renders them serviceable as articles of diet.

Hibiscus abelmoschus, so called from *hab-al-mooskh*, the Arabic name of its musk-scented seeds, is now often named *Abelmoschus moschatus*, and formed into a new genus. Its seeds are said to be added to coffee in Arabia, and are in India employed as a cordial medicine.

HICCUP, or **HICCOUGH**, a spasmodic movement in the throat, caused by some internal derangement of the stomach. When a breath is taken, a sudden constriction of the glottis prevents its ingress, and simultaneously something rises in the throat which causes exhalation, and produces a peculiar sound in the larynx. The convulsions usually last only a few minutes, but cases have been known of hours' and even days' duration.

Simple remedies will sometimes cure hiccup, as holding the breath, eating a piece of ice, strong pressure at the waist or wrist, but in severe attacks chemicals, such as ammonia, camphor, or chloroform, must be resorted to.

HICKES, **GEORGE**, an English divine and philologist, was born June 20, 1642, at Newsham, in Yorkshire. He was sent to Oxford. In 1665 he

became M.A., and in 1679 D.D. at Oxford, having received the same degree the year previous from the University of Glasgow.

Between 1679 and 1683 he had several preferments, and in August of the latter year was made dean of Worcester. In 1688 he refused to take the oaths of allegiance, and was eventually deprived. He was subsequently consecrated suffragan bishop of Thetford by Archbishop Sancroft. He died December 15, 1715.

The work which goes by the name of his 'Thesaurus, or Treasure of the Northern Tongues,' in three volumes folio, Oxford, 1705, is that which is most likely to sustain his literary reputation.

HICKORY. [CARYA.]

HIDAGE, among our Anglo-Saxon ancestors, an extraordinary tax payable on every hide of land. Thus when the Danes invaded England, in 994, King Ethelred levied a tax by hides on all his lands, in order to enable the inhabitants to arm in defence of the kingdom. From every 310 hides sufficient was then raised, in provisions, money, and materials, to furnish one ship.

HIDALGO, in Spain, a man of noble birth.

HIDES. [LEATHER.]

HIDGELLE, a district of British India, in the presidency of Bengal, between lat. 21° 36' and 22° 22' N., and long. 87° 22' and 88° 12' E. It is inclosed by the river Hooghly, Bay of Bengal, Balasore, and Midnapore. The area is 1014 square miles, and the population 133,265. It is watered by the Hooghly, Roopnarain, Russoolpoor, and the Hulses; and has a great extent of sea-coast. Some parts are overgrown with jungle, affording harbour for tigers, leopards, and other fierce animals. Turtle, oysters, crabs, and prawns abound on the sea-coast. The climate is moist and unhealthy; and fevers, ague, and dysentery prevail. The chief crops are rice, millet, mustard, tobacco, sugar-cane, pulse, castor-oil plant, sweet potatoes, cocoa-nut palm, and the toddy-palm. There are also some salt-works.

HIERACIUM, a genus of plants belonging to the natural order *Compositæ*. There are nineteen British species of this genus, but none of them are valuable on account of the properties they possess.

HIERARCHY, literally 'a sacred government,' and generally applied to the whole ecclesiastical establishment of a church in all its gradations and orders. The word is strictly applicable only to episcopal churches, such as the Roman Catholic and Anglican, in each of which the hierarchy consists of bishops, priests, and deacons. These constitute what is commonly called the hierarchy of divine right; while those offices which are established solely by ecclesiastical ordinance, such as primates, patriarchs, metropolitans, cardinals, archdeacons, &c., are distinguished as the hierarchy of ecclesiastical right or jurisdiction.

HIERES. [HYE RES.]

HIEROCHLOE, a genus of grasses belonging to the *Phalacideæ*. One species only of this genus, the *H. borealis*, has been found in Great Britain.

HIEROCLES, the name of several Greeks:—

Hierocles, a lawyer, wrote a work on veterinary medicine, addressed to Cassianus Bassus, of which three chapters are preserved in the sixteenth book of

the 'Geopónica,' published by Needham, Cambridge, 1704, pp. 424, 425.

Hierocles, who probably lived in the sixth century, was the author of a work entitled 'Synecdēmos' (συνεκδήμος), that is, 'a travelling companion,' which gives an account of the provinces and towns of the Eastern Empire. The 'Synecdēmos' is printed by Wesseling in his 'Vetera Romanorum Itinera,' Amsterdam, 1735.

Hierocles, præfect of Bithynia, and afterwards of Alexandria, wrote two books against Christianity, entitled 'Truth-loving Words to the Christians.'

Hierocles, a celebrated Alexandrine philosopher of the fifth century, wrote a Commentary upon the Golden Verses of Pythagoras, which is still extant; and also a Discourse on Foreknowledge and Fate, of which Photius has preserved large extracts. A complete edition of his works was published by Needham, Cambridge, 1709. The Discourse on Foreknowledge and Fate was translated into French by Regnaud (Lyon, 1560).

There is also another work, entitled 'Asteia' (ἀστεία), containing an account of the ridiculous actions and sayings of pedants and silly persons.

HIEROGLYPHICS, a compound Greek word meaning 'sacred engravings,' generally applied to the representations of animal and other forms sculptured on the monuments of Egypt, by means of which the Egyptians expressed their language. The ancient Greek authors call this mode of writing *hieroglyphic* or *hierographic*, and attribute its invention to Thoth, the Egyptian Hermes. According to these authorities, it was the most ancient mode of writing known to mankind. It was called by the Egyptians *Neter tu*, or 'sacred words,' and was particularly used in all inscriptions relating to the gods, temples, and public events. Above 1000 different symbols appear on examination of the monuments to have been employed, and future observations will probably still further augment their number. They are arranged with great precision on the monuments, generally in horizontal or vertical lines, with all the animals and symbols of the same inscription facing in the same direction, whether to the right or to the left; sometimes, however, they are placed in the area or field, and dispersed amongst the figures or scenes they are intended to illustrate. They have been divided into six classes:—1. Sculptured and not painted; 2. those which are sculptured and painted; 3. *linear*, or drawn in outline; 4. drawn in outline and painted; 5. *polychrome*, or those painted with many colours; 6. *monochrome*, or those painted in one colour. Those carved on stone are generally executed in a peculiar kind of sculpture called *cavo rilievo*, in raised relief below the surface, but sometimes in bas-relief. The linear hieroglyphics are drawn with a carbonaceous black or a vermilion red ink on papyri, linen, slices of stone, wood, and other materials.

Hieroglyphics appear in use on the walls of the earliest tombs, and even scrawled on the blocks of stone of the great pyramid built by Cheops, and they continued to be employed till the time of Caracalla, during a space of almost 3000 years, but subsequently were superseded by a more cursive writing called the Demotic, and finally, on the triumph of Christianity, by the modern Coptic. Crude notions of the nature

of the hieroglyphs prevailed till Dr. Young, in 1818, first gave out the idea that they were used as sounds in royal names. He recognized the name of Ptolemy on the Rosetta stone; and the removal by Banks of a small obelisk from Philæ in 1822, enabled Champollion to compare the names of Cleopatra and Ptolemy, when it was seen, from the recurrence of the same hieroglyphics in the same places, as if they were used as sounds, that this was their true employment, and that the signs were purely alphabetic, not syllabico-alphabetic. By an extension of the decipherment, the names and titles of the Ptolemies, Roman emperors, and native monarchs were readily discovered.

Since the time of Champollion, who published a grammar in 1836, and 'Dictionary of Hieroglyphics' in 1841, the study has been pursued by Rossellini, Salrolini, Leemans, Lepsius, Brugsch, De Rouge, Birch, Goodwin, Layard, Hincks, and others.

The general result of their inquiries has shown that all hieroglyphic inscriptions, from the most remote to the latest periods, consist of two classes of characters, the first called by the Egyptologists *ideographs*, or symbols representing ideas, not sounds; and *phonetics*, or hieroglyphics employed as letters of the alphabet. The great body of the inscriptions are composed of phonetics, to the extent of four-fifths at least of each entire text; and they are easily distinguished by their constant recurrence. They are, however, fewer in number than the ideographs. The lapidary inscriptions are almost all religious, historical, or sepulchral. Even verse or rhythm has been found, and the expressions are often flowery with oriental imagery, antithesis, and metaphor.

Besides the Egyptians, the ancient Ethiopians also carved hieroglyphics on their pyramids and public monuments. At Nineveh, Koyunjik, and even in the isles of the Greek archipelago, objects have been found with hieroglyphical inscriptions not in the Egyptian language—perhaps unmeaning imitations, like the obelisks erected by the Roman emperors.

The term hieroglyphics has also been applied to the writings and paintings of the ancient Mexicans, by which they depicted the various occurrences of life. A symbolical system of pictorial writing prevailed in Central America and Yucatan before their conquest by the Spaniards.

Astrologers and almanac makers of modern days applied the word hieroglyphics to the symbolical pictures by which they pretended to show the events likely to happen in the course of the year.

For the principal works on hieroglyphics the reader is referred to Young, 'Account of Discoveries in Hieroglyphical Literature,' Lond., 1820; Champollion, 'Précis du Système Hiéroglyphique,' Paris, 1824; Grammaire Egyptienne, Paris, 1836; Birch, 'Introduction to the Study of Hieroglyphics,' Lond., 1837; Chabas, 'Papyrus Magique d'Harris,' 1861.

HIEROGRAMMATISTS, among the ancient Egyptians, certain priests who presided over religion and learning. Their especial duties were to expound religious mysteries, and preserve the history and hieroglyphics of the land.

HIERON I. succeeded his brother Gelon, as tyrant or ruler of Syracuse, 478 B.C. After the death of Theron, prince of Agrigentum, Hieron defeated his son, Thrasydæus, who was soon after expelled by

his countrymen. Hieron took Naxos and Cátana, and, having driven away the inhabitants from both towns, he replaced them by Syracusan and Peloponnesian colonists. His chariots repeatedly won the prize at the Olympic Games, and his success on those occasions formed the theme of some of the odes of Pindar, who was his guest and friend. Æschylus, Simonides, Bacchylides, and Epicharmus were also well received at the court of Hieron, who was fond of the society of learned men. Hieron died at

Coin of Hieron I. British Museum. Silver.

Reverse.

Cátana, 467 B.C., and was succeeded by his brother, Thrasybúlus.

HIERON II., son of Hierocles, a wealthy citizen of Syracuse, and a descendant of Gelon, served with distinction under Pyrrhus, in his Sicilian campaigns. After Pyrrhus had abandoned Sicily, the Syracusan troops chose Hieron for their leader, and the senate and citizens ratified the choice, 275 B.C. By marrying the daughter of Leptines, a man of influence among the aristocratic party, he secured their support. Having led the army against the Mamertines, a band of Campanian mercenaries, whom he defeated, the main body of them returned to Syracuse, where, through the influence of Leptines, he was proclaimed king, B.C. 270. The Mamertines of Messana, being threatened by Hieron and the Carthaginians, applied to the Romans for assistance. The Consul Appius Claudius marched to Rhegium, and having passed the strait in the night, unobserved by the Carthaginian cruisers, he surprised Hieron's camp, routed the soldiers, and obliged Hieron to seek for safety in flight. The consul next attacked the Carthaginian camp with the same success, and this was the beginning of the first Punic War, 264 or 265 B.C. In the following year the Romans took Tauromenium and Cátana, and advanced to the walls of Syracuse, when Hieron obtained peace on condition of paying 100 talents of silver, and supplying the Roman army with provisions. He punctually fulfilled his engage-

ment, remained faithful to Rome during the whole time of the war, and by his supplies was of great service to the Roman armies. Hieron was included in the peace between Rome and Carthage, by which his territories were secured to him, and he remained in friendship with both states. The period which elapsed between the end of the first and the beginning of the second Punic wars, from 241 to 218 B.C., was most glorious for Hieron and most prosperous

Coin of Hieron II. British Museum. Copper.

for Syracuse. Commerce and agriculture flourished, and wealth increased to an extraordinary degree. Hieron paid particular attention to the administration of the finances, and issued wise regulations for the collection of the land tax, which remained in force throughout Sicily long after this time. He embellished and strengthened Syracuse, and built large ships. Archimedes lived under Hieron's reign. When the second Punic War broke out, Hieron continued true to his Roman alliance. He lived to see the battle of Cannæ, after which his own son Gelon embraced the part of the Carthaginians. Gelon, however, died, not without suspicion of violence, and Hieron himself, being past ninety years of age, died shortly after, 216 B.C., leaving the crown to his grandson, Hieronymus.

HIERONYMUS, grandson of Hieron II., king of Syracuse, succeeded him on the throne at the age of fifteen (B.C. 216). The court of Syracuse, which under Hieron was orderly and respectable, soon became as profligate as it had been under the younger Dionysius. After the battle of Cannæ, Hieronymus declared war against the Romans, but a conspiracy broke out among his soldiers, and he was murdered, after a reign of thirteen months. On this news a popular insurrection took place at Syracuse, the daughters and grand-daughters of Hieron were murdered, and royalty was abolished.

HIEROPHANTES, a name applied to the high priests of the Eleusinian mysteries, who for many ages were chosen from the family of the Eumolpidae. The term was also applied to the priests or priestesses who had the care of the sacrifices and sacred things.

HIERRO. [CANARIES.]

HIGH BAILIFF, an officer who discharges min-

isterial duties, such as serving writs, &c., in certain liberties and parishes out of the jurisdiction of the sheriff.

HIGH COMMISSION COURT, a tribunal established by Queen Elizabeth under the authority of a clause in the Supremacy Act (1 Eliz. c. 1), which exercised arbitrary power in matters of faith and in ecclesiastical concerns, as the Star Chamber did in civil affairs. The commissioners were forty-four in number, of whom twelve were ecclesiastics; and three commissioners constituted a quorum. It exercised its powers without control, and was authorized to resort to the rack, to torture, inquisition, and imprisonment, and to proceed, not upon information, but at discretion, upon rumour and suspicion.

In 1641, this court and the Star Chamber were both abolished. James II. issued a new commission, but the Revolution swept away this arbitrary institution.

HIGH CONSTABLE. [CONSTABLE.]

HIGH-PLACES, a term frequently mentioned in Scripture history as applying to certain elevated places or eminences, where the idolatrous ceremonies of the Assyrians, Phœnicians, and other early Asiatics were performed; and where the use of religious temples was deemed irreligious and unlawful.

HIGH PRESSURE STEAM ENGINE. [STEAM ENGINE.]

HIGH SEAS, a term meaning the open sea, or that which is common to all countries. As a rule, every country has exclusive sovereignty over the sea to the extent of three miles from its shore; beyond that distance, and at any part which is more than three miles from any other country, is not the property of any particular country, and is technically termed the high seas. The rule as to the sovereignty within three miles is strictly observed with regard to fishing, except where special arrangements are made, but does not in any way restrict navigation.

HIGH TREASON. [TREASON.]

HIGH WYCOMBE. [BUCKINGHAMSHIRE.]

HIGHGATE. [MIDDLESEX.]

HIGHLANDS, the name given to the chief mountainous districts of Scotland. It is customary to speak of the *Northern Highlands* and the *Southern Highlands*. The former include tracts on the borders of Caithness, large portions of Sutherland, Ross, and Inverness shires, and Perth, Argyll, and Stirling shires. The latter take in part of Berwick, Peebles, Selkirk, Dumfries, Lanark, and Wigton shires. The chief ranges in the north are the Grampians and Ochils, in the south the Pentlands, Lammermoors, and the Lowthers.

HIGHWAY. [WAY.]

HILARION, SAINT, the founder of monastic institutions in Palestine, was born at Tabatha, about 291. His parents, who were heathens, sent him at an early age to Alexandria, to pursue his studies. Having been converted to the Christian religion, he resolved to retire from the world. Accordingly, on his return to Palestine, he divided among his relatives the property which his parents had left him, and retreated at the age of fifteen to the desert country south of Gaza. After remaining in this place for twenty-two years, during which time he practised the greatest austerities, his reputation for sanctity became so great, that numbers resorted to him in order to

be cured of their diseases. He afterwards went to Egypt, and successively visited Sicily, Dalmatia, and Cyprus, where he died about the year 371.

HILARIUS, a native of Sardinia, was made deacon of Rome about 354. He is frequently mentioned by Jerome ('Adv. Lucif.') as a rigid Luciferian, a sect which derived its name from Lucifer, bishop of Cagliari, in Sardinia, who separated from the church on account of the absolution that had been granted to those Catholics who had become Arians during the reign of Constantius. Hilarius wrote several works in favour of the opinions of Lucifer, and is generally supposed to have been the author of a Commentary on thirteen of St. Paul's Epistles, which is usually printed with the works of St. Ambrose.

HILARIUS, SAINT, was born at Poitiers, of which place he was afterwards made bishop about 354. He is distinguished in ecclesiastical history by the active part which he took against the Arians during the reign of Constantius. He died in the year 367.

The most important of Hilarius' works are:—1, 'Twelve Books concerning the Trinity;' 2, 'A Treatise on Synods,' addressed to the bishops of France and Britain, in which he gives an account of the creeds which had been adopted by the Eastern churches since the council of Nice; 3, 'Three Discourses addressed to Constantius,' on the Arian Controversy; 4, 'Commentary on St. Matthew;' 5, 'A Commentary on the Psalms.' These commentaries are entirely taken from the commentaries of St. Augustin.

HILARIUS, SAINT, was born in 401, and became bishop of Arles (Arles) in 429, on the death of Honoratus. Hilarius was distinguished by the holiness of his life and his zeal for monastic institutions; but he is more known in ecclesiastical history on account of his controversy with Leo, bishop of Rome. He died in 449. The writings of Hilarius are lost, with the exception of a life of Honoratus, a letter to Eucherius, and a poem upon the beginning of Genesis, which are published by Quesnel at the end of Leo's works, Paris, 1675. His life of Honoratus has also been published by Genebrard, Paris, in 1578.

HILARIUS, a native of Sardinia, succeeded Leo I., or the Great, as bishop of Rome in the year 462. He had been employed by Leo in important affairs; among others he was sent as legate to the council of Ephesus, in 449, against the Eutychians, and was well versed in matters concerning the discipline of the church, which he displayed great zeal in enforcing. Hilarius died at Rome in 467.

HILARODI (Gr. *ἡλαρός*, 'to exhilarate,' from *ἡλάρος*, 'cheerful,' and *ὄδῳ*, 'a song'), among the early Greeks, a kind of itinerant poet-musicians, who went about reciting or singing little amusing poems or songs, generally accompanied with some instrument. They were not unlike the wandering bards of our early history. Their dress was white, and their heads were usually crowned with golden fillets. In the course of time they were introduced on the regular stage.

HILARY TERM, a name said to be derived from St. Hilarius, bishop of Poitiers, and now applied to the English law term during which the law courts

hold their sittings at Westminster in *banco*. It commences on the 11th and terminates on the last day of January.

HILDBURGHAUSEN. [SAXE MEININGEN.]

HILDEBRAND. [GREGORY VII.]

HILDESHEIM, a government in the kingdom of Hanover, consisting of the principality of Hildesheim, which forms the most southern part of Hanover Proper; of the principalities of Göttingen and of Grubenhagen, which form an isolated portion of Hanover, lying between Brunswick, Hesse-Cassel, and Prussian Saxony; and of the county of Hohnstein, another isolated district which lies S.E. of the preceding, and extends southwards from the Brunswick circle of Blankenburg into the Erfurt division of Prussian Saxony.

The area of the principality is 1750 square miles, and the population in 1866 was 366,766.

In the south the surface of the principality of *Hildesheim* is traversed by branches of the Harz. The soil is stony and not generally fertile. In the centre and north the surface is undulating, and the soil rich and fertile. The principal rivers are the Innerste, Leine, Ocker, Ecker, and Fuhse. The climate is healthy. The agricultural products are corn, garden vegetables, fruit, flax, hops, and timber; the mineral products are iron, coal, and salt. Linen is the principal manufacture.

The principal town is *Hildesheim*, the capital, which stands on the Innerste, and is a place of considerable extent, but very irregularly built. It is 18 miles S.E. of Hanover, on the railway to Harburg. The number of inhabitants at the last census was 17,134, of whom one-third were Roman Catholics. It is divided into the old and the new towns. There are seven gates; the ancient ramparts have been levelled and converted into public walks. The town is the seat of a Roman Catholic bishop. The cathedral, founded in 818 by Louis the Pious, has ten altars, very fine paintings on glass, magnificent bronze doors covered with bas-reliefs, and numerous antiquities, among which is a pillar of greenish marble, said to have been a Saxon idol, which now supports an image of the Virgin. There are three other churches, a consistory, and a college, belonging to the Roman Catholics; a Lutheran college and several chapels, deaf, mute, and lunatic asylums, numerous public schools, a council-hall, treasury, &c. There is a trade in coarse linen cloths and yarn, and large cattle fairs are held here. The other towns are—*Gosler*. [GOSLER.] *Peine*, N.E. of Hildesheim, which stands on the Fuhse, and has 3000 inhabitants: *Bokenem* on the Nette, a branch of the Innerste; population, 2500: *Alfeld*, on the right bank of the Leine, which has 2800 inhabitants; and *Elze*, a few miles W. of Hildesheim; population, 2146.

GÖTTINGEN and GRUBENHAGEN are described in separate articles.

The county of *Hohnstein* is covered by the Harz mountains, except towards the south, where it comprises a portion of the Goldene-Aue, which is fertile in corn, and well cultivated. The mountains are covered with forests or with pasture; great numbers of cattle are reared. Iron, copper, cobalt, manganese, coal, marble, limestone, &c., are among the minerals; but iron mines only are worked. The county is divided into two districts, named from the villages

of *Neustadt* and *Ilfeld*. Near *Neustadt* are the ruins of the castle of Hohnstein, from which the county is named.

HILL, AARON, was born at Beaufort Buildings, in the Strand, 1684–85. He was educated at Westminster School, and in his sixteenth year Lord Paget, who was a relation of his mother's, provided him with a tutor, with whom he travelled through a great part of the East. Having subsequently lost his kinsman's favour, he was engaged by Sir William Wentworth as his travelling companion through Europe. On his return he wrote in 1709 a History of the Ottoman Empire, and about the same time was made 'master' of Drury Lane Theatre. At this time he wrote his first tragedy of *Elfrida*. He died in 1749–50.

Aaron Hill wrote about fifteen dramatic pieces, of which only two are now remembered, '*Alzira*' and '*Zara*,' both of which are adaptations from Voltaire.

HILL, SIR JOHN, was born about 1716, and began life as apprentice to an apothecary in London, in which capacity he gained that knowledge of botany which is his only claim to honourable notice; though, being possessed of lively parts, industry, and impudence, he managed to obtain in his lifetime no little notoriety. He pushed his way into fashionable life; published a fashionable and scandalous newspaper called the *Inspector*; made, puffed, and sold quack medicines; and yet found time to compose a great number of works, many very voluminous, principally on botanical subjects. Hill obtained a Scotch diploma of medicine, and assumed the title of Sir John in virtue of a Swedish order of knighthood presented to him by the king of Sweden. He died in 1775. The following are some of his most considerable works:—'*History of the Materia Medica*,' 4to., 1751; '*General Natural History*,' 1748–52, 3 vols. folio; '*British Herbal*,' 1756, folio; '*Vegetable System*,' 1759–75, 26 vols. folio; '*Constitution of Timber from its Early Growth*,' folio, 1770.

HILL ROWLAND, a preacher of eccentric genius and apostolic zeal, sixth son of Sir Rowland Hill of Hawkestone, was born August 23, 1744. Educated at Eton and St. John's, Cambridge, he was ordained in 1774 to the curacy of Kingston in Somersetshire. Having for his friends Berridge and Whitfield, he entered upon a course of itinerancy, preaching in villages, and paying religious visits to prisons and work-houses. In 1782 he laid the first stone of Surrey Chapel, London, opened it in the following year, and was minister of that favourite place of worship for fifty years. He was one of the founders of the Bible Society, the Tract Society, and the London Missionary Society. He was also one of the earliest and most effective promoters of Sunday schools; and a powerful advocate of Dr. Jenner's method of inoculation. His preaching was in a style peculiarly his own, being often unable to restrain his drollery in the pulpit; and many anecdotes are told of his eccentricities. It savoured nothing of art, nothing of the schools, hardly any thing of study, but was all nature. He died April 12, 1833, and was buried under his own pulpit at Surrey Chapel.

HILL, ROWLAND, VISCOUNT, a distinguished English general, second son of Sir John Hill of Hawkestone, Shropshire, and a nephew of the cele-

brated preacher his namesake, was born August 11, 1772. He entered the army as ensign in the 36th, was aide-de-camp to Lord Mulgrave, General O'Hara, and Sir D. Dundas, successively. On the 1st January, 1800, he was appointed full colonel, and was in active service with his regiment in Egypt under Sir Ralph Abercrombie. He served in the campaigns of 1809, 1810, and 1811, under the duke of Wellington, and displayed such great talents as a commander that he was made a G.C.B., and elevated to the peerage in 1814. He commanded a division at Waterloo, and aided in the final repulse of the French; in the *melée* his horse was shot under him, and he narrowly escaped with his life. In 1827 he declined the offer of chief command of the army in India, but succeeded the duke of Wellington as commander-in-chief of the whole army in 1828. He presided at the Horse Guards until August, 1842, when failing health compelled him to offer his resignation, and Her Majesty, in recognition of his long and faithful services, raised him to the rank of viscount. He died at his seat of Hardwicke Grange, Shropshire, on the 10th December, 1842.

HILL, SIR ROWLAND, K.C.B., founder of the system of penny postage, was born at Kidderminster in the December of 1795. In 1832 he published his first pamphlet of note, entitled 'Home Colonies; sketch of a plan for the gradual extinction of pauperism, and for the diminution of crime.' In it was broached the scheme, often resuscitated since, for the settlement of able-bodied paupers on waste lands, by the cultivation of which the expense of their support would be saved to the state; and the theory was supported by references to the success of a similar experiment in the case of the paupers of Holland and Belgium. After this Rowland Hill was appointed secretary of the South Australian Commission, and aided in founding the colony of South Australia. It was in 1837 that he printed for private circulation his celebrated pamphlet, 'Post-office Reform, its importance and practicability,' and after gathering opinions and suggestions, he gave it to the public. The reforms proposed in the pamphlet included in their results increased speed in the delivery of letters, greater facilities for their despatch, and a simplification of the operations of the post-office. But their chief feature was the establishment of a uniform rate of a penny for each half ounce, whatever might be the distance traversed by the letter. He predicted that by the adoption of his suggestions, not only would enormous advantages be bestowed upon the public, but a net revenue of more than a million sterling would be procured from the post-office. Towards the end of 1838 a committee of the House of Commons reported in favour of the plan. On the 12th of July, 1839, a resolution was carried in the House approving of it, and an Act of Parliament embodying it was passed. The founder of the new system was appointed to the Treasury at a salary of 1500*l.* a year to superintend the execution of his plans; but after three years his services were dispensed with by the ministry of Sir Robert Peel. A public testimonial to Mr. Hill was proposed in 1844, and resulted in the presentation to him of the sum of 15,000*l.* In 1846, on the resumption of office by the Whigs, Rowland Hill was appointed secretary to the postmaster-general, and in 1854 sole secretary

to the post-office. This situation he resigned in February, 1864; the full salary attached to it being, however, continued, on account of his vast exertions in the cause of postal reform, for which also he was made a knight commander of the Bath, March, 1860.

HILLAH. [BABYLON.]

HILLIARD, NICHOLAS, limner, jeweller, and goldsmith to Queen Elizabeth and to James I., was born at Exeter in 1547. His father, Richard Hilliard, was high sheriff of Exeter and Devonshire in 1560.

There are many miniatures, especially of ladies, by Hilliard extant. He painted Mary queen of Scots, Elizabeth several times, James I., and Prince Henry. He had for twelve years the exclusive privilege of painting and engraving the portraits of the royal family. He died in 1619.

HILTON, WILLIAM, R.A., was born at Lincoln on the 3rd of June, 1786. His father, who was a portrait painter, died in 1822. Hilton was placed with J. R. Smith, the engraver, in London, in 1800; he obtained about the same time admission into the Royal Academy as a student, and in 1803 he exhibited at the Academy exhibition a picture of banditti, of extraordinary merit for so young a man. His early works were followed by a series of noble compositions, which greatly distinguished him from the majority of his brother labourers. However, neither his subjects nor his style were popular.

In 1814 he exhibited 'Miranda and Ferdinand bearing a Log,' and he was elected an Associate of the Academy in the same year: he was elected a member in 1820, when he exhibited his picture of 'Ganymede,' which he presented to the Academy as his diploma piece. In 1825 he exhibited his 'Christ crowned with Thorns.' Two years afterwards he succeeded Fuseli as keeper of the Academy, a post which he held until his death, December 30, 1839, in his fifty-fourth year.

Hilton died in possession of his best pictures. 'Sir Calpeine rescuing Serena,' exhibited in 1831, was purchased by subscription from Hilton's executors, for 500 guineas, and was presented to the National Gallery, where it now hangs. There are two works by Hilton in the Vernon Collection—'Rebecca with Abraham's Servant at the Well,' exhibited in 1829; and 'Edith and the Monks searching for the Body of Harold,' exhibited in 1834.

HIMALAYA MOUNTAINS, or *Himmäleh Mountains*, extend along the northern boundary of Hindustan, and they constitute likewise the northern boundary of the valley of Assam. They are situated between 27° and 35° N. lat., and 73° and 98° E. long. The entire length of the range is 1500 miles, and the breadth varies between 100 and 160 miles.

The range lies between two plains, a low and level one, drained by the Ganges and the Brahmapootra, and extending along its southern declivity, and the elevated table-land of Tibet, which lies to the north-east and north of the range. The mountains terminate on the plain of the Ganges, in a wall-like range from 4000 to 5000 feet high, which, however, is frequently broken by gaps through which the rivers escape that carry off the water collected in the interior of the mountain region.

The enormous masses are separated from each other by valleys, of which the best known are those

of Cashmere, the Indus, and the Sutej. During the summer these upper elevations are covered with a vigorous vegetation, and are used by the inhabitants of the lower valleys as pasture-ground; but during the greater part of the year they are buried in snow, and uninhabited. Through the valleys lie the few roads by which the plain of the Ganges communicates with the countries on the table-land of Tibet. Some of the mountain ranges are continually covered with snow. Their elevation varies considerably. The mean altitude is from 16,000 to 18,000 feet, but nearly fifty of the peaks are now known to be over 23,000 feet, including Mount Everest—the highest in the world—which is 29,002 feet.

These mountains have their southern or Indian base clothed with a dense and almost impenetrable jungle, which separates them from the plains of India. This belt diminishes in breadth as we proceed northwards, until it altogether disappears to the north of the Jumna, where, in the country of the Sikhs, cultivation is carried on close to the foot of the mountains. We have here the characteristics of a tropical climate, and with it tropical or Indian vegetation. The decrease of temperature being gradual as we ascend mountains, so is the disappearance of tropical forms in the Himalayas. Indian trees and shrubs soon disappear. On reaching the height of 5000 feet, scarcely any but European forms are visible. There is little change in the thermometer from night to morning, or from day to day, or week to week; and the temperature does not vary 10° of Fahr. for three months, or from the middle of June to the end of September. It is in those months that rice is cultivated in these mountains, as well as other tropical grains, together with a species of arum, which is one of the principal articles of the chiefly vegetable diet of the hill-people. [HINDUSTAN.]

Notwithstanding the apparent barrenness of much of the country on the declivities of the Himalayas, nowhere are the flocks of cattle more conspicuous for number and variety. The cold and dry atmosphere is particularly favourable to the shawl-goat. The sheep and goat are both used as beasts of burden, and the dog is of a large size, and, like the others, furnished with fine wool under the upper shaggy hair.

Himálaya is a Sanscrit word, compounded of *hima*, 'cold, or frost, or snow,' and *alaya*, 'abode.' (Wilson's 'Sanskrit Dict.'). The resemblance of the first part of the compound to the name of the Hæmus (Balkan), to the Greek *cheima* (χείμα), and the Latin *hiems*, is obvious. The Greek and Roman geographers were acquainted with this enormous mountain-range under the general name of *Imaus* or *Emodus*.

HIMANTOPUS, the generic name for the Long-legged Plover, or Stilt. [PLOVERS.]

HYMERA, a city in Sicily, was founded by the Zancleans of Mylæ in Sicily (Strab., vi. 272), and after existing for 240 years was destroyed by the Carthaginians, and its ornaments carried off. The inhabitants who survived established themselves at Thermæ, near the site of the ancient town (Cic., 'In Verr.,' ii. 35), and enriched their new abode with such works of art as they had saved from the wreck. Upon the capture of Carthage, Scipio restored to the people of Thermæ, of Gela, and other Sicilian towns,

those monuments of art of which they had been plundered in their wars with Carthage.

HIMMEL, FRIEDRICH-HEINRICH, a German composer, the reputed son of Frederic William II., of Prussia, was born in the duchy of Brandenburg in 1765. He was intended for the church, and studied theology in the University of Halle, but became so skilful in music that the king encouraged him to pursue the art as a profession, and settled on him a pension. He chose Naumann as his guide, with whom he made such progress that in two years he produced the oratorio of 'Isacco.' He then travelled into Italy, and at Venice brought out a pastoral opera, 'Il Primo Navigatore.' In 1794 he succeeded Reichardt as kapell-meister at Berlin, and in the following year produced his 'Semiramide.' The operas on which his fame chiefly rests are 'Fanchon das Leiermädchen' (Fanchon the Lyre-maiden), and 'Die Sylphen' (the Sylphs). His death took place at Berlin in 1804.

HINCMAR was born in France in 806. He was of a noble family, and nearly related to Bernard, count of Toulouse. At a very early age he was placed under the care of Hilduin, abbot of St. Denis. His talents and high birth brought him under the notice of the Emperor Lewis, the Meek. Hilduin, having fallen under the displeasure of his royal master was banished from the court, and retired to Saxony, accompanied by Hincmar. On the death of Hilduin, his successor Lewis again introduced him to the court of the emperor, who presented him with the government of the abbey of Notre Dame at Compiègne and St. Germer. Ebbonius, archbishop of Rheims, having been deposed, Hincmar was elected by the clergy and people to succeed him.

In 857 Hincmar composed his first great work on Predestination, the preface of which is the only part extant. A few years afterwards he wrote a second treatise on the subject of Predestination, which has been preserved.

In the year 862, and for several succeeding years, we find Hincmar engaged in controversy with the pope, to whose interference in temporal matters he offered a strong resistance. Some years after, however, Hincmar exercised the same firmness in defending the rights of the church against the encroachments of regal authority that he had shown in opposing the Roman pontiff.

Hincmar died December 21st, 882, at Eprenay, where he had gone to escape from the Normans, who were pillaging and overrunning the province. His works have been collected in two volumes folio by the learned Sirmond, Paris, 1645; and another volume was added to this collection by Cellot, in 1658.

HIND, the female of the stag or red deer. The term is also sometimes improperly applied to other species of deer.

HINDOO ARCHITECTURE. [HINDUSTAN.]

HINDUSTAN, that is, in the Persian language, the country of the Hindus, or Hindoos, is the name which has been adopted by geographers to designate that part of India, or the East Indies, formerly called the Peninsula within the Ganges, which extends from Cape Comorin to the Himalaya Mountains. As the long declivity of this extensive mountain-chain slopes towards the plains of Hindustan,

the Himalaya mountains are properly included in Hindustan. The seas which surround it on the S.E., S., and W., and the mountains which inclose it on the N.W. and N.E., mark distinctly its boundary on these sides. Hindustan extends from $8^{\circ} 4'$ to 35° N. lat., and from 66° to 92° E. long. Its length, north to south, is about 1900 miles, and its breadth along the parallel of 25° is about 1600 miles. The area, as deduced by the recent trigonometrical survey, is 1,309,200 square miles, or nearly twenty-five times that of England and Wales. This trigonometrical survey was designed by the late duke of Wellington, and commenced shortly after the fall of Seringapatam, and is without a parallel for extensiveness and accuracy. The coast-line of Hindustan amounts, according to a recent calculation, to about 4000 miles. Beginning with the innermost corner of the Bay of Bengal, to Chittagong, the coast for about 320 miles is traversed by the numerous mouths of the Ganges. Contiguous to the Hooghly branch of the Ganges, is the open Bay of Balasore, with a coast of 120 miles, terminating at Cape Palmyras. From this point the coast stretches S.W. to the mouth of the Kistna, about 420 miles, and is without harbours, except that of Coringa, near the mouth of the Godavery. From the mouth of the Kistna, S. by W., to Cape Calymere, about 430 miles, no harbour occurs, even for vessels of moderate size. From Cape Calymere, W.S.W., to Cape Comorin, about 160 miles, there is only the small harbour of Tuticorin. The coast, which stretches N.N.W., and afterwards nearly N., between Cape Comorin and the innermost corner of the Gulf of Cambay, about 1150 miles, contains a great number of small and several very good and safe harbours. The coast-line of the peninsula of Gujerat, about 380 miles, has several harbours for vessels of moderate size. The coast-line of the island of Cutch extends about 150 miles. The coast intersected by the several mouths of the Indus extends as far as Cape Monze, about 150 miles, but it cannot be approached by vessels of more than fifty tons' burden, except at the harbour of Kurrachee, which admits vessels of moderate size.

Physical Features, Climate, Productions, &c.—NORTHERN INDIA, the more strictly continental portion of the country, is comprised between the river Nerbudda on the south, and the chain of the Himalaya. It has very varied superficial features—mountains, plateau and lowland, forest, river, and waste—each developed upon a scale of great magnitude. There are plains of the richest alluvial soil, intersected by a network of grand streams, refreshed seasonally with abundant rains, bathed in the intensest sunshine, and clothed with bright green verdure; there are sandy or stony tracts, flats of hard baked clay, where the mirage is often observed; and there are salt morasses, the haunts of porcupines and vast flocks of aquatic birds.

The high mountains are on the borders, as the Himalaya, the natural boundary between India and Tibet. These are the loftiest highlands of the globe, culminating at the height of nearly five miles and a half, or 29,000 feet, above the level of the sea. A grass-covered marshy tract, followed by a belt of dry forest land above it, marks the approach to the outer edge of the elevated region. Both districts are

extremely unhealthy, inhabited by countless wild animals. They skirt the Siwalik hills, and other sub-Himalayan ranges of moderate elevation, on which are placed the sanitarium for troops. Passing these, the surface ascends rapidly, but the stupendous heights of the great northern barrier are eighty or ninety miles from the exterior ridge. Their aspect in the distant view is often not more magnificent than extraordinary, owing to clouds completely hiding the lower slopes from sight. Hence the peaks appear projected against the clear blue sky without a visible solid basement, either wholly silvered with snow, or partly patched and tipped, or, where the inclination is too precipitous for snow to find a resting place, their naked pyramidal masses of gneiss and granite are exhibited. Other important highlands, but of far inferior elevation, the Sulaiman mountains, run from north to south beyond the Indus, and, with the Hala range, form the western boundary of the country from the Beloochee and Afghan territories. Their loftiest summit, Takht-i-Sulaiman, or 'Solomon's Throne,' rises to 11,000 feet. On the southern side, parallel to the river Nerbudda, the Vindhya mountains form a line of separation between northern and southern India, but nowhere exceed the height of 6000 feet. These natural boundaries, respectively on the north, west, and south, inclose minor ridges, with the table-lands of Malwa and Rajasthan, and the vast lowland plains which stretch in a huge curve between the mouths of the Ganges and the Indus, along the course of the rivers. Of these plains, the Gangetic is a region of exuberant fertility, while that of the Indus has a diversified character, and embraces the sterile district of the Indian Desert, extending from the Punjab to the Runn of Cutch.

Among the rivers, the first place is due to the *Ganges*, as well from its utility as its magnitude, and from being within the limits of India from source to mouth, while the rival systems of the Brahmaputra and the Indus have a foreign origin. It chiefly traverses a north-eastern alluvial flat, stretching from the Punjab to the Bay of Bengal, on which the great water-course and its numerous tributaries, some of which exceed the Rhine in length and volume, are spread out like the intersecting veins of a leaf. Its basin is the best cultivated and most densely peopled portion of the whole country. The river is deemed specially sacred by the natives, whose dreams of an auspicious future existence are closely connected with the consignment of their ashes to its bosom. It issues from a bed of snow in the Himalaya, at the height of 13,800 feet above the sea, and makes a very rapid descent to a low level. This is gained at Hurdwar, upwards of 1300 miles from the mouth, where the river begins to be navigable for light passenger boats, and for larger craft about 100 miles lower down. But the navigation is carried on with difficulty, owing to rapids and shifting shoals, to avoid which, as well as to irrigate a district which has often been scourged with drought and famine, the great Ganges Canal has been constructed. At Allahabad, 840 miles from the sea, where the stream receives the Jumna, it is about a mile across, but varies greatly in breadth and depth through the whole of its course according to the season. At about 280 miles from the coast, branches are thrown

off on the right bank, several of which unite to form the *Hooghly*, on which Calcutta is seated, while the grand trunk passes on to link itself with the system of the *Brahmaputra*. The two great rivers commingle in a highly complex manner, ramify in numerous channels over an extensive area, divide it into islands by their intersection, and discharge themselves by at least twenty mouths. This deltoid region is swampy and unhealthy, densely clothed with trees and jungle, hence called the *Sonderbunds*, or woods. In these the tiger prowls and the rhinoceros roams, while the waters swarm with huge crocodiles. The *Brahmaputra*, 'offspring of Brahma,' has the upper part of its course in Tibet, but forms in the lower the eastern frontier in relation to India proper. Owing to the periodical rains, and coincident meltings of the snow in the Himalaya, both rivers are annually in flood, inundate vast tracts of country, and bring down an enormous quantity of sediment, which discolours the sea to the distance of sixty miles from the shore.

The *Indus* traverses the north-western side of the country, and has a longer flow than the Ganges, with a less extensive basin, somewhat prominently distinguished by arid features. It rises on the northern side of the Himalaya, at the height of 18,000 feet, proceeds at first to the north-west, but breaking through the mountains, inverts its course to the south-west, receives the waters of the Punjab, or 'five rivers,' collected into a single channel, and descends to the Arabian sea through several mouths. The river has a lengthened navigation, but owing to its inconstancy and general want of depth, its navigable value is far inferior to that of streams of scarcely half the magnitude. The flood-tide rushes into the *Indus* with impetuosity, and forms a *bore*, owing to the confined space. The water rises in a ridge of several feet, which is swept along with great violence, endangering craft on the surface, and inundating the low grounds on the margin. The ebb takes place as suddenly; and thus vast tracts are rapidly converted into navigable expanses and flats of mud. Parallel with the river on the eastern side, and diverging from it hundreds of miles, is the Indian Desert, which embraces upwards of 150,000 square miles. It is not entirely sterile, but contains at intervals tracts of cultivable land; and the sandy portions are generally overgrown with coarse grass and jungle shrubs after the rains. But this vegetation perishes completely in the hot months, and the true desert aspect is exhibited. Southward lies the Runn of Cutch, a remarkable flat district bordering the Gulf of Cutch, and through the greater part of the year without weeds or grass, sustaining only a few tamarisks. But during the monsoon, when the sea runs high, its waters are driven over it, leaving shallow salt-lakes behind; and the general surface receives a saline incrustation from the subsequent evaporation. SOUTHERN INDIA, the peninsular portion of country, called by the natives the *Deccan*, consists of an immense central plateau, broken by river-valleys into a series of table-lands, which range in elevation from 2000 to 3000 feet. They advance in height from north to south, and have a gradual slope from west to east, in which direction the important rivers have their course. Between this high country and the sea are lowland tracts, commonly distinguished as

the coast of Coromandel on the eastern side, and the Malabar coast on the western. The plateau has chains of mountains on its edges, called the Eastern and Western Ghauts, which run parallel to the shores, and converge southerly in the wild tract of the Neilgherries, or Blue mountains. This district contains the highest point of the peninsula, the peak of Dodabetta, which rises to 8760 feet, and is the seat of the principal sanitarium, owing to the temperate climate. Further south, the highland region is broken by the sharply defined valley or gap of Palghat, beyond which hilly ridges rise again, clothed with woods, and are continuous to Cape Comorin. The word *ghaut*, *gate*, is of Sanscrit origin, and refers to the terrace-like passes by which the ranges are crossed. The Western Ghauts form a lofty chain, through which no streams of the slightest consequence find their way from the central region to the sea. They present a very steep face towards the ocean, press closely to its border at various points, and contribute to give a bold character to the coastline, which has many convenient harbours. The Eastern Ghauts are lower, and are much less continuous, offering channels through which nearly all the drainage of the interior is poured. They are also at a much greater distance from the shore, which is uniformly low and without harbours, and exposed to the roll of a violent and dangerous surf. The *Godavery* (*Godávári*), the largest river, has a course of rather more than 850 miles. It rises in the Western Ghauts, and passes to the Eastern, flowing through them with such a gentle descent that the navigation is not interrupted, either up or down. The *Kistna* and *Kaveri* are next in importance, following the same general direction. The *Nerbudda*, on the north border of the peninsula, is the largest westward-bound stream, entering the Gulf of Cambay after a course of 800 miles. Neither Northern nor Southern India contains any extensive lakes, and the number of small size is few compared with the magnitude of the area. This is the chief exception to the oft-repeated remark, that the country may be regarded as an epitome of the whole earth.

The valleys and mountain-slopes are profusely adorned with splendid vegetation, varying from tropical to alpine forms according to the elevation, and combining all the materials requisite for utility, beauty, and luxury. The cocoa-nut palm, the palmyra palm, and other varieties of the tribe, tall bamboos, jungle grasses, tree ferns, and arborescent flowering-plants, are eminently characteristic of the flora at the lower levels, where heat and humidity combine their influence. Timber of the highest value is supplied by the teak, sandal-wood, satin-wood, ebony, and sapan trees; and in the belt of forest which skirts the southern base of the Himalaya remarkably fine trees are found. The greatest botanical variety is of course seen in the grand mountain-region, owing to the different climates met with ascendingly. From the height of 5000 to 8000 feet, oaks and rhododendrons compose the main mass of the forest—the latter not shrubs as with us, but trees of considerable size, bearing their splendid purple flowers. In association with them are the cypress, ash, birch, elm, holly, hornbeam, alder, and several laurels. Still higher, up to 11,500 feet, most of the preceding occur, but other objects are more prom-

inent, as pines, yew, horse-chestnut, walnut, maple, hazel, and the magnificent deodar. At a greater elevation, a few trees struggle for existence in a stunted condition, and with a deformed aspect. Shrubs grow at the height of 15,200 feet, and herbaceous plants at a loftier altitude, till you reach the point where all vegetable life ceases, and the eternal snow and azure sky alone are present.

The objects of cultivation to supply the daily wants of the natives, and meet the demands of commerce, illustrate by their diversity the bounty of nature in supplying vast tracts of deep black vegetable soil, with the other condition of seasonal rains and a high temperature to render it prolific. They include rice, the staple food, with other cereals; the sugar-cane, cotton-plant, mulberry tree for the silk-worm, poppy for opium, tobacco, indigo, coffee, and cinnamon; various medicinal shrubs, and flowering plants for perfumes; with an immense variety of fruits, among which the pine-apple, pomegranate, plantain, guava, melon, banana, and cocoa-nut are the most common. Several of the preceding are known ancient products of Indian agriculture.

The Greeks of Alexander's expedition noticed that garments of fine cotton were ordinarily worn by the great men of the country, either wrapped round the shoulders, or enveloping the head as turbans. The general food, pillaus made of rice, also attracted attention, as well as the mode of planting the rice in water, with the distillation of a strong spirit from it, the arrack of the natives. They remarked also the sugar, calling it honey made from canes, without the assistance of bees. We have the word 'sugar' from its Sanscrit name *sukkhar*, as also 'sugar-candy' from *sukkhar kund*.

In our own time the objects of culture have been increased by the growth of tea on the southern face of the Himalaya, with a success which has changed the aspect of entire districts, and is likely to convert a belt of country along the whole range into a large tea-plantation. The plant occurs there in the wild state, and was noticed in Nepal as far back as the year 1816, but was pronounced by some to be a camelia. It is probably the parent stock of all the varieties raised in the old tea-producing districts, China and Japan, since the wild shrub is not known in either of those countries. More recently, the Peruvian-bark trees have been introduced, in order to secure a supply of quinine independent of South America. The plantations on the Neilgherry hills succeed perfectly, and the bark thus grown is found to contain precisely the same alkaloids as the natural produce on the slopes of the Andes.

The fauna, like the flora, is distinguished by a great number of species, and the profusion of individuals. It includes also a remarkable proportion of animals of large size, and of the dangerous class. The elephant roams wild, but is very generally domesticated, carrying rajahs on state occasions, and obediently drudging in the service of the humblest menials. The rhinoceros is found in the secluded forests of Bengal; the lion occurs chiefly in the north-western provinces, Rajpootana and Guzerat; the tiger is general, from the jungles of the lowest levels up to the region of the snows and glaciers. Leopards, panthers, bears, hyenas, wolves, lynxes, and jackals are the more ordinary beasts of

prey. The wild ass inhabits the great sandy desert, and the camel is there the usual beast of burden, an office which the ox performs elsewhere. Monkeys abound everywhere, being held in religious respect by the natives, a distinction enjoyed also by the buffalo, wild and tame. The goat of Cashmere, a variety of the common species, is renowned for its very long, fine, and silky hair, of which the high-priced shawls are made. Reptiles comprise the poisonous cobra da capello, or black-hooded snake, the formidable python, and the gavia, or Gangetic crocodile. The birds, of which many are noted for splendid plumage or curious habits, are extremely numerous. Insect life is intensely developed as a consequence of the profuse vegetation, and includes myriads of the annoying or destructive class, such as locusts, white ants, and mosquitoes; the butterflies display the most gorgeous colours and forms.

From the earliest historic date Hindustan has been renowned for its mineral wealth, but entirely in relation to the possession of gold and gems. The precious metal occurs in a state of minute diffusion in many alluvial soils, and in the sands of many rivers; and some richly-auriferous reefs of quartz rock are known. Precious stones of great beauty and variety are also occasionally found, as diamonds, rubies, amethysts, chrysolites, topaz, beryl, and many others. Both iron and copper ores appear to be abundant along the base of the Himalaya. Rock-salt is plentiful in the Punjab. Coal is obtained in seven different localities, but the only field of importance at present known is the Burdwan, in the lower part of the valley of the Ganges. No coal-field has yet been discovered in the north-west provinces, or in Oude, the Punjab, or the Presidencies of Bombay and Madras, where it will be prudent to conserve the forests in the absence of native fossil fuel. But it is not unlikely that the geological survey of the country, now (1866) in progress, will develop within its limits a coal-producing power in some degree commensurate with its area, and adequate to the supply of its wants. The annual consumption at present, chiefly in manufactures and by vessels leaving the ports, may be estimated at 800,000 tons, towards which Hindustan contributes rather more than one-half, and the remainder is sent out from England.

The climate, generally, is distinguished by three well-marked seasons, the cool, the hot, and the rainy, which divide the year. The cool season extends from October till towards the close of February; the dry, hot season follows, and continues till the beginning of June; the great rainy season succeeds, and lasts with occasional intermissions till October. But during the cool period the heat is still great by day, though slight frosts occur in the elevated districts for an hour or two before sunrise, and a thin ice is formed. The greatest heat prevails on the lowlands of the Coromandel and Malabar coasts, and through the north-western sandy region. At Bombay the mean annual temperature is 84°, at Madras 83°, at Calcutta 77°, and at Delhi 72°. The monsoon winds are the peculiar features of the climate, but are common to the neighbouring regions from Africa to the Malay peninsula. They blow periodically from the south-west and north-east, maintain the same direction for nearly half the year, and regu-

larly succeed each other. The south-west monsoon commences about the middle of April, and continues till September. It brings on the great rainy season to the Malabar coast and the Gangetic plain, owing to the masses of vapour blown up from the ocean being arrested by the Western Ghats and the Himalaya mountains. The showers descend in deluges, and commence with violent thunder storms. The north-east monsoon follows with less decided features, and brings a rainy season to the Coromandel coast, usually lasting about two months. At different stations the rain-fall varies greatly in its amount. In the valley of the Ganges it does not differ much from that of Great Britain, being 64 inches annually at Calcutta, 41 at Benares, 27 at Allahabad, 20 at Delhi, and 32 inches at Meerut. But the quantity in other situations is enormous, amounting at Darjeeling, among the sub-Himalayas, to 122 inches, and at Mahabaleshwar, a sanitarium connected with Bombay, to 250 inches. Among the Cossya hills, in the valley of the Brahmaputra, but beyond the bounds of India proper, the annual fall is ascertained to be 610 inches, which is equal to 50 feet.

The political divisions of this great region, though extremely numerous and complex, may be arranged in five main sections:—1. The British Territory under the direct government of the crown; 2. Protected or Tributary States, which have native rulers, but are entirely subject to British control; 3. Independent States; 4. French and Portuguese possessions; 5. The island of Ceylon, a separate colony of Great Britain. The territory subject to direct British rule embraces considerably more than half the entire area of the country. The first and second of the above sections may be merged in one grand division, constituting British India, which comprehends the whole region from Cape Comorin to the Cyclopean walls of the Himalaya, with the exception of the comparatively insignificant tracts which are independent, or held by the French and Portuguese.

All the principal states and their chief towns are described in separate articles, and full particulars on every matter of general interest relating to British India will be found in the article **INDIA, BRITISH**.

Inhabitants of Hindustan.—A complete census of the people of Hindustan has not yet been taken. It was to have been done in 1861, but owing to the agitation occasioned by the mutiny, it was deemed inexpedient. Official estimates return the number of strictly British subjects at about 155,000,000. To these, it is supposed, must be added 40,000,000 for the inhabitants of protected states and independent territories, thus making a grand total for the entire population of nearly 200,000,000. In classifying this immense aggregate, Mr. Montgomery Martin conceives that aboriginal races, known by various names, and greatly scattered, number 20,000,000. The Mohammedans he reckons at from 12,000,000 to 15,000,000; the Sikhs, on or near the Sutlej, at about 2,000,000; the Jains or Buddhists, widely diffused, at 5,000,000; Hill tribes and sundry others at 8,000,000; the remainder, 150,000,000, being Hindus of the Brahmanical creed.

The aboriginal races are known by the various names of Konds, Bheels, Santals, Mairs, Koles, Bengies, Dornes, and Bhâts. They are found in

jungles, forests, mountainous districts, and the outskirts of towns; were formerly prone to live by plunder, and committed frightful excesses to obtain it, but many have been reclaimed by the care of the government, and now faithfully serve it as efficient soldiers and armed police.

Under the modifying influence of different climate, food, and other external circumstances, operating for ages, the Hindus have ceased to be a homogeneous people. Their diversities in appearance, character, habits, and language are now as great as those which exist among the various nations of Europe. In general, the figure is slight, graceful, and admirably proportioned, but muscular and athletic on the high table lands; the face is oval, and the features regular; the eyes and hair are black; the skin is soft and polished; the complexion varies from the deepest olive to a light transparent brown.

An indigenous form of municipal government of great antiquity is an interesting feature in the social life of the Hindus. Each of the *villages*, meaning thereby a district of varying extent analogous to a township, is under the jurisdiction of a head-inhabitant, called the *potail*. He acts as chief magistrate, arranges disputes, sees to the collection of taxes, and appoints the *chokeydars*, watchmen or police. Several other functionaries are recognized as of public utility, as the priest, the schoolmaster, the musician, and the dancing-girl, all of whom are paid at the expense of the community. Under this simple form of municipal government, the inhabitants have lived from time immemorial. The boundaries of the village have been but seldom altered; and though the villages themselves have been sometimes injured, and even desolated, by war, famine, and disease, the same name, the same limits, and even the same families have continued for ages! The indigenous rural police is effective in rendering petty thefts comparatively rare, and the poorer classes are content with the system, as it is from such minor offences that they principally suffer. But owing to the great extent of the country, with wild and uncivilized people in almost every part of it, some of whom are fiercely fanatical, an army of civil and military police is required for the repression of heinous crimes, and the maintenance of public order.—(Milner's *Gallery of Geography*, London, 1864.)

Ancient India as known to the Western Nations.—Commerce between India and the western nations of Asia appears to have been carried on from the earliest historical times. The spicery which the company of Ishmaelites mentioned in Genesis (xxxvii. 25) were carrying into Egypt, must in all probability have been the produce of India; and in the 30th chapter of Exodus, where an enumeration is made of various spices and perfumes, cinnamon and cassia are expressly mentioned, which must have come from India or the islands in the Indian Archipelago. This trade appears to have been carried on by means of the Arabs, who brought the produce of India from the modern Scinde or the Malabar coast, to Hadramaut in the south-western part of Arabia, or to Gerra on the Persian Gulf, from which places it was carried by means of caravans to Petra, where it was purchased by Phœnician merchants. Indian articles were also brought from the Persian Gulf up the Euphrates as far as Thapsacus, and thence carried

across the Syrian desert into Phœnicia. Europe was thus supplied with the produce of India.

The conquest of Idumæa by David gave the Jews possession of the harbour of Ezion-geber on the Red Sea, from which ships sailed to Ophir, bringing 'gold and silver, ivory, apes, and peacocks.' (1 Kings ii. 28; x. 11, 22.) Ophir was probably an emporium of the African and Indian trade in Arabia. The Arabian merchants procured the gold from Africa, and the ivory, apes, and peacocks, from India.

The produce of India was also imported into Greece by the Phœnicians in very early times. Many of the Greek names of the Indian articles are evidently derived from the Sanskrit. Thus the Greek word for pepper, *pepperi* (πέρρι), comes from the Sanskrit *pippali*; the Greek word for emerald is *smaragdos* or *maragdos* (σμάραγδος or μάραγδος), from the Sanskrit *marakata*. The name of cinnamon was introduced into Greece together with the article. (Herod., iii. 111.) Cinnamon is not Sanskrit. It is generally said that the Greeks obtained their tin, by means of the Phœnicians, from the Scilly Islands or Cornwall, but there is no direct proof of this; and it appears probable, from the Sanskrit derivation of the word, that the Greeks originally obtained their tin from India.

The western nations of Asia appear to have had no connection with India, except in the way of commerce, till the time of Darius Hystaspes, in B.C. 521. (Herod., iv. 44.) Darius, it is said, subdued the Indians, and formed them into a satrapy, the tribute of which amounted to 360 talents in gold. (Herod., iii. 94.) The extent of the Persian dominions in India cannot be ascertained.

The knowledge which the Greeks possessed respecting India, previous to the time of Alexander, was derived from the Persians; and such was the origin of the information contained in the third book of Herodotus (98-105). Herodotus had also heard of some of the natural productions of Hindustan, such as the cotton plant and the bamboo; but his knowledge was very limited. Ctesias, who lived at the court of Artaxerxes Mnemon for many years, has given us a fuller account than Herodotus of the manners and customs of the Indians, and of the natural productions of the country. He had heard of the war-elephants, and describes the parrot, the monkey, also cochineal, and other articles.

The expedition of Alexander into India first gave the Greeks a correct idea of the western parts of India. Alexander did not advance farther east than the Hyphasis; but he followed the course of the Indus to the ocean, and afterwards sent Nearchus to explore the coast of the Indian Ocean as far as the Persian Gulf. After the death of Alexander, Seleucus made war against Sandracottus, king of the Prasii, and was the first Greek who advanced as far as the Ganges. His expedition was the means of giving the Greeks a more correct knowledge of the eastern parts of India than they had hitherto possessed; since Megasthenes and afterwards Daimachus resided for many years as ambassadors of the Syrian monarchs at Palibothra (Sanskrit, *Pataliputra*), the capital of the Prasii. From the work which Megasthenes wrote on India, later writers, even in the time of the Roman empire, such as Strabo and Arrian, appear to have derived their principal

knowledge of the country. The Greek kingdom of Bactria, which was founded by Theodotus, or Diodotus, a lieutenant of the Syrian monarchs, and which lasted about 120 years (B.C. 255-134), appears to have comprised a considerable part of northern India.

After the foundation of Alexandria in Egypt, the Indian trade was almost entirely carried on by the merchants of that city; but few ships appear to have sailed from Alexandria to India till the supposed discoveries of the monsoons by Hippalus; and the Arabians supplied Alexandria, as they had formerly done the Phœnicians, with the produce of India. The monsoons must have become known to European navigators about the middle of the first century of our era, since they are not mentioned by Strabo, but in the time of Pliny were well known. Pliny has given us ('Nat. Hist.,' vi. 23) an interesting account of the trade between India and Alexandria, as it existed in his own time.

We have another account of the Indian trade written by Arrian, who lived in all probability in the first century of the Christian era, and certainly not later than the second. [ARRIANUS.] The 'Periplus of the Erythrean Sea' contains the description of the coast from the Red Sea to the western parts of India, and also gives a list of the most important exports and imports.

The knowledge which the ancients possessed of India beyond Cape Comorin was exceedingly vague and defective. The Romans never extended their conquests as far as India, nor visited the country except for the purposes of commerce. We read of embassies to Augustus Cæsar, sent by the Indian princes Pandion and Porus, and also of an embassy from the island of Ceylon to the Emperor Claudius.

We may form some idea of the magnitude of the Indian trade under the emperors by the account of Pliny (vi. 23), who informs us that the Roman world was drained every year of at least fifty millions of sesterces (upwards of 400,000*l.*) for the purchase of Indian commodities. The articles imported by the Alexandrine merchants were chiefly precious stones, spices and perfumes, and silk.

In the time of the Emperor Justinian, an Alexandrine merchant of the name of Cosmas, who had made several voyages to India, and afterwards turned monk, wrote a work still extant, entitled 'Christian Topography,' in which he gives several particulars respecting the Indian trade. Alexandria supplied the nations of Europe with Indian articles till the discovery of the passage round the Cape of Good Hope by Vasco de Gama in 1498. But the western nations of Asia were principally supplied by the merchants of Basra, which was founded by the caliph Omar near the mouth of the Euphrates, and soon became one of the most flourishing commercial cities in the East. In addition to this, a land trade, conducted by means of caravans which passed through the central countries of Asia, existed from very early times between India and the western nations of Asia.

History.—First period: From the earliest times to the Mohammedan Conquest.—The materials for the history of this period are very few and unsatisfactory. The only ancient history written in the Sanskrit language hitherto discovered, is a chronicle of the kings of Cashmere, entitled 'Raja Taringini,'

of which an abstract was given by Abulfazl in the 'Ain-i-Akbery.' The original Sanskrit was obtained for the first time by English scholars in the present century, and was published at Calcutta in the year 1835: an account of the work is given by Professor Wilson in the fifteenth volume of the 'Asiatic Researches.' But this chronicle gives little information respecting other parts of Hindustan.

The invariable tradition of the Hindus points to the northern part of Hindustan as the original abode of their race, and of the Brahmanical faith and laws. It appears probable, both from the tradition of the Hindus and from the similarity of the Sanskrit to the Zend, the Greek, and Latin languages, that the nation from which the genuine Hindus are descended must at some period have inhabited the central plains of Asia, from which they emigrated into the northern parts of Hindustan. But whatever opinion may be entertained respecting the origin of the Hindus, the Hindus never regarded the southern part of the peninsula as forming part of Aryavarta, or 'holy land,' the name of the country inhabited by genuine Hindus. Aryavarta was bounded on the north by the Himalaya, and on the south by the Vindhya mountains (Manu, vi. 21-24); the boundaries on the east and west cannot be so easily ascertained.

Hardly any thing is known of the history of Hindustan till the Mohammedan Conquest. After the overthrow of the Greek kingdom of Bactria by the Tartars, B.C. 126, the Tartars (called by the Greeks Scythians, and by the Hindus Sakas) overran the greater part of the north-western provinces of Hindustan, which remained in their possession till the reign of Vicramaditya I., B.C. 56, who, after adding numerous provinces to his empire, drove the Tartars beyond the Indus. This sovereign, whose date is pretty well ascertained, since the years of the Samvat era are counted from his reign, resided at Ayodhya and Canoj, and ruled over almost the whole of northern Hindustan from Cashmere to the Ganges. We also read of two other sovereigns of the same name, Vicramaditya II., in 191, and Vicramaditya III., in 441. The most interesting event in this period of Hindu history is the persecution of the Buddhists, and their final expulsion from Hindustan. [BUDDHA.] During this period many of the islands of the Indian Archipelago were colonized both by Brahmans and Buddhists.

Christianity is said to have been introduced into Hindustan in the first century. The first Christians who settled in any number in Hindustan appear to have been Nestorians, who went to the Malabar coast for the purposes of commerce. When Vasco de Gama arrived at Cochin, he found a great number of Christians, who inhabited the interior of Travancore and Malabar, and who had more than a hundred churches.

Second Period: History of the Mohammedan States.—The earliest invasion of the country by the Mohammedans was probably made in the latter part of the tenth century by Sabuktaghin, a Tartar soldier, who had been proclaimed by the army monarch of Ghizni. He passed the Indus, laid waste the province of Lahore, and returned to Ghizni laden with plunder. But he made no permanent conquests. He died in 997, and was succeeded by his son, the celebrated Sultan Mahmud, who is usually regarded as the first Mohammedan conqueror of Hindustan. He died in

1028, and was succeeded by his son Massud. Massud and his successors were unable to prosecute their conquests in the country, in consequence of the formidable enemies they possessed at home. Several Tartar tribes, denominated Seljukides, from the name of their leader, had been invited by Mahmud to settle in Khorasan. In the year 1171 Yeasuddin, king of Gaur in Khorasan, conquered all the countries west of the Indus which were subject to the monarchs of Ghizni, and compelled the reigning sultan to take refuge in Lahore. Lahore was taken by Mohammed, brother of Yeasuddin, in 1184, and Khosrou II., the last monarch of the house of Sabuktaghin, was put to death.

The Hindus, however, received no benefit from this change of dynasty. In 1191 Mohammed marched farther east, and, though he was at first defeated by the Hindu rajahs, he finally conquered the greater part of the northern provinces. In 1193 Delhi was taken, and made the seat of the Mohammedan government in India. Mohammed succeeded his brother Yeasuddin. The Gaurian dynasty ended in 1289, after having lasted 117 years.

The dominion now passed into the hands of the Afghans. During the reign of Firoz II., who succeeded Kai-Kobad, the Mohammedans first undertook the conquest of the Deccan. The invasion of Timur (Tamerlane) in 1398 overturned the already tottering power of the monarchs of Delhi. Timur did not remain in Hindustan more than a few months. In the reign of Ibrahim II., Baber, a descendant of Timur, invaded Hindustan, and put an end to the Afghan dynasty. In 1526 he took Delhi, and was the founder of the Tartar dynasty, or, as it is usually but erroneously called, the Mogul dynasty. Baber was succeeded by Humaïun, who had a troubled reign, and it was not till the accession of Akbar in 1556 that the Tartar (or Mogul) dominion in Hindustan was placed upon a firm basis. Akbar died in 1605, and was succeeded by his son Selim, who took the title of Jehanghir, i.e., 'conqueror of the world.' During the reign of Jehanghir, Sir Thomas Roe arrived at the court of Agra, and obtained from the emperor many advantageous grants to the East India Company. Jehanghir was succeeded in 1627 by Shah Jehân, during whose reign a great part of the Deccan was conquered by his son Aurungzebe. Shah Jehân was thrown into prison by Aurungzebe, in which he died at the age of seventy-four, January 21, 1666. He was succeeded by Aurungzebe, who had been proclaimed emperor in 1659. Aurungzebe was the last powerful sovereign that ruled over the Mogul empire of Hindustan. After the death of Aurungzebe in 1707, the Mogul dominion rapidly declined. The last sovereign, Shah Alum II., at last became the pensioner of the East India Company, which succeeded to the power of the Mogul emperors.

Third Period: History of the European Conquests.—The Portuguese were the first nation of Europe that obtained any dominion in Hindustan. Vasco de Gama landed with three ships at Calicut on the 20th of May, 1498. The Portuguese rapidly acquired extensive power in the country, and by their numerous settlements along the Malabar coast, especially at Goa and Diu, they monopolized the commerce with Europe. In the beginning of the seventeenth century, the English, Dutch, and French began to

make settlements along the coast; and the Portuguese lost their dominions almost as rapidly as they had acquired them.

The Dutch never acquired much political power in Hindustan, though at one time they carried on the greater part of the Indian trade. The French made several settlements, the chief one being at Pondicherry, of which they acquired possession in the latter part of the seventeenth century, and which soon became one of the most splendid European establishments in the country. [PONDICHERRY.]

For a history of the commencement and progress of British power in Hindustan, the reader is referred to the articles BENGAL and EAST INDIA COMPANY; and for the modern history of British India to INDIA, BRITISH. Much information will also be found under the names of the various presidencies and states, and of the Governors-general.

Languages.—The numerous languages spoken in Hindustan at the present time may be divided into two great classes: the one consisting of those languages which are derived from the Sanskrit, and which are spoken in the northern and central provinces; and the other comprising those languages which are unconnected with the Sanskrit, and which are spoken in the southern parts of the peninsula. The Sanskrit was the ancient tongue of the people, in which their sacred books are written, and though not now vernacular, it is cultivated by the learned. The chief dialects are Hindi, the language of the non-Mohammedan population; Hindustani, the most popular and widely used—it is Hindi corrupted by a mixture of Arabic and Persian words; the Bengali; Punjabi; Mahratti; Gujeratti, &c. But in many localities the English language is making progress, being taught in schools sustained by the government, and in mission seminaries.

The members constituting the family of languages which may appropriately be called the dialects of southern India are the high and low *Tamil*; the *Telugu*, grammatical and vulgar; *Carnātaca*, or *Cannādi*, ancient and modern; *Mālyāḷma*, or *Malayāḷam*; and the *Tuluva*, the native speech of that part of the country to which in our maps the name of Canara is confined. Besides these there are a few local dialects of the same derivation, such as the *Cōdugu*, a variation of *Tuluva*, spoken in the district of that name called by us Coorg. The groundwork of all these languages is the same.

There are also many mountainous parts and forests in the northern provinces of Hindustan inhabited by numerous tribes, who do not profess the Brahmanical faith, and who speak a language entirely unconnected with Sanskrit. These tribes, who are known by the names of Bheels, Gondas, and Puharees, inhabit the mountainous tracts in Candeish, Malwa, Rajpootana, Gondwana, and the Rajmahal hills in Bengal.

Castes.—The division of the Hindus into classes or castes, with fixed occupations, existed from the earliest times: the word caste is derived from the Portuguese word *casta*, 'race,' or 'lineage;' in Sanskrit they are called *varnas*, that is, 'colours.' The most ancient portion of the Vedas alludes to such a division; and in the laws of Manu, the Ramayana, the Mahabharata, and all the other Sanskrit works of the greatest antiquity, we find the system of castes fully developed.

All the Hindu writings recognize only four pure castes: Brahmins, Kshatriyas, Vaisyas, and Sudras. Pliny ('Nat. Hist.,' vi. 19) appears to have heard of the same number; but Megasthenes, from whom Arrian, Strabo, and Diodorus Siculus derive their account, mentions seven classes:—1, Philosophers; 2, agriculturists; 3, herdsmen and hunters; 4, handicraftsmen and artisans; 5, warriors; 6, public inspectors; 7, royal councillors. But Megasthenes has evidently separated into distinct classes individuals belonging to the same class: the public inspectors and royal councillors belonged without doubt to the Brahmanical class, as well as the philosophers; the agriculturists, herdsmen, and hunters, to the Vaisyas; and the handicraftsmen and artisans, to the Sudras.

The following extract from the 'Jatimala,' a Sanskrit work on Hindu castes, gives the common Hindu tradition respecting the origin of each caste. 'In the first creation by Brahma, Brahmanas proceeded, with the Veda, from the mouth of Brahma. From his arms Kshatriyas sprung; so from his thigh Vaisyas, from his foot Sudras, were produced: all with their females. The Lord of Creation, viewing them, said, "What shall be your occupations?" They replied, "We are not our own masters; O God, command us what to undertake." Viewing and comparing their labours, he made the first tribe superior over the rest. As the first had great inclination for the divine sciences (*Brahme veda*), therefore he was Brahmana. The protector from ill (*Kshagate*) was Kshatriya. Him whose profession (*Vesa*) consists in commerce, which promotes the success of wars for the protection of himself and mankind, and in husbandry and attendance on cattle, he called Vaisya. The other should voluntarily serve the three tribes, and therefore he became a Sudra; he should humble himself at their feet.'

A strong line of demarcation is drawn between the first three castes and the Sudras. The former are allowed to receive instruction from the Vedas, and are considered to have been born again in a spiritual sense, whence they are called regenerate. A Sudra, on the contrary, is not reckoned among the regenerate, and would, according to the ancient Hindu law, be put to death for reading the Vedas.

The caste which at present exists in Hindustan is very different from the above. With the exception of the Brahmins, the pure castes have disappeared; and the present class distinctions have had their origin in guilds, possession of property, particular districts, peculiar creeds, and similar accidental circumstances. Among the lower classes, caste has degenerated into a fastidious tenacity to the rights and privileges of station. They bind themselves to do certain things, and take care they will not exceed their particular duty. Men of all castes have risen to power, and those who lose caste can easily regain it, or at any rate, take a place in the next lower class. The caste of converts to Christianity is not now recognized by the missionaries. In fact, the modern system of caste is very similar to the social differences of the various classes in England. (Irving's 'Theory and Practice of Caste.')

Religion and Philosophy.—It is erroneous to suppose that the Hindus have always professed the same faith. The sects into which the Hindus are divided

in the present day are of modern origin; and the system of theology taught by these sects differs very much from the ancient religion of the people.

The whole of Indian theology is professedly founded on the Vedas, which are four in number: the Rig-, Yagur-, Sama-, and Atharvana-Veda. Only a small portion of them has hitherto been known to Europeans; and our principal information about them is a dissertation by Mr. Colebrooke, in the eighth volume of the 'Asiatic Researches.' A few of the hymns of the Rig-Veda were published, with a Latin translation, under the title of 'Rig-Vedæ Specimen,' by the late Dr. Rosen.

The original worship of the Hindus appears to have been addressed to the elements. In the Mantras, or prayers, which form the principal portion of the Vedas, Indra, or the firmament, fire, the sun, the moon, the air, the spirits, the atmosphere, and the earth, are the objects most frequently addressed. The mythology of the Vedas personifies the elements and the planets, and thus differs from the more recent legendary poems, which inculcate the worship of deified heroes.

The Vedas undoubtedly teach the belief of one supreme God. The deities invoked appear, on a cursory inspection of the Veda, to be as various as the authors of the prayers addressed to them; but according to the most ancient annotations on the Indian Scriptures, these numerous names of persons and things are all resolvable into different titles of three deities, and ultimately of one God. The name of this supreme deity, omnipotent, omniscient, and omnipresent, is *Brahmâ*, who is no longer an object of worship, but merely of devout contemplation. His attributes are represented by the three personified powers of creation, preservation, and destruction, which, under the respective names of *Brahmâ*, *Vishnu*, and *Siva*, form the *trimurti* (that is, 'three forms'), or triad of principal Hindu gods. These deities are sometimes represented singly with their respective attributes, and sometimes with one body and three heads. It would be impossible in our limits to give any account of the numerous inferior deities, which are said to amount, according to the computation of the Hindus, to 330 millions.

The worship of these gods, as well as of numerous others, which was once very popular in Hindustan, has almost entirely disappeared, in consequence of the exclusive worship which is paid to *Vishnu*, *Siva*, *Satki*, and a few other deities, by the religious sects of the Hindus of the present day. Each sect maintains that the god which it worships unites in his person all the attributes of the deity. The exclusive worshippers of *Vishnu*, *Siva*, &c., must not be confounded with the orthodox worshippers of these deities. Few Brahmans of learning will acknowledge themselves to belong to any of the popular divisions of the Hindu faith; they acknowledge the Vedas, Puranas, and Tantras as the only orthodox ritual, and regard all practices not derived from these sources as irregular and profane. Some of these sects appear to have arisen in great measure in opposition to the Brahmanical order; their teachers are frequently chosen from the lower castes, and the distinction of caste is in a great measure lost in the similarity of schism. (Wilson, 'On the Religious Sects of the Hindus,' in 'Asiatic Researches,' vol. xvi.)

A belief in the transmigration of souls forms an important tenet in the Hindu faith. It is the great object of Hindu worship to obtain a state of future existence, which is supposed to be effected by a reunion of the spiritual nature of man with that primitive spirit which pervades all nature, and which receives the souls of men, when they have been purified, into its essence. The prevailing notion of the means by which an individual may accomplish this object is, by subjecting the body to sufferings and privations, and withdrawing from all intercourse with mankind.

The Hindus have various philosophical systems which they consider to be orthodox, that is, in accordance with the theology and metaphysics of the Vedas; and others which are deemed heretical, as incompatible with the doctrines of their holy books. The professed design of all these schools is 'to teach the means by which eternal beatitude may be attained after death, if not before it.'

An account of the philosophical tenets of the Hindu sects is given by Mr. Colebrooke in his essay 'On the Philosophy of the Hindus,' in the 'Transactions of the Royal Asiatic Society,' vol. i., pp. 19-43; pp. 92-118; pp. 349-361; vol. ii., pp. 1-39; reprinted in his 'Miscellaneous Essays,' vol. i., pp. 227-325. See also Kennedy on the 'Vedanta System,' in the third volume of the 'Transactions of the Royal Asiatic Society.' [BUDDHISM.]

Arithmetic, Algebra, and Astronomy.—The reader is referred to the articles ALGEBRA; ARITHMETIC; ASTRONOMY; and VIGA GANITA, in this work.

Medicine.—Professor Wilson remarks that there is reason to conclude, from the imperfect opportunities of investigation we possess, that in medicine, as in astronomy and metaphysics, the Hindus once kept pace with the most enlightened nations of the world, and that they attained as thorough a proficiency in medicine and surgery as any people whose acquisitions are recorded, and as indeed was practicable, before anatomy was made known to us by the discoveries of modern times. It might easily be supposed that their patient attention and natural shrewdness would render the Hindus excellent observers, whilst the extent and fertility of their native country would furnish them with many valuable drugs and medicaments.

A variety of medical treatises were translated from the Sanskrit into Persian and Arabic; and there is reason to believe that the Arabs derived their principal knowledge of surgery and medicine from the Hindus.

Manufacture and Arts.—It is evident from the most ancient Sanskrit works, as well as from the testimony of the Greeks who visited the country, that the useful and fine arts had attained a considerable degree of perfection among the Hindus in very early times.

Hindustan has always been distinguished for the number and excellence of the substances which it contains for dyeing colours; and the beauty and brilliancy, as well as durability, of the colours were as celebrated among the Greeks and Romans as among ourselves.

In painting the Hindus have not attained much proficiency: their artists draw with great accuracy, but they have no knowledge of perspective. With regard to music, their instruments are numerous;

but their compositions are confined to a few simple melodies, 'many of which possess,' according to Sir W. Ouseley, 'the plaintive simplicity of the Scotch and Irish, and others a wild originality pleasing beyond description. Counterpoint seems not to have entered at any time into the system of Indian music.' The Hindus lay claim to the invention of the game of chess.

In the International Exhibition held at London in 1862, splendid specimens of Hindu workmanship were displayed. Fine woven fabrics, magnificent tapestry, rich embroideries and brocades, carpets of exquisite colours, gold and silver ornaments, inlaid work, carved furniture, and numerous other choice articles, testified to the patient industry and skill of the Hindus. Their tools are, however, of the rudest description, and the arts and manufactures have made but little progress for the last thousand years.

Architecture.—The architecture of the Hindus has hitherto been little studied by professional men. In the absence of plans, elevations, sections, and other details, it will be useful to call attention to some of the resemblances and distinctions existing between Hindu and Egyptian architecture. If there existed no other resemblance between the architecture of the two regions, there would be a decidedly strong one in their hypogæa, or subterranean cavern-structures hewn out of the solid rock. Of these works of exstruction, as they may be called, whose antiquity, at the most moderate computation, extends to several centuries before the Christian era, the most remarkable are those on the island of Elephanta, near Bombay; at Kennerly in that of Salsette; those at Elora, near Dowletabad; and those at Carlee, not far from Poonah. [ELEPHANTA; POONAH; SALSETTE.] Many of those excavations are of prodigious extent, being composed of a series of apartments and recesses cut out of the rock, amounting in some instances to an almost incredible number. While colossal statues and sculptures display themselves within these cavern-temples and on their walls, elaborate embellishments of detail are frequently given to the columns, which appear capriciously put together, it being impossible to determine where their pedestals terminate and their shafts commence, or how much of the shafts belong to the capitals. In this respect the Hindu style, at least this earliest class of it, differs materially from that of the Egyptians, where the shafts have no pedestals, and scarcely anything like a distinct base, but where the capital is plainly distinguishable from the rest of the column.

It is difficult to form any sort of classification, either architectural or chronological, of these excavated temples; but there is one obvious distinction, that in some of them the ceiling is quite flat, as at Elephanta; in others hollowed out, so as to resemble more or less a regular vaulting, as in the temple-cave of Kennerly, in Salsette, and that at Carlee, near Poonah. The ground-plan of an arched temple of Buddha at Elora is exactly similar. Afterwards this form of roof appears to have been elaborated with great industry and skill, for that of the Temple of Mahadéva at Nadone exhibits a perfect model of the most ancient style of dome in the East, and is probably anterior to anything of the kind in Roman architecture. The stones are placed so as gradually

to project one beyond the other, the apex being closed by a circular key-stone. The principle, therefore, is that of a horizontal instead of a radiating pressure, and the edges of all these pressures being rounded off, the spectator sees, on looking up, a vault composed of gradually diminishing circles or annular courses of masonry.

In this respect, then, even the earlier Hindu style presents a marked difference from that of the Egyptians, whose edifices are all covered with flat horizontal ceilings. On the other hand, the affinity between the architectural taste of the two peoples is strongly marked by the prevalent use of colossal statues placed against piers or walls; by the use of caryatid figures, or such as serve as columns; by the general disposition of the sacred buildings; and by the profusion of inscriptions and symbolic sculptures on the walls.

On examining the Hindu works of construction, or edifices erected above ground, we can hardly avoid being struck by the prevalence of pyramidal masses and forms, as exhibited in pagodas or towers. The Egyptian structures of this kind bear a much closer resemblance to natural or rudely constructed prototypes than do those of the Hindus. The gopuras,

Pagoda at Tanjore.

or pagoda towers erected over the gateways leading to temples, are indeed pyramidal in their general form, but infinitely more complex than, not the pyramid alone, but anything else we meet with in Egyptian architecture. Neither do they terminate in a point or mere platform, but have generally a great deal of ornament bestowed on their summit, which sometimes assumes, not inelegantly, the form of a crown. Besides this, they differ from the pyramid in being of far loftier proportions. Of a domical termination, if not exactly a dome, we have an example in the great pagoda at Tanjore, which is considered one of the finest specimens of the kind in India.

There is another class of Hindu monuments,

namely, the temples erected by the Jains, or chief sect of the Buddhists. Some of these were erected long prior to the Christian era, and are distinguished alike by chasteness and beauty of design, and by rich and exquisite finishing. (Ferguson's *Hand-book of Architecture*.)

HINGE, a kind of joint, upon which doors, gates, shutters, box-covers, &c., are made to turn in the act of opening and shutting. Hinges are constructed in a great variety of forms; but in most of the commoner kinds the action is that of a hollow cylinder working round a fixed central pin. In Collinge's patent hinges, which are peculiarly adapted for hanging large heavy doors and gates, the principal rubbing action is between a hollow cap and an accurately turned sphere, formed, as it were, upon the end of the pin, a cavity being provided for the reception of a supply of oil to lubricate the rubbing surfaces. Redmund's rising hinges are frequently used for hanging room-doors in houses of superior character. In ordinary door-hinges the hollow cylinder which works round the axis or central pin is divided transversely into two or more portions; but in the rising hinges, instead of the hollow cylinder being divided transversely at right angles, it is divided by spiral or rather helical lines. The result of this contrivance is, that when the door is opened it is lifted up a little from the floor by the sliding upon one another of the inclined helical surfaces; so that, although the door may shut very close to the floor, it rises when opened to a sufficient height above the floor to allow its lower edge to clear the carpet. Other forms of hinges are very numerous, and of late years there has been a revival of the elaborately ornamented mediæval hinges, in connection with Gothic architecture.

HINNITES. M. DeFrance gave this name to a few fossil species of *Conchifera monomyaria*, which occur in supracretaceous strata; one (*H. Dubuissonii* of Sowerby) is found in the English crag.

HINNY, a word derived from the Latin, *Hinnio*, 'I neigh,' and used to designate the produce of the horse and a she-ass, as the word *mule* does the hybrid of the he-ass and the mare.

HIP. [SKELETON.]

HIPPA, HIPPA TRIBE, *Hippides* of Latreille, *Hippians* of M. Milne-Edwards, the latter of whom thus describes these crustaceans belonging to his family of *Pterygura*:—The tribe is composed of a limited number of small anomourous crustaceans, which appear to be especially framed for burrowing in the sand, and which present extraordinary forms. The carapace is longer than it is wide, and very convex transversely, presenting always on each side a great lamellar prolongation, which more or less covers the base of the feet; it is truncated posteriorly, and appears to be continuous with the anterior portion of the abdomen, which is very wide and lamellar laterally. One of the pair of antennæ is always very long. The external jaw-feet do not present a conformation like that which is observable in the greater part of the crustaceans treated of in the prior part of M. Edwards' system; they have neither flagrum (fouet) nor palp, and their last three joints are very well developed. The sternum is linear, and the feet are imperfectly extensible; those of the first pair are monodactylous or subcheliform, and those of the two or three succeeding pairs are

terminated by a lamellar joint proper for burrowing. The posterior feet are filiform, semi-membranous, recurved forward, and hidden between the lateral parts of the carapace and base of the preceding feet. The penultimate ring of the abdomen is always furnished with a pair of false feet, terminated by two more or less oval ciliated blades or laminae; but these appendages have a forward curvature, and are not applied against the seventh segment so as to form with a fan-shaped caudal fin, as in the *Macrura*. The vulvæ are on the first joint of the third pair of feet. The branchiæ are disposed on a single line, and inserted by a peduncle which rises near the lower third of their internal surface. This tribe is divided into three genera, *Remipes*, *Albunea*, and *Hippa*.

As examples we may mention *Remipes testudinarius*; length of carapace 15 lines; locality, the coast of New Holland. *Albunea Symnista*; length of carapace 10 lines; locality, the seas of Asia. *Hippa emerita*; length from 1 inch to 15 lines; locality, the coasts of Brazil.

HIPPA'LIMUS, a genus of zoophyta proposed by Lamouroux. Goldfuss supposes that it may be included in his genus *Scyphia*. It is fungiform and pediculated, with pores on the upper surface only, and a deep central pit. From the blue marls of the department of Calvados.

HIPPARCHUS, the first astronomer on record who really made systematic observations, and left behind him a digested body of astronomical science. He was born, according to Strabo, at Nicæa in Bithynia, and was alive, as appears from his observations preserved by Ptolemæus, in the interval 160–125 B.C.; but neither the year of his birth nor that of his death is recorded. His astronomical observations were probably commenced in Bithynia, and certainly continued at Rhodes; whence he is called by some authors the Bithynian, and by others the Rhodian, and some even suppose two astronomers of the same name, which is certainly incorrect.

The writings attributed to Hipparchus are all lost except a commentary on Aratus, written probably when he was young, since he does not mention any of his subsequent discoveries, and the results of observation are not so correct as those of his catalogue.

The following summary is from the preface to Delambre's 'History of Ancient Astronomy,' in which work will be found the most complete account of the labours of Hipparchus. The bias of this historian seems to be, to add to Hipparchus some of the fame which has been generally considered due to Ptolemæus, for which he gives forcible reasons. 'Let no one be surprised at the errors of half a degree which we attribute to Hipparchus, seemingly with reproach. It must be remembered that his astrolabe was nothing but an armillary sphere, of no great diameter, and with very small subdivisions of a degree, as well as that he had neither telescope, vernier, nor micrometer. What should we do even now if deprived of these helps, and if we knew neither the refraction nor the true altitude of the pole, on which point, even at Alexandria, and with armillæ of every sort, an error of a quarter of a degree was committed? At this day we dispute about a fraction of a second; they could not then answer for any fraction of a degree, and might be wrong by a whole diameter of the sun or moon. Let

us rather think of the essential services which Hipparchus rendered to astronomy, of which science he is the true founder. He was the first who gave and demonstrated methods of solving all triangles, whether plane or spherical. He constructed a table of chords, of which he made nearly the same use as we now do of our tables of sines. He made many more and much better observations than his predecessors. He established the theory of the sun in such a manner that Ptolemæus, 263 years afterwards, found nothing to change. It is true that he mistook the inequality of the sun's motion: but it can be shown that his mistake arose from an error of half a day in the time of the solstice. He himself avows that he may have been wrong by a quarter of a day; and we may always safely suppose that, without impeachment of an author's integrity, his self-love may halve the error which he is really liable to commit. He determined the first inequality of the moon (the equation of the centre), and Ptolemæus found nothing to change in his result: he gave the mean motion of the moon, and that of the apogee and nodes, in which the corrections made by Ptolemæus were slight, and of more than doubtful goodness. He had a sight of the second inequality (the evection); it was he who made all the observations necessary for a discovery, of which the honour was reserved for Ptolemæus; a discovery which he had not perhaps time to finish, but for which he had prepared everything. He showed that all the hypotheses of his predecessors were insufficient to explain the twofold inequality of the planets; he predicted that none would be successful which did not combine the two hypotheses of the excentric and epicycle. He had not the proper observations, because they require more time than the duration of the longest life; but he made them ready for his successors. We owe to his catalogue the important knowledge of the retrograde motion of the equinoctial points. We might, it is true, have derived this knowledge from much better observations, made within the last hundred years; but we should then have had no proof that this motion remains sensibly the same through a long course of ages; and the observations of Hipparchus, by their number and their antiquity, and in spite of the errors which we are obliged to admit, give important confirmation to one of the fundamental points of astronomy. It is to him that we owe the first discovery of this phenomenon. He also invented the planisphere, or the method of describing the starry heavens upon a plane, and of deducing the solution of problems in spherical astronomy by a method often more exact and convenient than that of the globe itself. He is also the father of real geography, through the happy idea of marking the position of towns in the same manner as that of the stars, by circles drawn through the pole perpendicularly to the equator, that is, by latitudes and longitudes. His method, by means of eclipses, was for a long time the only one by which the longitude could be determined; and it is by means of the projection of which he was the author that we now make our maps of the world and our best geographical maps.

HIPPELAPH, an animal of the deer kind, in Norway, about the size of the elk, and partaking of the nature of the horse and the stag.

HIPPIAS. [PISISTRATUS.]

HIPPOBOS/CIDÆ (Gr. *hippos*, 'a horse,' and *bosco*, 'to feed'), a family of dipterous, viviparous insects, the type of the family being the *Hippobosca*, or Horse-fly. They are generally known by the name of Forest-flies, the young of which undergo their first metamorphosis in the womb of their parent, and are brought forth in the pupa state.

HIPPOBRO'MA, a genus of plants belonging to the natural order *Lobeliaceæ*. *H. longiflora* is the only species. It is a native of Jamaica, St. Domingo, Cuba, and Martinique, in damp places and by the side of streams. This is one of the most poisonous of plants. If the juice only accidentally touches the lips or eyes, it produces a burning inflammation.

HIPPOCAMPUS. A genus of pipe fishes of singular construction and peculiar habits; the upper parts having some resemblance to the head and neck of a horse in miniature, which has suggested the English name sea-horse. When swimming they maintain a vertical position.

HIPPOCASTANÆÆ, (from *hippocastaneum*, the specific name of the horse-chestnut), a subdivision of the order *Sapindaceæ*.

HIPPOCRATEA, a genus of the natural family of *Hippocrateaceæ*, so named after Hippocrates, and which might therefore be expected to contain many useful or medicinal plants. But it is not so. The species consist of moderate-sized trees, which are found in the hot parts of the world, as in the tropical parts of America, in Sierra Leone, the warmer parts of India, and the island of Timor.

HIPPOCRATEA'CEÆ, a small natural order of exogenous plants. The species are woody, and often climbers; they inhabit Africa, the Mauritius, and the tropical parts of America. In general they are of no importance for economical or medical purposes. One species bears an eatable fruit, and another has oily seeds with sweet taste.

HIPPOCRATES was born at Cos, B.C. 460. His family followed the pursuit of medicine for near three hundred years, and produced seven physicians, who attained considerable celebrity, and who are supposed to have written the numerous treatises which are commonly attributed to Hippocrates alone. Before their time the knowledge of medicine was either confined to the priests, who employed their skill in maintaining their influence over the people, and carefully concealed the little knowledge they possessed, or was merely followed as a subordinate pursuit by the philosophers of the day. It is to the Asclepiadæ that the science of medicine is indebted for a separate existence, and the great progress which it made in their hands after this separation sufficiently proves the wisdom of their proceeding.

The most celebrated of the family was the subject of the present notice, Hippocrates, the son of Heraclides and Phænarete, who is supposed to have been the author of this important revolution in medicine. His medical studies were pursued under the superintendence of his father and of Herodicus; and he is said to have had for his masters in philosophy Gorgias of Leontini, the celebrated sophist, and Democritus of Abdera, whose cure he afterwards effected. We are told that he spent some time at the court of Perdiccas, king of Macedonia, and visited Thrace and Scythia; and it is probable that these statements are

true, as mention is made in his writings of several towns in Thrace. (Suidas, *Ἰπποκράτης*.)

The principles of Hippocrates were those of rational empiricism. He did not attempt to form his theories from *à priori* reasoning, but he observed the phenomena of nature, and deduced from them such conclusions as these phenomena would justify. That he adhered to this principle in all cases, however, is not to be supposed. He taught that the body is composed of four primary elements—fire, water, earth, and air; that these elements, variously combined, produce the four cardinal humours, and these again the different organs of the body. These doctrines are principally developed in the treatise 'On the Nature of Man.' His knowledge of anatomy seems to have been very limited. The superstitious respect which was paid to the remains of the dead among the Greeks, prevented him from acquiring any knowledge on this subject by dissection of the human body. He gives such descriptions of the bones as show that he had indeed studied the subject, but not acquired any very accurate knowledge. In his pathology he confines himself principally to the investigation of the remote causes of diseases, without entering into any speculations on their nature. However, he explains inflammation by the passage of blood into those parts which did not previously contain it. He paid great attention to the effects of changes in the external conditions of life, namely, air, warmth, moisture, food, upon its phenomena, and those of disease. He recommended that particular attention should be paid to the state of the seasons.

Among the doctrines of Hippocrates, that of critical days, upon which he supposed the evacuation of the morbid matter when concocted to take place, is the most remarkable. Of the indications to be drawn from examination of the pulse Hippocrates was not aware, and the word *sphygmus* (*σφυγμῖς*) is usually employed by him to denote some violent pulsation only. We must not forget that Hippocrates asserts that auscultation may be employed to distinguish between the presence of pus and serous fluid in the cavity of the pleura. The statement is in itself incorrect, but the fact of his having actually practised auscultation is no less interesting.

Hippocrates appears also to have introduced some valuable improvements in the treatment of disease. In fevers and acute diseases he confined his patients to a liquid diet, but not so strictly as some other physicians, whom he charges with starving their patients to death. In his general treatment he employed purgatives, some of which were of the most violent character, as the black and white hellebore and elaterium, which generally produce excessive vomiting at the same time. He mixed up a little theory with his treatment; for he would not allow purgatives to be employed unless the humours were duly concocted. To relieve the head in certain diseases he was accustomed to make use of sternutatories. In acute affections, when the disease was violent, he employed bleeding, and recommended that blood should be taken from as near the affected part as possible. This was the origin of the doctrine which recommended bleeding in pleurisy from the arm on the side affected. He also made use of cupping glasses, with and without scarification. Certain

diuretic and sudorific medicines also entered into his pharmacopœia, and he was not ignorant of the virtues of the poppy.

In the time of Hippocrates the distinction between medicine and surgery had not been made, as we find among the works usually attributed to him in the list of Erotian, treatises on fractures, on ulcers, and on wounds of the head.

It appears that consultations were not unknown in the time of Hippocrates, for in the latter part of the 'Præcepts' he says that a physician ought not to be ashamed to call in the assistance of another, if he finds himself at a loss in the treatment of his patient. The oath which he administered to his pupils shows the high sense he had of the duties and responsibilities of a physician. The pupil is made to swear 'that he will reverence his teacher as a father, and his descendants as brethren; that he will use his art to the benefit of his patients, and never to their injury or death, even if requested by them; that he will never attempt to procure abortion, that he will be chaste, and never divulge any professional secrets.' Hippocrates wrote in the Ionic dialect, though the island in which he was born was originally colonized by the Dorians. His style is remarkably concise, so as to render his meaning at times somewhat obscure, and it would appear that he occasionally makes his statements too general, in order to avoid loading his writings with exceptions. The high estimation in which his works have been held is proved as well by the general reputation of his name, as more especially by the numerous commentaries on them which have been published in all ages. His knowledge of anatomy and physiology, and of the processes which go on in the body during health and disease, was extremely deficient; but in the accuracy with which he observed the symptoms of disease, and in the fidelity of his descriptions, he has rarely, if ever, been surpassed. It is upon these grounds that he has justly obtained the title of 'the Father of Medicine,' and will at all times continue to command the respect of his medical descendants.—(Sprenghel, *Histoire de la Médecine*, tome i.)

HIPPOCREPIS, a genus of plants belonging to the natural order *Leguminosæ* and tribe *Hedysarææ*. *H. Balearica*, Minorca Horse-shoe Vetch, is a native of the island of Minorca. It is a very pretty plant, worthy of cultivation, but requires the greenhouse in winter. *H. comosa*, common Horse-shoe Vetch, is a native of Europe, and is found on dry chalky banks in Great Britain. It is also found in the north of Africa.

There are seven or eight more species of Horse-shoe Vetch. They are all worth cultivation on account of their beauty.

HIPPODROME (Gr. *hippos*, 'a horse,' and *dromos*, 'a race-course'), a large inclosed space set apart by the ancient Greeks for their horse and chariot races. There appears to have been little substantial difference between the Greek hippodrome and the Roman circus, except that, from the Romans not having been accustomed to allow more than four chariots to compete at once, the circus was made much narrower than the hippodrome. Bearing this distinction in mind, and that the number of chariots which ran necessitated a more complicated arrangement of the *carceres*—they being placed along a line formed like

the prow of a ship, with the apex towards the area, and each of the sides 400 feet long—a sufficiently clear conception of the form and character of the hippodrome will be obtained by a reference to the article CIRCUS.

The term hippodrome has been given to a circus constructed at Paris in 1845, and also to a large field used for a race-course in the plain of Longchamp near Boulogne.

HIPPOLYTE-DU-FORT. [GARD.]

HIPPOLYTUS, a bishop and ecclesiastical writer of the third century, whose name has acquired importance in connection with a recently discovered treatise, edited, with explanations and dissertations, by Chevalier Bunsen. The discovery of this treatise was somewhat remarkable. It was found among various other MSS. brought from Mount Athos to Paris in 1842, and deposited in the royal library there. It was designated as a 'Book on all the Heresies,' but without any author's name. M. Emmanuel Miller, a functionary of the institution, was attracted to it by some fragments of Pindar that it contained. On examining it he formed the conclusion that it was a lost production of Origen; and under this impression the Oxford University press agreed to publish it. It appeared in 1851. It was soon after its publication carefully studied by Bunsen; and the conclusion at which he arrived regarding it was that it was a genuine production of the third century, but that its author was not Origen, but Hippolytus. Various scholars—Dr. Duncker and Dr. Jacobi in Germany, and Dr. Wordsworth in England—have confirmed this conclusion. The character and position of Hippolytus have become much better known than before, in connection with the inquiry excited by the recovery of this treatise. He was a Roman ecclesiastic and bishop of Portus, the harbour of Rome on the northern bank of the Tiber, lying opposite to the ancient Ostia. In the third century this appears to have been a place of some commercial importance, and of considerable population. The great metropolis of the world brought ships from all maritime countries into its harbour, and especially many Greek sailors and merchants. Among this trading Greek population Hippolytus lived and laboured. A Roman ecclesiastic, he was yet Greek in speech and Greek in his mode of thought. He was a disciple of Irenæus, bishop of Lyons, who again was a disciple of Polycarp of Smyrna, who had seen and conversed with the apostle John. While occupying an independent position in his own bishopric, he was directly connected with the Roman church as a member of its presbyterial council. In the ninth book of the recovered treatise on Heresies, Hippolytus gives us a somewhat lively account of the religious and ecclesiastical state of Rome in the middle of the third century. According to this account it by no means presented the picture of unity which many would fain attribute to the early Roman church. Two of the Roman bishops, Zephyrinus and Callistus, are accused of favouring the heresy of Nœtus—a kind of early unitarianism; and it is evident, moreover, that various scandals were abroad as to the latter of these bishops. Hippolytus appears as an earnest and energetic churchman and defender of the faith. The pupil of Irenæus, he was the friend and precursor of Origen in the

speculative and critical study of Christian doctrine, and in oratorical talent. In his 'Refutation' of the heresies of his day he shows an enlightened acquaintance with the course of Grecian speculation, as well as with the meaning and application of scripture. He was, according to Bunsen, one of the first preachers in the Roman church. Before his time preaching had been merely a popular exposition of the Gospel of the day. He enlarged this exposition into the formal homiletic address, in which he treated of Christian topics in an elaborate and scientific manner.

HIPPO'MANE MANCANILLA, the Manchineel-tree, is a tree of very considerable size, and of a handsome aspect, belonging to the natural order *Euphorbiaceæ*, and among the most poisonous of all known vegetable productions. When the fruit is ripe, it is a fleshy yellowish-green round body, very like a European crab-apple. The tree is common in the West India Islands, although pains have been taken to extirpate it. In some places it forms thick woods, as upon Sandy Island, near Tortola. The whole plant abounds in a milky juice of the most venomous description. Dropped on the skin, it produces a sensation of severe burning, followed by a blister; and the fruit, when bitten, causes dangerous inflammation of the mouth. According to Sir Robert Schomburgk, it is dangerous to sleep beneath the tree, and rain passing through the branches blisters the skin of a person below them. The wood of this tree is represented to be of fine quality, handsome, and well suited for cabinet-makers' purposes.

HIPPO'NYX (Gr. *hippos*, 'a horse,' and *onyx*, 'a claw'), a genus of Limpets, of the tribe *Scutibranchia*, in which the shell is patelliform.

HIPPO'PHAE, a genus of plants belonging to the natural order *Elaeagineæ*. The only species of this genus is the *H. rhamnoïdes*, which is a small shrub found on the east and south-east coasts of Great Britain, and other parts of Europe. The acid berries yielded by this plant are often eaten as a salad both in this country and in France. This plant also yields a colouring matter, which is used for dyeing yellow. Although in this country the berries are innocuous, they seem to exert a deleterious influence, or are supposed to do so, in some of the countries of the south of Europe.

HIPPOPOTAMUS, the Roman name for the River Horse, and retained by modern zoologists as the generic appellation of a limited group of bulky pachydermatous animals, restricted in the present day, as far as we know, to Africa.

'The Hippopotami,' says Cuvier, 'have four toes on each foot, nearly equal, and defended by small hoofs; six grinders on each side above and below, of which the first three are conical, the posterior three crowned with two pairs of bold elevations, which wear down by attrition, when the form of a trefoil is exhibited on their crowns; four incisors in each jaw, of which the uppermost are short, conical, and recurved, the inferior are long, cylindrical, pointed, and directed obliquely forwards; one canine on each side above and below; the superior is straight, the inferior very massive and recurved, both wearing themselves by attrition against each other. These animals have the body very massive, destitute of hair, the limbs very short, the belly almost dragging

on the earth, the head enormous, terminated by a large swollen muzzle which covers the array of their huge anterior teeth. The tail is short, the eyes and the ears small. The stomach is divided into several sacculi. They tenant rivers, feeding on roots and other vegetable matters, and display much ferocity and stupidity.'

Elsewhere Cuvier remarks that there is no animal that requires to be more studied at different ages than the hippopotamus, in order to acquire a perfect knowledge of the molar teeth, which change their form, their number, and their position: and, in his 'Ossemens Fossiles,' he goes into minute details of their changes.

When Cuvier wrote, only one living species of hippopotamus was known. M. Desmoulins, however, from examination of skulls and bones from South Africa and from Senegal, has demonstrated that there are certainly two, which are respectively designated *H. Capensis* and *H. Senegalensis*. Moreover, he suggests that the hippopotamus of the Nile may possibly be distinct from either of these. Be this as it may, in habits, manners, and form the Hippopotami of all parts of Africa agree with each other. They inhabit the banks and beds of the larger rivers and the inland lakes of Africa, from the Gariep to the upper Nile and its tributary branches. It is not, however, exclusively restricted to fresh waters, for it is marine as well as fluvial; and Dr. Smith thinks it difficult to decide whether it gives preference to the river or the sea for its abode during the day. When the opportunity of choosing the river or the sea existed, he found that some selected the one and some the other.

Hippopotamus.

The hippopotamus is little inferior in bulk to the elephant, though lower in stature, owing to the shortness of its thick pillar-like legs. The head is ponderous, and the great thick lips are studded with wire-like bristles. The mouth is wide; the nostrils open on the top of the swollen muzzle; and the small eyes are situated high on the head; hence by raising only a small section of the head above the surface of the water, the animal can breathe and look around, the body remaining submerged. The hide is of immense thickness, being upwards of two inches deep on the back and sides; it is extremely dense, and is manufactured by the natives of various districts, both of northern and southern Africa, into shields, whips or scourges, and other articles. Be-

tween the skin and the flesh a layer of fat intervenes, which is salted and eaten as a delicacy by the Dutch colonists of South Africa, by whom it is termed Sea Cow's Speck (bacon). The flesh also is said to be excellent.

The general colour of the hippopotamus is dusky brownish-red, passing on the sides and limbs into a light purple red or brown; the under parts, the lips, and the eyelids are light wood-brown, with a tinge of flesh colour; the hinder quarters are freckled with spots of dusky brown. The hairs which fringe the tail and ears are black, the bristles on the muzzle yellowish-brown. The male considerably exceeds the female in size. The period of gestation is not ascertained. A single young one only is produced at a birth.

The hippopotamus is to a great extent nocturnal in its habits; during the day it remains under its fluid canopy, rising every five or six minutes for the purpose of respiration. At night it comes on land to feed, at least in districts fully inhabited by man, and often travels to a considerable distance in quest of some favourite diet. It visits the plantations of grain, trampling down as much as it consumes, and doing great damage. Burckhardt states that in Dongola it is a dreadful scourge to the inhabitants, who lack the means of destroying it. The hippopotamus is wary, and indisposed to act on the offensive, yet, in districts where the sound of a musket is seldom heard, it shows but little fear of man. When attacked and wounded, the hippopotamus becomes exceedingly furious, and, if on land, rushes opea-mouthed on its aggressor. But the danger from the vengeance of this animal to boats and their crew on the water is far greater.

We need not attempt a laboured exposition to prove that the hippopotamus was known to the ancients, although it may be admitted that some of the descriptions of the older writers, as Herodotus, Aristotle, Diodorus, and others, are more or less incorrect. Scarus, during his ædileship, exhibited one of these animals at Rome. Augustus exhibited one on his triumph over Cleopatra, and at subsequent periods under the later emperors they were introduced into the Roman amphitheatre. Commodus showed five on one occasion. The hippopotamus is very tolerably delineated on the Prænestine Pavement.

Fossil Hippopotami.—The remains of fossil hippopotami occur abundantly in the tertiary series. They are most common in the pliocene period of Lyell, and are frequently met with in the superficial beds of gravel, clay, and sand, termed by some diluvial, in the ossiferous caverns, osseous breccia, &c. They are also found in some of the beds of the miocene period.

HIPPURIC ACID, an acid obtained from the urine of cows and horses, and somewhat analogous in character to benzoic acid. Its composition is $C^{20}H^9O^6N^1$. Its combinations with other bodies have not been extensively examined.

HIPPURIS, a genus of plants belonging to the natural order *Haloragææ*. Three species of this genus have been described. Of these, *H. vulgaris*, the common Mare's Tail, is found abundantly throughout Europe and North America. It is found in ditches and lakes, and is very common in Great Britain in stagnant waters and slow streams.

HIPPURITES, in Zoology, a name given by

Knorr and Schroeter to a fossil coral (*Cyathophyl-
lum ceratites*, Goldfuss) of the Eifel transition lime-
stone. Guettard also used this title for a lamelliferous
coral. By Lamarck, Defrance, and other writers, this
name is given to a somewhat problematical group of
fossils found in limestones of the oolitic age which
flank the Alps in the Untersberg, near Salzburg, at
Regensburg, &c., in the chalk of Perigord, Alet, &c.
Lamarck places Hippurites with Belemnites and
Orthoceratites, among the Cephalopoda. Latreille
takes nearly the same view. Rang introduces the
genus among the *acephalous Rudista* (singular bivalve
shells), according to the views of De Blainville.

HIPTAGE, a genus of plants of the family of
Malpighiaceae, better known by the name *Gertnera*.
The genus contains only two species: one, *H. Mada-
blota*, which is common in the forests of many parts
of India; the other, *H. obtusifolia*, is found in China,
but commonly cultivated as an ornamental plant in
India.

HIRCIC ACID, obtained from goat's fat, is a
liquid at a temperature of 32°: it is lighter than
water, smells of the goat, is insoluble in water, and
forms soluble salts with potash and barytes.

HIRCIN, a principle similar to butyrine, which
exists in goat's fat and in mutton suet, combined
with olein.

HIRE, LA. [LAHIRE.]

HIRING, is the contract by which property or
labour is employed for a limited time for some con-
sideration or reward. For full information on the
various kinds of hiring the reader is referred to the
articles CARRIER, LODGINGS, SERVANTS, SHIPS,
TENANT and LANDLORD.

HIRUDINE (Lat. *hirudo*, 'a leech'), a family
of *apodous anelides*, of which the *Hirudo* is the type.

HIRUNDINIDÆ. [SWALLOWS.]

HISINGERITE, a mineral of a dull black colour,
found in Sweden, and so called in honour of Hising-
er, who first analyzed it. It has an earthy fracture,
capable of being cut with a knife. Its specific
gravity is 3.04; and its constituent parts are—proto-
xide of iron, 47.80; silica, 27.50; alumina, 5.50;
oxide of manganese, 0.77; water, 11.75.

HISPANIA. [SPAIN.]

HISPANIA/LA, *Hispaniola, Española* (i.e., Little
Spain), known also under the names of SAINT
DOMINGO and HAYTI, is one of the Great Antilles,
or larger islands of the West Indies. It extends from
68° 30' to 74° 30' W. long. Its length is about
360 miles. It lies between 18° and 20° N. lat.; but
a promontory on the southern coast projects about
20' beyond 18° N. lat. The area is 28,000 square
miles, being somewhat less than that of Scotland.

Hispaniola is the most fertile island in the West
Indies. Its surface exhibits a great variety on rather
a large scale. Near the centre of the island there is
a mountain-knot, called Cibao, whose elevation does
not fall short of 8000 feet. Ranges of mountains,
which rise from 2000 to 5000 feet, occupy the greater
part of the island, but contain between them exten-
sive valleys and plains. In the eastern part of the
northern plain are extensive savannahs, or natural
meadows; but towards the west the soil is fruitful.
At the eastern extremity is the lake called Laguna
de Henriquillo, which is fifty miles in circuit. The
country is watered by numerous rivers.

The coast, which is about 1200 miles in length,
has a great number of harbours, some of which are
spacious, deep, and safe. Near Cape St. Nicolas is
the port of St. Nicolas, which is six miles long, and
capable of holding a large fleet. The harbour of the
town of St. Domingo is a very indifferent one.

The climate of Hispaniola (which is very unhealthy
for Europeans) differs considerably from that of the
other Antilles. In July begin the abundant rains
on the south coast, which continue through August,
September, and October. The winter is rather cool,
the thermometer rarely exceeding 70°, and still
more rarely descending below 60°. The northern
coast has only showers during August, September,
and October, but in December and January the rains
descend in torrents: afterwards they are moderate,
and cease entirely in April. The heat of the sum-
mer is moderated by the prevailing northern winds.
Hurricanes are frequent on the southern coast, but
they occur rarely on the northern shores.

In the last century Hispaniola was noted for its
extensive plantations of sugar, coffee, and cotton, but
they are much reduced. The principal commercial
wealth of the island is at present derived from the
forests which cover the greatest part of the moun-
tains. The timber consists chiefly of mahogany-
trees and different kinds of dyewoods.

Gold, silver, copper, tin, iron, and rock-salt are
found in the island; but the mines are now unpro-
ductive.

The exports from Hayti to the United Kingdom
in 1863 were valued at 276,610*l.*, and consisted
chiefly of cotton, coffee, logwood, and mahogany.
The imports from Great Britain in the same year
amounted to 545,192*l.*, of which cotton manufac-
tures figured for 280,609*l.*, and linen manufactures
for 147,045*l.*

The aborigines are now extinct, but a consider-
able part of the present population consists of their
descendants, mixed with the blood of Europeans and
negroes. The number of mulattoes, or descendants
of Europeans and negroes, is still greater; indeed,
they may be considered as constituting the nation.
The population is stated to be 760,000.

Port au Prince, the capital and seat of govern-
ment, is situated between the large plain of Cul de
Sac and a more narrow one extending along the
southern shores of the Bay of Gonaves. The streets
are sufficiently wide and commodious. Its com-
merce with the United States and with Jamaica
is considerable. The population in 1863 was about
21,000. The town is built chiefly of wood, and is
partially fortified. The principal edifices are—the
palace of the state, the church, arsenal, mint, lyceum,
military hospital, and courts of law. The vicinity
is marshy, and the climate unhealthy. The harbour
is a safe one, except during the hurricane months,
from August to November. It is the seat of most
of the foreign trade of the island.

San Domingo, on the southern coast, is the oldest
European establishment in America, having been
founded by Columbus in 1504. The population is
about 15,000. It has a Gothic cathedral, numer-
ous other churches, convents, hospitals, colleges, an
arsenal, lighthouse, and barracks. The harbour is
unfit for large ships.

The Roman Catholic is the established religion of

Hayti, but all others are tolerated. The army consists of about 50,000 men; and the public revenue averages about 5,000,000 francs annually, the expenditure being 500,000 francs in excess of that amount. Some years ago education and civilization were at a very low ebb, but many schools have been recently established.

Hispaniola was discovered by Columbus, and was possessed by Spain until 1697, when the western part of it was ceded to France. In 1794 the negro slaves were declared free by the French National Convention, and shortly afterwards they rose against their European governors, under Toussaint L'Ouverture, Dessalines, and Christophe, and at length succeeded in establishing a monarchy in the northern parts under Christophe, and a republic in the western under Petion. The struggle was one of the most vindictive in history—nearly the whole of the European population having been exterminated. On the death of Christophe (who killed himself during an insurrection) in 1820, the whole became united into one republic, and so continued for many years, although in a frequently disturbed state. In 1844 the inhabitants of the eastern or Spanish part of the island rose against their Haytian oppressors, and formed themselves into a republic, which was recognized by France in 1848, and Great Britain in 1850. In March, 1861, they voluntarily re-united themselves to Spain; and since that time various attempts have been made to again bring the whole island under the dominion of Spain. The western portion of the island was proclaimed an empire in 1849, but the republican form of government was re-adopted in 1859.

HISPIDÆ (Lat. *hispidus*, 'bristly'), a family of Coleopterous insects, of the tribe *Monilicornes*.

HISTERIDÆ (Lat. *histrion*, 'an actor'), a family of Coleopterous insects, of the tribe *Lamellicornes*.

HISTIOPHORUS (Gr. *histon*, 'a sail,' and *phoreo*, 'to bear'), a genus of sword-fishes, of the family *Scomberidæ*, and sub-family *Xiphianæ*.

HISTOLOGY (Gr. *histos*, 'a tissue'; *logos*, 'a discourse'), the name given to the doctrine of the tissues which make up the different organs of the animal frame. Professor Schwann classifies the fundamental tissues of the human body as follows:—

1. *Simple membrane*. Examples: walls of cells, capsule of lens of the eye, &c. 2. *Fibrous tissue*. Examples: white and yellow fibrous tissue, elastic tissue, &c. 3. *Cellular tissue*. Examples: cartilage, fat, gray nerve-matter, &c. 4. *Sclerous or hard tissue*. Examples: bone, teeth, &c. 5. *Compound membranes*. Examples: mucous membrane, skin, synovial membranes, &c. 6. *Compound tissue*. Examples: nerves, muscles, and fibro-cartilage. These, and the many subdivisions of each branch, fall to be considered by the histologist.

HISTRIONES, pantomimic actors among the ancient Romans, who were considered as inferior to the performers of the regular drama. Hence was derived the term *histrionic*, as applied to the modern stage.

HITCHCOCK, EDWARD, D.D., LL.D., an American naturalist and theologian, was born at Deerfield, Massachusetts, on the 24th of May, 1793. When only twenty-three years of age he became the head-master of the academy of his native place. A few years afterwards he received ordination, and

became the pastor of a congregation at Conway. He had previously made his debut as an author by the publication of a tragedy 'On the Downfall of Bonaparte.' He now turned his attention to the study of natural history. Acquiring a sound practical knowledge of geology, as the science was at the time understood, he published in 1823 a work on the 'Geology of the Connecticut Valley.' Two years later, the author became professor of chemistry at Amherst College. He prepared, while he held this situation, various papers upon scientific subjects, one of the most valuable of these being a catalogue of the wild plants growing in the neighbourhood of Amherst. He wrote about the same time several treatises of a more popular character. Of these perhaps the most important were 'Dyspepsia Forestalled and Resisted,' and 'An Argument for Early Temperance.' The legislature of Massachusetts had first the merit of ordering a scientific state survey on a great scale. Dr. Hitchcock was placed at the head of the undertaking. He published several reports, giving an account of the explorations made for the government; the most important of them relating to the mineralogical resources of the territory. The earliest of these was published in 1831 under the title of a 'First Report on the Geology, Botany, and Zoology of Massachusetts.' A second report followed under the same title in 1833. The most important of the series did not, however, appear until 1841, when it was published under the title of 'A Final Report on the Geology of Massachusetts,' 2 vols. royal 4to. In 1844 Dr. Hitchcock was chosen president of Amherst College. He conjoined the general superintendence of the institution with the duties of professor of geology and natural theology. Four years later he published 'Fossil Footmarks in the United States.' Between 1845 and 1849 Dr. Hitchcock delivered annually a course of 'Religious Lectures on the Phenomena of the Seasons.' They have since been published. In 1850 he was appointed by the state of Massachusetts agricultural commissioner to visit the principal countries of Europe, with the view of ascertaining what had been done by foreign governments to promote the cultivation of the soil. A year later he published his 'Report on the Agricultural Schools of Europe.' Since this period the works of Dr. Hitchcock have had a close connection with the subjects discussed in the lectures delivered by him at Amherst in his double capacity of professor of geology and natural theology, treating as most of them do of the mutual relations of these two departments of human knowledge. In 1851 he published the most popular of all his works, 'The Religion of Geology and its Connected Sciences.' This work has been frequently republished, several editions having appeared in this country. It was followed in 1853 by 'Outlines of the Geology of the Globe, and of the United States in particular,' in 1857 by 'Religious Truth illustrated from Science,' and in 1855 by an 'Introduction to a New Edition of the Plurality of Worlds.' All these works are marked by great ingenuity of thought, and are written in a graceful and attractive style. They enjoy a well-deserved popularity.

HIVE. [BEE.]

HOADLEY, BENJAMIN, born at Westerham in Kent, in November, 1676, died in April, 1761, was

successively bishop of Bangor, Hereford, Salisbury, and Winchester. He is to be regarded, 1st, as a principal writer among the divines of the English Church who are called Rational, that is, who have renounced the whole of what constitutes proper Calvinism, and have advanced more or less near to the opinions which are comprehended under the term Unitarianism; 2nd, as the great advocate of what are called Low Church principles, a species of Whiggism in ecclesiastics. It was out of a sermon of his upon the text, 'My kingdom is not of this world,' that the celebrated Bangorian controversy arose. A full account of Bishop Hoadley is given in the 'Imperial Dict. of Univ. Biography.' Mackenzie, 1865.

HOADLEY, BENJAMIN, M.D., eldest son of Bishop Hoadley, was born February 10, 1705, in London. He was admitted of Corpus Christi College, Cambridge, April 8, 1722, and received his degree of M.D. in 1729. In June, 1742, he was appointed physician to his majesty's household, and in January, 1746, was also appointed physician to the household of Frederick, prince of Wales. He was the author of 'Three Letters on the Organs of Respiration,' read at the Royal College of Physicians, London, 1737, being the Gulstonian Lectures for that year; 'Oratio Anniversaria in Theatro Col. Medicor. ex Harveii instituta, habita die 18mo Oct., 1742'; 'Observations on a series of Electrical Experiments,' 1756, 4to. Dr. Hoadley is now known chiefly as the author of the comedy of 'The Suspicious Husband,' 1747, in which Garrick was distinguished for his performance of Ranger. Dr. Hoadley died August 10, 1757, in his house at Chelsea.

HOANG-HAI, or WHANG-HAI. [YELLOW SEA.]

HOANG-HO. [YELLOW RIVER.]

HOAR FROST, a congelation of dew and mist, formed by the temperature of the atmosphere suddenly falling below the freezing point, or 32° ; or by the sudden refrigeration of the substances by which their surface moisture is converted into icy particles. Perhaps the face of nature never assumes a more picturesque or pleasing appearance than on the mornings of a strong hoar frost, when the fogs have disappeared, and the bright azure sky gleams over the productions of the earth. But on the return of the solar warmth, the scene rapidly changes, and the spicular and granular particles, of which icy dew is composed, are gradually transformed to their original moisture.

The circumstances of terrestrial radiation, chiefly, but not exclusively, nocturnal, under which the aqueous vapour of the atmosphere becomes condensed upon the bodies in contact with it, have already been discussed and explained at some length in the article DEW. If the temperature of those bodies be reduced below the freezing point of water, hoar frost is produced, the most characteristic form of which differs from dew only 'by being frozen in the moment of deposition, and therefore accreting in crystalline spiculæ.' But it occasionally happens, that after the globules of water constituting dew have been deposited, they are frozen, and become another form of hoar frost. (See Plate 'Frost,' vol. vii.)

From a series of experiments on the formation of hoar frost on various substances, made by Mr. Glaisher of the Greenwich observatory, it was found

that the spikes of hoar frost increased in magnitude in proportion to their distance from the root or stem of grass and leaves, and that the vegetable heat in that region of the plant counteracted the reduction of temperature by radiation. Mr. Glaisher also found that glass, raised one inch high above the ground, was covered with spikes one-sixteenth of an inch in length, and all arranged horizontally at the edges. On metals, such as copper, lead, zinc, tin, iron, &c., there were neither laminæ nor spikes of any kind; but *tin*, raised one inch high, was a little whitened at the edges. On sand there were spikes one-fourth of an inch in length. Chalk was covered with a mass of spikes of about the same length. Of cotton wool, every fibre was incrustated with a beautiful fringe of hoar frost, and there were also a few spikes of ice. Raw wool was richly clustered on each fibre, so as to be about six times its own size; the spikes were three-fourths of an inch in length, and piled one upon another. Sawdust was very beautifully covered with spiculæ fans, formed by several spikes emanating from the same point at all angles greater than 30° with the horizon. These spikes were connected with each other by lateral spikes or bands, the whole forming the appearance of a fan, whose extent was 120° .

The various modes of aggregation of the minute crystals of ice which constitute hoar frost are evidently dependent on differences in the texture, and in the radiating and conducting powers of these materials, and present a field for investigation hitherto little cultivated.

In England, even in the mildest parts, vegetation is liable to be affected at night, from the influence of radiation, by a temperature below the freezing point of water, every month of the year, even in July and August; and spring vegetation is often checked by hoar frost, unless the productions are protected by slight layers of straw, or a fire lighted to windward, during cold clear nights.

Ice is also formed on the stems of plants and on certain inorganic bodies, by a process very different from that resulting in the production of hoar frost, with which, however, it is popularly confounded.

[DEW; FROST, HOAR; RADIATION OF HEAT; SNOW.]

HOARE, WILLIAM, R.A., an historical and portrait painter, born at Bath about the year 1706. He studied at Rome nine years. There is an altarpiece, by Hoare, of Christ bearing the Cross, in the church of St. Michael at Bath; and another of the Lame Man healed at the Pool of Bethesda, in the Octagon Chapel, for which he received 100*l*. and a pew in the chapel. He was one of the original members of the Royal Academy. He died at Bath in 1792.

HOARE, PRINCE, who succeeded Boswell as foreign secretary to the Royal Academy, was the eldest son of William Hoare; he was professionally a painter, but is known as the author of about twenty dramatic pieces, among which are—'No Song, no Supper;' 'Lock and Key;' 'My Grandmother,' and other lively farces. He published in 1806, 'An Inquiry into the requisite Cultivation and Present State of the Arts of Design in England,' 8vo., pp. 270. He died at Brighton in 1834, aged eighty.

HOARE, SIR RICHARD COLT, Baronet, was

born the 9th of December, 1758, and died the 19th of May, 1838. In 1783 he married the eldest daughter of Lord Lyttleton, and she died in 1785, leaving one child, Henry. His father was the first baronet, and in 1787 he succeeded to the baronetcy. He travelled abroad for some years, and published the results in 1818, under the title of 'A Classical Tour through Italy and Sicily.' In 1806 he published a translation of Giralduus, with views, annotations, and a life of Giralduus. In 1807 he visited Ireland, and published a short account of his excursion. But it is as the historian of Wiltshire, his native county, that Sir R. Colt Hoare's reputation is best established.

HOBART-TOWN. [TASMANIA.]

HOBBS, THOMAS, the Philosopher of Malmesbury, so called from a small town in Wiltshire, where he was born, April 5, 1588, somewhat prematurely, from the circumstance of the portentous armada of Spain having affrighted his mother. His father was the minister of the town. He went early to Oxford; and at the age of twenty undertook the office of travelling tutor to the heir-apparent of Cavendish, Lord Hardwicke, afterwards earl of Devonshire. He travelled with his pupil through France and Italy, and he resided in the family for several years after their return to England. During this period he enjoyed the friendship of Bacon, Lord Herbert of Cherbury, Ben Jonson, and the Scotch poet Sir R. Aytoun. In 1628 he published at London a little poem on the 'Wonders of the Peak of Derbyshire;' and there also about the same time his translation of Thucydides. The merit of this translation lies chiefly in the simplicity and force of the language, in which respect it bears a creditable resemblance to the original. His object in publishing it was to bring historical warnings to bear on the minds of his countrymen, then in the ferment of civil troubles. To dissipate the grief occasioned by the early death of his late pupil, he went in 1628 to France with another, Sir Gervase Clifton's son. He there devoted much time to mathematics. But in 1631 he returned to the Cavendish family and accompanied the young lord on the grand tour, in the course of which, at Pisa, he became acquainted with Galileo. In 1637 he returned with his lordship to England. But on the breaking out of the civil war he again quitted England for Paris, and there mixed in congenial society. M. Sorbiere, Father Mersenne, and Gasendi were amongst his friends, and Descartes became his correspondent. About this time he fell sick of a fever, mortal, as he and those about him feared. In this illness he sought religious consolation, not from his Romish friends, who essayed to convert him, but from Dr. Cosin, a learned divine, and according to the ordinances of the Church of England. At Paris, in 1646, he published his work 'De Cive.' While still at Paris he had printed in London—where the press was free, *regni novitas* notwithstanding—in 1650 his treatises on 'Human Nature' and 'De Corpore Politico;' and, in 1651, his great work quaintly designated 'Leviathan.' Singular as the title of this famous book may appear, it will not seem unaccountable if we consider it as having been dictated, either by the fact that its author embodied all earthly might in the sovereign, or by the circumstance that it was considered by

his adversaries a political monstrosity. Although attached to the cause and fortunes of the exiled royal family, and intrusted about this time with the instruction of the prince, afterwards Charles II., in mathematics, his loyalty and religion were virulently impeached on account of the assumptions in his works with regard to the obedience due to rulers *de facto*, and to the supremacy of the sovereign in ecclesiastical matters. To escape assassination, he found it convenient to return to England, then under Cromwell, whom his principles allowed him, at least, to obey. Always fortunate in his intimacies, he now numbered among his friends Harvey the discoverer of the circulation of the blood, Selden the jurist, Cowley the poet, and Vaughan, afterwards chief-justice of the Common Pleas. In 1653 he finally returned to the family of Lord Devonshire, who settled upon him a small pension. In 1654 he published the letters on 'Liberty and Necessity,' detailing the controversy which he had had with Dr. Bramhall, afterwards archbishop of Armagh, while they were in France; and about the same time he commenced a polemical correspondence with Dr. Wallis, the professor of mathematics at Oxford, in the course of which Hobbes had the mortification of having not only his geometrical positions but his loyalty impugned, though happily it afforded him the opportunity of recriminating on Wallis, who had gone some lengths with the republicans. From this contest, long persisted in, Hobbes finally retreated without glory. At the restoration in 1660 he regained some portion of the royal favour, and received a pension of 100*l.* a year out of the privy purse; but the popular voice as represented in Parliament and convocations still ran against him, and in 1666 his 'Leviathan' and 'De Cive' were censured by Parliament. Soon after he was alarmed by the introduction into the House of Commons of the bill for the suppression of atheism and profaneness, which some were officious enough to tell him would be enforced against him. In 1672 Hobbes wrote his own life in Latin verse; and soon after, his translations of Homer into English verse appeared in detached parts. This was the amusement of his old age. It might on that account claim exemption from criticism, if the poem were not, as Pope said it was, below criticism. On this sharp critique Sir W. Molesworth remarks that some may, however, possibly find that the unstudied and unpretending language of Hobbes conveys an idea of Homer less remote from the original than the smooth and glittering lines of Pope and his coadjutors. In 1664 he began to study the law of England, 'looking over the titles of the statutes from Magna Charta downwards, and leaving no one unread.' He also 'diligently read over Littleton's Book of Tenures, and Sir E. Coke's Commentary; in the latter, he says, he found much subtlety, not of the law, but of inference from the law.' Some fruit of this study is seen in the 'Dialogue between a philosopher and a student of the common law.' This tractate is imbued with high prerogative notions, but contains many just strictures on the abuses of the law. It was published in 1678, together with his 'Decameron Physiologicum,' or ten dialogues on natural philosophy; and his 'Rhetoric,' a free translation of that of Aristotle. 'The Behemoth' (Monarch of the Land), containing an account of the

civil wars, was published after his death. It told too much truth, and distributed blame too freely and impartially, to be acceptable to either of the great political parties of the day. Hobbes died at Hardwicke in Derbyshire, 4th December, 1679, aged ninety-one.

HOICHE, LAZARE, born in 1768 near Versailles, of very humble parentage, enlisted in the French Guards at the age of sixteen. During the revolutionary war he served in Flanders as a lieutenant under Dumouriez. Having distinguished himself, he was rapidly promoted, and at the age of twenty-four was made general in command of the army of the Moselle. Upon incurring the displeasure of St. Just, he was thrown into prison at Paris, when his life was saved by the timely overthrow of Robespierre in July, 1794. The convention restored him to his rank, and sent him against the insurgents of La Vendée.

Hoiche now conceived the bold idea of effecting a landing in Ireland, and a fleet having been equipped at Brest with great secrecy, he embarked his troops in December, 1796; but, being separated by a storm from the rest of the fleet, he was obliged to return to France without effecting anything.

In the quarrel which took place between the Directory and the Legislative Councils, Hoiche took the part of the Executive, and began to direct some of his forces towards Paris in order to support the Directory. For this he was denounced by the Councils, and Bonaparte, meantime, having offered the support of his own army of Italy, the Directory declined Hoiche's services, and made use of Angereau to effect the coup d'état of Fructidor. Hoiche returned to his head-quarters at Wetzlar, where he was seized by a sudden illness, of which he died September 15, 1797. The symptoms of the disease gave rise to suspicions of poison. His life has been written by Rousselin in two volumes 8vo.

HOCK-TIDE, among our mediæval ancestors, a day set apart for sports and public rejoicings, in celebration of the slaughter and expulsion of the Danes, by which the country was freed from their oppression. It was the second Tuesday after Easter, and formed a kind of epoch or period from which leases or other written agreements were dated.

HODDESDON. [HERTFORDSHIRE.]

HODGES, WILLIAM, R.A., was born in London about the year 1744. His father was a blacksmith. He was a pupil of Wilson.

In 1772 Hodges accompanied Captain Cook as draughtsman on his second voyage to the South Seas; and his drawings were published in Cook's narrative. He then went to India, where he realized a considerable fortune. He was elected a member of the Royal Academy in 1787. About 1790 he made a tour on the continent of Europe, and exhibited a view of St. Petersburg at the Royal Academy in 1793. In 1795, he established a bank at Dartmouth in Devonshire, which broke two years afterwards. The shock brought on the death of Hodges, March 6, 1797.

In style Hodges imitated Wilson, but with little success. His best works are—a view of Windsor from the Great Park, and three or four views painted in India.

HODOMETER, is an instrument consisting of a

species of clockwork connected with the axle of a conveyance, and having an index and dial to show the exact distance the vehicle has traversed.

HODY, HUMPHREY, D.D., was born January 1, 1659, at Oldcombe, in Somersetshire. He was educated at Oxford, took his degree of M.A. in 1682, and was elected in 1684 a fellow of Wadham College. The works by which Hody was principally known among his contemporaries were those which he published respecting the bishops who had been deprived of their bishoprics during the reign of William and Mary for refusing to take the oath of allegiance. In 1693 Hody published 'The Case of Sees vacant by an Uncanonical Deprivation' (4to., London, 1693). He was appointed domestic chaplain to Tillotson, archbishop of Canterbury, which office he also held under his successor. He was presented with a living in London, and was appointed Regius professor of Greek at Oxford in 1698, and archdeacon of Oxford in 1704. He died on the 20th of January, 1706.

He founded ten scholarships at Wadham College, in order to promote the study of the Greek and Hebrew languages.

HOE, HORSE-HOEING. The hoe is an instrument used in gardens and in the fields for loosening the earth, and destroying the weeds between plants. It has various forms. The most common hoe consists of a blade or flat piece of iron, with an eye in which a handle is inserted at an acute angle with the plane of the blade. This hoe is used by striking the edge of it down into the ground, and the earth is moved by drawing the handle towards the workman. Another hoe has the handle at a very obtuse angle, and is used by pushing it forward and cutting off the weeds an inch or less under the surface of the ground. Hoes are made of different sizes and shapes according to the work which is to be done. When the earth is to be stirred between plants which are very near to each other, the hoe is narrow and pointed, so that the smallest weed may be taken out close to the growing plant. When the distance is considerable, the hoe is wide, and sometimes compounded of several hoes, in order to stir a greater width of earth at once.

One of the greatest improvements in practical agriculture has been the introduction of the hoe into the field for every kind of crop. Peas and beans were probably the first crops which were sown in rows for the purpose of hoeing the intervals; potatoes, turnips, and carrots were probably the next, and the good effects produced on these crops, by stirring and hoeing have led to the drilling of every other kind of produce which is apt to be injured by weeds. Hand-hoeing not having been found sufficiently expeditious on a large scale, a hoe has been invented of a larger form, to be drawn by a horse. The rows have in consequence been widened, and this has introduced the horse-hoeing husbandry. The greatest promoter of this system was Jethro Tull. [TULL, JETHRO.]

The simple horse-hoe is an instrument with a beam like a plough, and two stilts or handles, but much lighter; in this beam is inserted, instead of a coulter, the end of an iron hoe, of the proper breadth to stir the whole surface between the rows. A small wheel is generally added to keep the hoe at a proper depth in the soil.

A variety of horse-hoes have been invented of more or less complicated forms; but the object of them all is the same, viz., to stir the ground between the rows, and destroy the weeds as fast as they appear. The horse-hoe is now chiefly used in the cultivation of peas, beans, potatoes, cabbages, turnips, and carrots. (See Plates, 'Agricultural Implements,' vol. i.)

A horse-hoe, in which a framework 8 or 10 feet wide, supported on large wheels, carries twelve to twenty hoes attached to coulters hanging at intervals of a few inches from each other, is now used in the cultivation of drilled corn crops during the earlier stages of their growth. The width cultivated and number of intervals hoed at once, correspond exactly with the width and rows which had been sown at once by the drill, so that it only needs that the hoe be placed on the exact rows which were sown at one and the same time, and any crookedness or unevenness in the row will be followed by the hoes. With a hoe of this kind one horse will cultivate from six to eight acres a day.

The effect of hoeing is remarkable in very dry weather. Although the stirring of the soil would seem to extract what little moisture there might be in it, and the weeds wither on its surface, it soon appears that, on the contrary, moisture is attracted or produced, and the plants which drooped before appear refreshed and invigorated.

The operation of hoeing cannot be performed too soon after the plant has shot out its roots, because the ground may then be stirred very near the young plant without danger, and the roots will spread readily in the newly stirred soil.

The best time for hoeing stiff soils is when they are neither wet nor dry; when the surface is slightly caked, but there is moisture below it, and when the weather is dry after some rain. Light soils can be hoed at any time, and require it oftener than the heavy, especially in showery weather.

HOE'S MACHINE. [PRINTING.]

HOERBERG, PEHR, a Swedish painter, was born in a village of Småland, in 1746; his father was a private soldier and extremely poor. By the time he was twenty-two years of age, he contrived to learn so much from one painter and another in his own district, that he was enabled to maintain himself and a wife by his paintings. In 1784, in his thirty-eighth year, he became a student in the Royal Academy of Arts at Stockholm, in which he obtained two prizes, and made rapid progress. In 1790 he established himself at Olstorp in East Götaland, and in 1797 he was elected a member of the Swedish Academy, and was appointed historical painter to the king. He died in 1816.

There are eighty-seven altar-pieces by Hoerberg in Sweden, five of which are copies; his paintings altogether amount to about 700, mostly religious.

HOF, a town in the circle of Upper Franconia, Bavaria, capital of a district on the Saale, and on the Saxon-Bavarian Railway, 30 miles N. E. of Bayreuth. It was ravaged by fire in 1823, since which it has been regularly built, and it has a gymnasium and library, and manufactures of muslins, yarns, woollen stuffs, leather, and colours. There are iron mines and marble quarries in its vicinity. In 1861 the population of the town was 12,018.

HOFFMANN, FRIEDRICH, was born at Halle in Saxony, in 1660, of a family which had been engaged for two centuries in the practice of medicine. After having graduated and received his diploma at Jena, he established himself as a physician at Minden in 1682. In 1684 he travelled through Holland and England, and on his return was appointed physician to Frederick William, elector of Brandenburg, and to the garrison of Minden. In 1688 he removed to Halberstadt, and having gained considerable celebrity both by his successful practice and by his writings, he was invited by Frederick III., elector of Saxony, afterwards king of Prussia, to take the chief professorship of medicine in the University of Halle, which had just been founded. He accepted this appointment in 1693, composed the statutes of the Institution, and retained the professorship with a reputation scarcely inferior to that of his great colleague, Stahl, till 1742, the year in which he died. As a practical physician Hoffmann enjoyed a celebrity second only to that of Boerhaave, who was the contemporary professor of medicine at Leyden. His works were well known and esteemed throughout Europe, and he was admitted a member of the scientific societies of London, Berlin, Petersburg, and other cities. He was a very voluminous writer. Hoffmann's knowledge of chemistry and pharmacy was extensive, and we owe to him the discovery and first introduction of the Seidlitz waters and the purgative salt obtained from them.

The best edition of his complete works is that published at Geneva in 1748, in six vols. folio; and his best treatises are the 'Medicina Rationalis Systematica,' which occupies the first three volumes, and the 'Consiliarii Medici.'

HOFFMANN, ERNST THEODOR WILHELM (or AMADEUS, the name he assumed instead of Wilhelm), one of the most original or rather, perhaps, eccentric writers of Germany, was born January 24, 1776, at Königsberg, in East Prussia. Soon after his birth his father and mother separated and he was brought up by an uncle, by whom he was induced, against his inclination, which led him to the cultivation of music and drawing, to study the law. From 1796 to 1800 he continued to prosecute his studies with great diligence in the courts at Glogau in Silesia and in Berlin, still, however, pursuing his favourite studies at every possible interval. In March, 1800, he was appointed assessor to the government of Posen, and thence, through the patronage of General Zastrow, removed to be a judge at Plock in Poland in 1802, and to Warsaw in a similar capacity, in 1803. Hoffmann was an excellent magistrate, and highly esteemed in Warsaw; but on the entry of the French troops into that town in 1806, he found himself at once without employment, without fortune, and without the prospect of any office in his then distracted native country. He determined boldly to make his other acquisitions serviceable to his support. He taught music, wrote articles for the *Allgemeine Musicalische Zeitung*, of Leipzig, and accepted in 1808 the situation of musical director of the theatre at Bamberg. Afterwards, in 1813, he filled the same office to the Dresden theatre till 1815. After the downfall of Napoleon, and the complete restoration of the Prussian kingdom, he was upon petition readmitted as judge, and soon afterwards appointed

to a seat in the royal judiciary court at Berlin, which he filled with great credit to himself as a judge till his death on July 21, 1822.

Hoffmann was small and weak of body, but for many years he laboured with extreme ardour. Besides his professional acquirements, which were highly estimated by his colleagues, he composed the music and text of many operas: the first was the music only to Göthe's 'Scherz, List, and Rache' (Jest, Trick, and Revenge), which was performed at Posen in 1800. He also produced a number of caricatures, highly popular at the time, of the foreign invaders of his country, and especially of Bonaparte. His first series of tales appeared at Bamberg in 1814, 'Phantasiestücken in Callots Manier;' and similar tales were continued even on his deathbed. They are all distinguished by a fertile wildness of imagination, considerable humour, vivid descriptions of the beauties of nature, much insight into the inconsistencies of the human character, and sly sarcasm. His works form fifteen volumes in 18mo., of which a portion have been translated into French; but only two, 'The Sandman' and 'St. Sylvester's Night,' which appeared in *Blackwood's Magazine*, have been rendered into English.

HOFLAND, MRS. BARBARA, the well-known authoress, was the widow of Mr. Hofland, landscape painter, and daughter of Mr. Wreaks of Sheffield, where she was born in 1770. She lost her father at an early age, and at twenty-six married Mr. T. B. Hoole, a young man of high respectability, who died two years afterwards, and left her, with one child, in straitened circumstances. This obliged her to have recourse to her educational talents for the means of subsistence. She commenced her literary career in 1805, by the publication of a volume of poems by subscription, which was extensively patronized, and enabled her, from the proceeds, to establish a respectable school at Harrowgate, where she was in the habit of occasionally writing and publishing various works of a moral or amusing tendency. She afterwards contracted a second marriage with Mr. Hofland, the eminent landscape painter. But she still continued to devote herself to the pursuit of light and elegant literature. Among the principal of her works may be mentioned the novels of 'Beatrice,' 'Emily,' the 'Son of a Genius,' 'Captives in India,' 'Self-denial,' 'Adelaide,' 'Decision,' the 'Czarina,' 'Tales of the Priory,' and 'Tales of the Manor.'

Mrs. Hofland was a woman of exemplary character, who bore all the troubles and afflictions of life with enduring patience; and the best evidence of her claims as an authoress is the fact that she produced about seventy different works, of which 300,000 copies have been circulated in this country alone. In America, also, their sale has been very extensive, 20,000 copies of the 'Czarina' having been printed and sold there on its first appearance. Her works have also been translated into various continental languages. She died in 1845, and was interred at Richmond in Surrey.

HOFWYL, the name of the estate on which was established the educational institution of Mons. de Fellenberg. It is situated in a valley about three leagues from Berne, in Switzerland, and consists of a number of distinct buildings surrounded by about

250 acres of land. The founder had for his object the improvement of the condition and character of all classes of society by means of an education adapted to their respective wants. To effect this, he divided the institution into classes, of which the higher, the sons of wealthy parents, paid a large yearly sum; the second class a smaller sum; and the lowest class was received without payment. All were instructed in agriculture and the trades connected therewith, all of which were practised on the estate. All the classes also were instructed in the usual branches of school education, and even the lower class in the sciences connected with agriculture; but these were carried farther in the second class, and the highest class had a still wider range. The upper class was commenced in 1808, and the lowest was added in 1810: the middle class was not introduced till 1830. Fellenberg was enthusiastic, and succeeded in imparting much knowledge to his pupils, of whom he had usually about one hundred who paid stipends, and one hundred who were boarded, clothed, and educated for their labour. Fellenberg died in 1844, lamented and respected. It was Fellenberg's wish to have his institution adopted by the state, but this has not been done. It is, however, still carried on—Dr. Edward Müller being the principal.

HOG. The wide dispersion of the domestic hog, and its usefulness to man, need no comment. It is omnivorous, and thrives on every kind of food, vegetable or animal. The sow may bear two litters in the year, each consisting of eight, ten, twelve, or fourteen young, sometimes more.

There are several varieties of the domestic hog. Many of the older breeds closely resembled the wild animal, their primitive origin. Their size was large and their flesh good, but they fattened slowly—a great fault, since the more rapidly the hog fattens, and the earlier he can be made to increase in flesh without increasing in bone, the greater is the advantage to the breeder. The small original Chinese breed is remarkable for this quality, and also for productiveness; and when by judicious crossing the size is increased, a great point is attained. The Chinese pig is short in the head, with ears pricked up and pointing backwards, very wide in the cheek, high in the chine, and short in the leg; the young pigs make delicate roasters at a month old, and, when dairy-fed, excellent porkers at about three months old.

The breed in this country nearest to the Chinese is the Suffolk. These pigs are generally white, with pointed ears, broad chest and loin, and a compact outline. The suckling roasters and the porkers are excellent, and they make fine bacon hogs at twelve or fifteen months old.

The Essex breed approaches the Neapolitan, and is probably derived from the latter. Some are black and white, but the pure breed is black. This breed is admirable, and, when directly crossed with the Neapolitan, produces an intermixed progeny of superior qualities, fattening at an early age, and to an astonishing degree, with delicacy of flesh. The true Neapolitan hog is black, without any hair, very plump, with sharp ears. No breed can excel it in the aptitude to fatten; but it is tender, and winter litters are liable to perish from cold. It is very valuable as a cross with some of our hardier sorts, especially with the Berkshire, a noted race in the

present day in consequence chiefly of this admixture of blood. Indeed, a mixture of the Berkshire, Chinese, and Neapolitan breeds may, by careful selection, and attention to the principle of not interbreeding in one strain too far, be brought to the highest degree of perfection.

Colour is chiefly a matter of fancy, but black pigs have the thinnest skin, and suffer less from the sun in summer, and hence they are less liable to cutaneous diseases. Experience teaches that when sows and boars are too nearly related the fecundity greatly diminishes. The very large breeds are not generally considered so profitable as the smaller ones, as they do not so soon come to maturity, and cannot be profitably put up to fatten till they are eighteen or twenty months old. For delicate bacon the hogs killed at a twelvemonth old, and weighing from ten to twelve score are much preferred. It is a great mistake to suppose the hog loves dirt. If it can keep itself clean it will do so, and its wallowing in the mud arises generally from heat and itching of the skin in warm weather, which is relieved by rolling in the cold mud. If hogs have plenty of straw and clean water they will never be dirty; and nothing makes them thrive so quickly or pleases them more than being washed and curried regularly.

The fat of the hog, which is produced in a thick layer under the skin, is an article of commerce and of various uses under the name of lard. The skin is made into leather, which is particularly esteemed for saddles. The bristles are much used for brush-making.

In order to manage hogs profitably, a regular system must be pursued. Proper sties for breeding sows, boars, feeding-hogs, and porkers, must be constructed with due attention to comfort and cleanliness. Regularity in feeding, attention to the quality of the food, according to the purpose designed, increasing it from less nutritious articles to a full diet, from boiled potatoes mixed with bran, to pea-meal, barley meal, skimmed milk, &c., are points of importance. Conveniences, as boilers and outhouses, for the preparation and storing of food, are also essential, and so is due cleanliness of the troughs.

HOGARTH, WILLIAM, the celebrated satirist and painter, was born in the parish of St. Bartholomew, London, on the 10th of December, 1697. His father, originally a schoolmaster of Westmoreland, was then established in London as a printer's reader or corrector of the press. The son was apprenticed at an early age to Ellis Gamble, a silversmith, who had a shop in Cranbourn Alley, Leicester Square, and Hogarth was brought up as an engraver of crests and ciphers on metal. In 1718, however, when the term of his apprenticeship had expired, he forsook silver-engraving for the higher branch of the art on copper, and procured from the booksellers more congenial employment. His first known illustrations are the twelve small plates executed for Butler's 'Hudibras' in 1726, which have been copied for subsequent editions of that poem; and though Hogarth engraved many book-prints about this time, he found engraving such a miserable profession that he got sometimes for his plates a very little more than the value of the copper; he therefore adopted portrait-painting as his main support. In this branch of art he did much better; he ventured to take a wife in

1730; and married the only daughter of Sir James Thornhill the painter, in spite of her father's opposition. His marriage seems to have acted as a great stimulus to his exertions, for in a very few years, from an obscure engraver we find him developed into an excellent painter, without a rival in his own satirical sphere, and with few equals in the mere technical manipulations of his art. Of his several moral series of excellent pictures, produced from 1734 to 1744 inclusive, the most admirable is now in the National Gallery, known as the 'Marriage à la Mode,' in six scenes. They were sold by auction by Hogarth in 1750, when, to the painter's extreme disappointment, only one bidder appeared. To him the pictures were knocked down at 110 guineas: the frames alone had cost the painter 24 guineas. They were in 1797 bought for 1381*l.* by Mr. Angerstein, with whose collection they were purchased by the nation in 1824. The nation possesses also an excellent specimen of Hogarth's portrait-painting in the picture of himself and his dog Trump, executed in 1745, which formed likewise one of the Angerstein collection; it was bought by Mr. Angerstein after the death of Mrs. Hogarth in 1789. Another very good portrait by Hogarth is that of Captain Coram at the Foundling Hospital. Of his pictures, the 'Rake's Progress' and the 'Harlot's Progress' are, like nearly all his other works, well known from prints. In 1753 he appeared as an author. 'The Analysis of Beauty, written with a view of fixing the fluctuating ideas of taste,' was published in that year. In 1757 he was appointed sergeant painter to the king. He died at his own house in Leicester Square, October 26, 1764, and was buried in a vault at Chiswick, where he had a villa in which he generally resided in the summer. 'Hogarth,' says Walpole, 'resembles Butler; but his subjects are more universal, and amidst all his pleasantry he observes the true end of comedy—reformation. There is always a moral to his pictures. Sometimes he rose to tragedy, not in the catastrophe of kings and heroes, but in marking how vice conducts insensibly and incidentally to misery and shame. He warns against encouraging cruelty and idleness in young minds, and discerns how the different vices of the great and vulgar lead by various paths to the same unhappiness.' There are several sets of Hogarth's works published, but most are copies. The best original set is that sold by the Boydells after the death of Mrs. Hogarth, in one hundred and ten plates.—(Walpole, Nichols, Ireland, &c.) In the South Kensington Museum there are seven of his pictures, consisting of his own portrait and the series of the *Marriage à la Mode*.

HOGG, JAMES, a Scottish poet, generally known by his poetical name of 'The Ettrick Shepherd,' was a native of Ettrick Forest in Selkirkshire. According to the last of the numerous accounts which he gave of his life, he was born in 1772, on the 25th of January, the anniversary of Burns' birthday. But the parish register of Ettrick records his baptism as having taken place on the 9th of December, 1770. His forefathers for several generations were shepherds, distinguished by their integrity and skill; but his father having saved a little money, took a lease of a farm in Ettrick and commenced dealing in sheep. In the course of a few years, however, he was ruined, and lost his whole

property. The poet's mother, Margaret Laidlaw, was a woman of remarkable vivacity, humour, and spirit, but deeply imbued with superstition, and was celebrated over the whole district as a reciter of ancient ballads and traditions. Hogg was only seven years of age at the time of his father's bankruptcy, and was in consequence obliged to go to service with a neighbouring farmer as cowherd. His school education must have been very imperfect; but following an occupation which at certain seasons afforded him abundance of leisure, and living in a picturesque district famous for its historic and poetic associations, he was from early years familiar with all the legendary lore and ballad strains of the Border, as well as with the Sacred Scriptures and the usual household works of the Scottish peasant, and these have evidently exercised an important influence in the formation of his character. After serving a number of masters as a shepherd, Hogg entered at Whitsunday, 1790, into the service of Mr. Laidlaw of Blackhouse in Yarrow, father of William Laidlaw, the confidential friend of Sir Walter Scott. There he remained for nine years, had access to a considerable collection of books, and received every facility for the cultivation of his poetical genius. It was through William Laidlaw, too, that he was introduced to Sir Walter Scott, who was greatly interested in Hogg's character and history, and was ever after one of his best friends. It is difficult to say at what period the Shepherd's poetical genius first began to display itself. His first printed piece, entitled 'The Mistakes of a Night,' appeared in the *Scots Magazine* for October, 1794. In 1801 he published hastily a small collection of his verses, which he says was full of errors and imperfections, and he afterwards regretted that he had allowed these crude productions to see the light. In 1807 a volume of his songs and poems, of greatly superior merit, appeared under the title of the 'Mountain Bard,' the profits of which, and of a treatise on the diseases of sheep, amounted to 800*l*. He had previously lost all his savings as a shepherd in a sheep-farming speculation in the island of Harris; out undeterred by this failure, he now took a farm in Dumfriesshire, which proved a ruinous concern, and in three years left him penniless. Failing to obtain employment as a shepherd, he took his plaid about his shoulders, he says, and set off for Edinburgh in February, 1810, determined, since no better could do, to push his fortune as a literary man. His first effort was a collection of songs entitled 'The Forest Minstrel.' He then tried a weekly periodical called the *Spy*. In spite of all his efforts, however, it would have fared ill with him but for the unwearied kindness and generosity of Mr. John Grieve, a worthy hat manufacturer in Edinburgh, who supported Hogg through all his difficulties and privations, and suffered him to want for nothing. At length, in 1813, the publication of 'The Queen's Wake,' the best of his works, established the Shepherd's reputation as a poet on a permanent and lofty basis. It was followed by 'Madoc of the Moor,' a poem in the Spenserian stanza; 'The Pilgrims of the Sun,' in blank verse; 'The Poetic Mirror,' a collection of pieces in imitation of some living poets; 'Queen Hynde,' and other poetical pieces; and also by the 'Winter Evening Tales;' 'The Brownie of Bodsbeck;' 'The Confessions of a Justified Sinner;'

'The Three Perils of Man,' and other novels of very unequal merit. The duke of Buccleuch, in compliance with the deathbed request of his duchess in 1814, that he would be kind to the Ettrick bard, gave him a liferent of a small moorland farm at Altrive in Yarrow, where he built a cottage and went to reside in 1817. Three years later he made an advantageous marriage, and desirous once more to try his fortune as a sheep farmer, he took the large farm of Mount Bengier from the duke of Buccleuch; but by the end of his nine years' lease the poet was once more a ruined man. The remainder of his life, with the exception of a visit to London in 1831, and an occasional residence of a few weeks in Edinburgh, was spent at Altrive in the enjoyment of domestic happiness and social hospitality, presiding at Border festivities, and spending much of his time in fishing and field sports, of which he was passionately fond. The inimitable 'Noctes Ambrosianæ' kept his name constantly before the public; and though this strange miscellany of poetry, eloquence, wit, fun, and coarse humour, raised a prejudice against the Shepherd in some quarters by frequently representing him in grotesque and ludicrous aspects, yet on the other hand it conveyed an impression much too exalted of his genius, sagacity, and colloquial powers. He died, 21st November, 1835, leaving a widow and five children, and was buried in the churchyard of Ettrick.

The works of the Ettrick Shepherd have been collected since his death, and are comprised in eleven volumes. His writings, both in prose and verse, are very unequal, but they contain not a little which the world will not willingly let die. In grasp of intellect and depth of passion, Hogg was greatly inferior to Burns; but on the other hand, his genius was more discursive, playful, and fanciful. His masterpiece, 'The Queen's Wake,' is admirable, both in design and execution, and the tales and legends which it contains are worthy of a place among the lyric poetry of Scotland's greatest masters of song. 'Kilmeny' is one of the finest fairy tales that ever was conceived or penned, and its scenes of supernatural splendour, purity, and happiness, are altogether inimitable. Some of the Shepherd's songs and minor poems, such as 'The Skylark,' 'When the Kye come hame,' 'Donald Macdonald,' 'The Evening Star,' &c., will last as long as the language. The best of his prose works is 'The Shepherd's Calendar,' which contains a genuine and affecting representation of pastoral life. But Hogg had no skill either in the delineation of character or in arranging the incidents of a story, and his tales are often disfigured by coarseness and exaggeration. The Shepherd's natural character was frank, kind, simple, and enthusiastic as that of a child, generous and hospitable far beyond his means; but he was vain, thoughtless, rash, and improvident, and consequently seldom free from pecuniary difficulties. 'Requiescat in pace,' says Lockhart; 'there never will be such another Ettrick Shepherd again.'

HOGSHEAD, an ancient measure of liquids, which, not being mentioned in the Act 5 George IV., cannot now be considered as having any legal existence.

The hogshead of wine was 2 wine barrels, or 63 old wine gallons; the London hogshead of ale was 1½ ale barrel, or 48 ale gallons; the London hogshead of beer was 1½ beer barrel, or 54 beer gallons;

and the ale and beer hogshead for the rest of England was $1\frac{1}{2}$ barrel, or 51 gallons. All excise measurements being now made in gallons, the term hogshead remains in use only as the name of a large cask.

HOHENLINDEN, a small village in Upper Saxony, famous as the scene of a sanguinary battle between the French and Austrians on the 3rd of December, 1800. The former were commanded by Moreau, and the latter by the Archduke John. The battle was fought amidst drifting snow, and ended in the complete defeat of the Austrians, who had 8000 men killed and wounded, and 11,000 made prisoners, including 200 officers. They also lost 100 pieces of artillery. The French had 5000 men killed and wounded. The battle was almost immediately followed by the peace of Lunéville. It was made the subject of a fine poem by Campbell, commencing—

'On Linden, when the sun was low.'

HOHENLOHE. [JAXT.]

HOHENZOLLERN HECHINGEN and HOHENZOLLERN SIGMARINGEN, two former principalities of Germany, so called from a very ancient family of the same name, whose original seat was the ancient castle of Zollern, or Hohenzollern, which stands within two miles of Hechingen, on the road from Stuttgart to Schaffhausen. The family, which takes its origin from Count Thassilo, who died in 800, was divided towards the close of the sixteenth century into the two branches of Hohenzollern Sigmaringen and Hohenzollern Hechingen. The territory is entirely inclosed between Württemberg and Baden; its surface is mountainous, and the soil is in general stony. Corn more than enough for the consumption is raised; flax is extensively cultivated; horned cattle and sheep are numerous; and the forests abound with fine timber. There are iron mines in the northern part. The manufactures are unimportant. The principalities were made over to Prussia in 1849. The area is 451 square miles, and the population in 1861 was 64,675. From the younger or Hechingen branch, the royal family of Prussia is descended. In both principalities the inhabitants are all Catholics.

HOLASTER, a genus of fossil *Echinidæ*, proposed by M. Agassiz to include species once ranked as *Spatangi*. *Spatangus subglobosus* (Leake), *Sp. planus* (Mantell), and *Sp. hemisphericus* (Phillips), are examples. The species occur almost exclusively in the chalk formation.

HOLBEACH. [LINCOLNSHIRE.]

HOLBEIN, HANS, is considered by the Germans to be the best of their early painters next to Albert Dürer, whom he, however, excelled in portraits. He was born in 1497, at Grünstadt. He was instructed in the art of painting by his father, whom he soon excelled. Accompanying his father to Basel, Holbein painted several portraits of Erasmus, who gave him a letter of recommendation to Sir Thomas More, and he came to England in 1526. He was subsequently taken into the service of Henry VIII., and painted a large number of pictures in this country, principally portraits, for which he was munificently rewarded. Several portraits by him are in the Hampton Court Gallery. He died at London, of the plague, in 1554.

HOLBERG, LUDWIG, BARON, was born at Bergen in Norway, in 1684. Having completed his

studies at Copenhagen, he became a private tutor. He was eventually, in 1718, appointed professor of metaphysics, and in 1720 professor of eloquence at Copenhagen. He now astonished and delighted his countrymen by his Satires, and his comic poem of 'Peder Paars.' This production has acquired for its author the title of the Danish Butler.

The most formidable rival to the author of 'Peder Paars' is Holberg himself as a dramatist, for his comedies have rendered the poem only his secondary title to fame. His 'Metamorphoses,' in which he has reversed Ovid's system, transforming animals into men, instead of men into animals, is ingenious in idea and happy in execution. But that to which some have assigned the foremost place among his productions is 'Niels Klim's Subterraneous Journey,' first published in 1741, and written in Latin, but translated not only into Danish, but into almost every other European tongue. History, biography, philosophy, politics, all employed his pen by turns. He died January 27, 1754, in his seventieth year. He was created a baron by Frederick V. of Denmark.

HOLCROFT, THOMAS, born December 10, 1745.

His father kept a shoemaker's shop in Leicester Fields, London, and occasionally dealt in horses. When very young Holcroft became a stable-boy in racing-stables at Newmarket, and continued in the service of training-grooms till his seventeenth year, after which he lived a desultory life till twenty, when he married. About this time he had proceeded far enough in self-education to commit his performances to the columns of the *Whitehall Evening Post*; but this whim soon gave way to others, and in a short time he found himself an actor. In 1780, he turned author, producing first a novel, then a comedy, and afterwards some poems, which were followed in their turn by a series of plays, and by translations of French works, of which those most remembered at present are—'Tales of the Castle,' and 'The Marriage of Figaro.' The play by which he is principally known is the 'Road to Ruin.' In 1789 he lost his son, and in 1790 his third wife. Four years afterwards he was implicated in the political trials relative to the Society for Constitutional Information. He lived much in Germany and occasionally in Paris. He died March 23, 1809.

HOLCUS, a genus of grasses belonging to the tribe *Seslericeæ*. There are two British species of this genus. *H. lanatus* grows in meadows and pastures. *H. mollis* grows in thickets or open places on a light soil. The *H. cernuus* of Willdenow, and the *H. sorghum* of Linnaeus, are now referred to the genus *Sorghum*.

HOLD, is that part of a ship which lies below the water line. It extends throughout the length of the ship, and is under the lower-deck. Light and ventilation are procured through the hatchways. In men-of-war the provisions, water, and miscellaneous articles are stored in the hold—in merchant ships the cargo is usually carried there. It is sometimes divided into sections, as forehold, mainhold, and afterhold.

HOLDERNESS. [YORKSHIRE.]

HOLDING, in the law of Scotland, is a term employed in feudal law to express the nature of the right conferred by the superior on the vassal, and the relation subsisting between them. There were

originally five kinds of holding, of which three still exist.

1. *Ward-holding*, so called from the privilege resulting from it to the superior, of *warding* or being guardian of the vassal's person and estate during his minority, was the proper feudal tenure of the country. It was military in its nature and origin, and was conferred for such services as supporting the superior in war, or contributing a certain number of horses and men when he took the field. Shortly after the rebellion of 1745, this holding was abolished by the act 20 Geo. II. c. 50; and lands held ward of the crown or prince were converted into blench-holdings, whilst those held from subject superiors were changed into feu-holdings, the duties being adjusted on a uniform scale, prepared by the Court of Session.

2. *Mortification*, or *Mort-main*, when grants were made to churches, religious houses, or for pious uses, for a *reddendo*, or return of *preces et lacrymæ*. During the religious excitement produced by the Reformation this tenure was abolished, on the ground of its being superstitious. But lands may still be mortified for charitable purposes, under a holding either feu or blench, according to circumstances.

3. *Feu-farm*, was for long esteemed an ignoble tenure, though it seems to have been known at an early period of the law. It is mentioned for the first time by the Act 1457, c. 71, and was introduced for the encouragement of agriculture throughout the kingdom. The return for which a grant with this holding is given, is either services proper to, and connected with a farm, as ploughing, reaping, &c., or more commonly a yearly rent in money or grain. This is now the ordinary tenure by which lands are held; and it bears, in many respects, a strong resemblance to the Roman right of *emphyteusis*.

4. *Blench-farm* (perhaps the *feudum francum* of the Lombards), is that by which the vassal becomes bound to pay to the superior an annual elusory duty, such as a penny money, a hawk, a pair of gilt spurs, as an acknowledgment of superiority. The act 1606, c. 14, forbade the taking of money in lands held blench of the crown, when the duties were stated in the charter to be exigible in kind.

5. *Burgage-holding*, is that by which burghs-royal hold of the king the lands contained in their charters of erection. It is regarded by Sir Thomas Craig ('De Feudis,' 81, s. 36) as a species of ward-holding, and the specified services are watching and warding. As the royal burgh is the king's vassal, all burgage holders hold immediately of the crown, the magistrates in givingsasine acting, not as superiors, but merely as the king's bailies.—(Erskine, *Prin.* p. 236.)

HOLETRA (Gr. *holos*, 'entire,' and *etron*, 'the abdomen'), an order of Spiders, in which the thorax and the abdomen are closely joined, and appear as one.

HOLIDAY, a term which, legally speaking, is restricted to Christmas Day, Good Friday, and any other day appointed by act of Parliament to be kept as a fast or public thanksgiving. Bills of exchange falling due on these days must be paid the day before. In public offices and law courts, in addition to Christmas Day and Good Friday, the Queen's birthday, and in some instances other days, are kept as holidays.

HOLINSHED, RAPHAEL, was born probably

during the first half of the sixteenth century. Anthony à Wood says that he 'was educated at one of the universities, and was a minister of God's word;' it appears most probable that he was chaplain or steward to Thomas Burdet of Bromcote in Warwickshire. He died about 1580.

Holinshed is an important authority in English history. The first edition of his history is a very scarce black-letter in two vols. folio, adorned by numerous wood-cuts. The second edition omits these adornments, and has suffered also from the censorship of the times, which compelled the cancelling of several sheets. It consists of the following items:— 'Description of England,' by Harrison; of 'Ireland,' by Stanihurst; and of 'Scotland,' from the Latin of Hector Boethius, by W. H(arri)son; 'History of England,' by R. H(olins)hed; of 'Ireland till the Conquest,' from Giraldus Cambrensis, by J. Hooker (an uncle of the divine); 'till 1509,' by Holinshed; and 'till 1586,' by Hooker and Stanihurst; and of 'Scotland,' till 1571, by Holinshed, and continued by others.

HOLKAR, MULHAR RAO, was a Mahratta soldier, who, having been instrumental in extending the conquests of his nation, under the first Peshwa, towards the north of India, received a grant of land in Malwa about 1736. Ultimately one-half of that large province passed under his rule; and before his death in 1766, he had rendered himself, in all but name, independent of his titular superior. He was succeeded by his grandson, a minor; but this boy soon died, and the inheritance passed to Tuckagee Holkar, who, dying in 1797, left four sons, whose patrimony was usurped for a time by Scindia, the most powerful of the Mahratta chiefs. In 1802 Jeswunt Rao Holkar, the third son, defeated Scindia, and re-established himself in Malwa. The Marquis Wellesley, then governor-general, refused, however, to recognize his title, and in 1804 commenced a war against him, which was terminated at the end of 1805 by a peace which left to him the greater part of his dominions. The violence of his temper ultimately grew into madness; and the last three years of his life were passed in close confinement: he died in 1811. A wretched anarchy succeeded. After the final overthrow of the Mahratta power in 1818, Mulhar, the son of Jeswunt Holkar, was suffered to retain a portion of the dominions, under the protection of the British.

HOLLAND, the name generally given to the kingdom of the NETHERLANDS, but properly applicable only to the two provinces described in the next article.

HOLLAND (NORTH and SOUTH), two contiguous provinces, and the most important in the kingdom of the Netherlands, situated between 51° 45' and 53° 30' N. lat., 3° 45' and 5° 20' E. long., is bounded N. and W. by the German Ocean, E. by the Zuider-zee and the provinces of Utrecht and Guelderland, and S. by Zeeland and North Brabant. The surface is flat, and in many parts below the level of the sea, against which it is protected by the sandy downs on the west coast, and by stupendous dykes built along the shores of the Zuider-zee, the Haarlem-meer, and the banks of the principal rivers. The country is traversed by canals in all directions. A railroad passing from Rotterdam through the

Hague, Leyden, Haarlem, Amsterdam, Utrecht, and thence to Rotterdam, incloses a very important part of the province. The soil is marshy, but has some rich pastures, which support a fine breed of horses, cattle, and sheep. Gardens and orchards are carefully cultivated; barley, oats, peas, beans, mustard, and other seeds, are the chief crops in the northern part of the province; in the southern part more corn is produced. But pasturage prevails much more than arable cultivation; the produce of the dairy farms, butter and cheese, constituting the chief wealth of the landholder. A remarkable feature of the country are the *polders*, a name given to lands that are below the level of the sea or adjacent river, and, having once formed a lake or marsh, have been surrounded by dykes, and cleared of water by means of pumps worked by windmills. The lands thus reclaimed are very fertile, and some of them of great extent, as the Beemster polders, near Edam, in the northern part of the province, which are fifteen miles in circumference; the grain sown in them is sometimes destroyed by water, but rarely, for the mills are always at work, when there is any wind, lifting up the water to such a height as gives it a fall into the nearest river, canal, or sea. The effect produced on foreigners, who visit the polders for the first time, is one of surprise, not unmingled with alarm, at the apparent inversion of the natural order of things; luxuriant corn and rich grass crops growing, and fat cattle and sheep pasturing, where water should lie; while the large sails of the canal barges flit past high above dykes, houses, and trees. A few years ago the Haarlem-meer, or lake, was drained by steam-power by an English company, and more than 40,000 acres of reclaimed land are now divided into farms, under pasturage or tillage. Flowers are cultivated in the tract between Alkmaar and the Hague, but especially about Haarlem. Hemp, flax, and madder are grown. Wood, both for construction and for fuel, is scarce. The manufactures, which are chiefly carried on in the towns, are important. They consist of linen, paper, woollen cloths (for which Leyden is famous), silk, leather, tobacco, sugar, &c. The gin distilleries of Schiedam are very extensive, and have been long celebrated. Large quantities of fine lime are made from the shells gathered on the coast of the German Ocean. The fisheries on the coasts are important, and most industriously prosecuted. The sleekness of the cows and horses, and the cleanliness of the dairies in Holland, are proverbial. The horses are all tender in the hoof.

To the lover of the picturesque the aspect of Holland is tame and uninteresting. The country is one vast plain, diversified neither by mountain, hill, nor knoll. Viewed from the top of a tower or spire, it appears like an extensive marsh intersected by numberless ditches and canals. Yet even the dull monotony of this prospect is relieved by some features of great interest, meadows of wide extent and of the most beautiful verdure covered with large herds of well-fed cattle, sheets of water, clusters of trees, and in the vicinity of large towns elegant villas and parks decorated with statues and busts. Throughout the kingdom the advantages of education are enjoyed in an eminent degree; schools are established in every parish. The universities of Leyden, Utrecht, and Groningen have long been celebrated.

The Dutch may boast of attainments in letters and science, and even in the fine arts. In the former they possess the names of Erasmus, Boerhaave, and Leeuwenhoeck; in the latter those of Rembrandt, and a number of landscape and marine painters.

The Dutch are a laborious, plodding, cleanly, frugal, but upright people. In religion they are Protestant Calvinists, but they have long set the example of the most complete toleration.

NORTH HOLLAND extends north of the Haarlem-meer, and the mouth of the Old Rhine. It has an area of 966 square miles, and a population in 1862 of 554,221. The Amstel and the Vecht flow through the south-east of the province, the Zaan through its centre. The Helder Canal, by which the largest merchant vessels reach Amsterdam direct from the German Ocean without encountering the difficult navigation of the Zuider-zee, runs from Amsterdam to the Mars-diep or strait that separates the Texel from the mainland. It is 120 feet wide, 25 deep, and above 50 miles in length. The chief towns are ALKMAAR; AMSTERDAM; HAARLEM.

Amstelveen is a well-built town with 5100 inhabitants, situated between the Amstel and the Haarlem-meer, and five miles S. by W. from Amsterdam.

Broek, a village of 1200 inhabitants, composed chiefly of retired merchants and their families, is the much bepraised model of the precise neatness and punctilious cleanliness of the Dutch. In fact, it is stated to be the cleanest place in the world. The narrow lanes that intersect it are paved with bricks, strewn with sand or shell, and always clean. No horse or vehicle of any kind is allowed to pass along them. The houses are of wood, painted white and green, and roofed with glazed tiles of different colours. The front doors and windows are never opened except on great occasions, such as a funeral, a wedding, or a christening. The interiors of the houses correspond to the exterior in order, cleanliness, and tidiness; but have more the appearance of large baby-houses than of the dwellings of men. The cow-houses here are curiosities in their way; they are washed out, walls and floors, several times a day; the cows' tails are fastened to hooks in the ceiling, lest they might by accident besmear their sides with them. *Broek* is six miles N. by E. from Amsterdam; it is famous for its sweet-milk cheeses.

Edam, a town of 4024 inhabitants, stands S.E. of the Beemster polders, and near the Zuider-zee, in which it has a good harbour. The export trade in sweet-milk cheese from this port is important; the chief industrial products are salt and fish oil.

Enkhuizen, situated on a peninsula in the Zuider-zee, 28 miles N. by E. from Amsterdam, is a well-built fortified town with 5449 inhabitants. It was formerly the centre of the great deep-sea herring fishery; 400 large vessels used annually to sail from its harbour, which is now nearly choked up with sand. The town possesses nine churches, an hospital, salt-refineries, and a cannon foundry; the town-house with its lofty tower is the most imposing structure. Its commerce is composed chiefly of cattle, butter, cheese, timber, and herrings.

Helder. [HELDER.]

Hilvessum, a small town 16 miles S.E. from Amsterdam, has 1350 inhabitants, who manufacture carpets and calicoes.

Hoorn, a city and fortified seaport, on the *Zuider-zee*, eastward of *Alkmaar*, with which it is connected by a canal, is well built, surrounded by ramparts, and has 10,000 inhabitants. The great fleet of Admiral De Ruyter was built in *Hoorn*. There is still an active trade, chiefly in exports of butter, cheese, provisions, and fish. The manufactures of woollen stuffs, carpets, &c., the shipbuilding and the herring fishery, though still important, are insignificant compared with their former magnitude. Schouten, who first doubled Cape Hoorn or Horn, in 1616, and named it after his native place; and Tasman, the discoverer of Van Diemen's Land and New Zealand, were born at *Hoorn*. The large nets used in the herring fishery were first constructed here.

Medenblik, N.W. of *Enkhuizen*, on the *Zuider-zee*, had formerly an extensive foreign commerce; it has now scarcely any foreign trade, and its population is only 2450. It contains a royal naval academy, and its chief commerce is in timber and cheese. The harbour is large and good.

Naarden, a fortress on the south shore of the *Zuider-zee*, 12 miles E. from *Amsterdam*, has 2620 inhabitants, who manufacture silk and velvet. It forms the key of all the water communication of Holland, and is important for the defence of *Amsterdam*, with which it is connected by a fine canal.

Zaandam (commonly corrupted into *Saardam*), a town of, in 1861, 11,968 inhabitants, on the north shore of the *Y*, and at the mouth of the *Zaan*, which divides it into *Oost-Zaandam* and *West-Zaandam*. The houses are mostly constructed of wood, and painted; each being surrounded by a small canal and completely insulated. From a distance, the town has a most singular appearance; it seems to consist of a line of windmills, some of which are of gigantic size and have houses attached to them, extending along the *Zaan*, and forming a street nearly five miles in length. The number of these mills is variously stated, but it seems to amount to about 700; they are applied to the various purposes of grinding corn, draining the land, sawing timber, making paper, grinding tobacco into snuff, crushing rapeseed to express the oil, grinding colours for the painter, grinding stones into sand for the floors of the Dutch housewife, and grinding the volcanic substance called *trass* into dust in order to form a cement, which hardens under water, and is much used in Holland. The town is often visited for the purpose of seeing the hut in which Peter the Great worked and slept during his short stay here to learn ship-building in 1696.

To North Holland belong the islands *Marken* and *Urk*, in the *Zuider-zee*; and *Wieringen* (20 miles in circumference; population, 1800); *Vlieland* (which consists chiefly of sand hills, and has 620 inhabitants); *Ter-schelling* (14 miles long by $2\frac{1}{2}$ broad; population, 2000, residing in four villages on the south coast, and engaged in fishing), and *Texel*, at the entrance of the *Zuider-zee*.

Texel is separated from the north of the province by the *Mars-diep*; it is 12 miles long, and 6 broad, and has 4920 inhabitants, mostly shepherds and fishermen. The island is famous for its breed of fine-woolled sheep. The northern part of the *Texel* was formerly a distinct island, but has been

joined to the southern part by a sandbank since 1629; it is called *Eierland* or Egg-land, from the great number of gulls' eggs found on it. A portion of the inhabitants are employed in boat-building, and as pilots. The western coast is sheltered by dykes, which were broken through, with great damage to the country, by a storm in February, 1825. The island contains a town and several villages. Off the *Texel*, on 31st July, 1653, the English fleet, under Monk, defeated the Dutch under Van Tromp, who was killed during the action. A lighthouse was erected on the northern island in 1864.

SOUTH HOLLAND has an area of 1176 square miles, and had in 1862, 642,688 inhabitants. It lies S. of the *Haarlem-meer*, and is traversed by the Old Rhine, the *Yssel*, the *Lech*, and by the large branches of the *Maas*, which form the islands of *Voorne*, *Overflackkee*, *Goeree*, *Putten*, *Beveland*, *Ysselmonde*, *Dordrecht*, and *Rozenburg*, W. of *Ysselmonde*. The chief towns are *DELFT*; *DORT*; *HAGUE*; *LEYDEN*; *ROTTERDAM*.

Briel or *Brielle*, a well-built and fortified town, situated on the *Maas*, and on the northern shore of the island of *Voorne*, has a large and commodious harbour, and 4504 inhabitants, many of whom are pilots and fishermen. The name literally signifies a pair of spectacles, and is applied figuratively to it, as the outlook of Holland. It is the birthplace of Admirals Van Tromp and De Witt.

Delftshaven, the port of *Delft*, stands on the right bank of the *Maas*, at the embouchure of the canal that leads to *Delft* and the *Hague*; it is a place of some trade, and has shipbuilding yards, and a population of 3000. Distilling and herring fishing are also carried on here. This town was the nucleus of the Dutch republic; its capture by William de la March, in 1572, having been the first important event in the struggle between Holland and Spain. There are still military magazines here.

Gorkum, a fortified town, on the right bank of the *Maas*, and traversed by the *Linge*, a feeder of the *Maas*, is well built, and has a good trade in horses, corn, fish, agricultural produce, &c. The population numbers 9000; many of them are engaged in the salmon and herring fisheries. A court of primary jurisdiction, a college, and some learned associations have been established in the town.

Gouda, N.E. of *Rotterdam*, on the right bank of the *Yssel* at the point where it is joined by the *Gouw*, is a large fortified town, with a population of 15,000. The town has five churches, hospitals, an orphan house, Latin school, and library, with curious MSS.; very extensive tobacco-pipe factories; brickworks, the clay for the supply of which is taken from the bed of the *Yssel*; rope-walks, gin-distilleries, and breweries. The most important buildings are the town-house and the church, dedicated to St. John, which is famous for its splendid painted windows; both these buildings stand in the great square, in which markets are held. *Gouda* numbers also among its industrial products tobacco, woollen cloth, cordage, and sail-cloth; it is famous as a cheese market.

Helvoetsluis, a small town of 2000 inhabitants, important for its fortifications, its harbour, and large naval dockyards, stands in the isle of *Voorne*, on the right bank of the *Haringvliet* branch of the *Maas*, which separates *Voorne* from *Overflackkee*.

The Prince of Orange sailed from this port for England, November 11, 1688.

Katwyk, N. of the Hague, is a small place famous for the canal and the stupendous dykes and flood-gates executed by the engineer Conrad for Louis Bonaparte in 1809, to assist the Rhine in its struggles to reach the sea.

Maaslandshuis or *Maasshuis*, stands W. of Rotterdam, at the extremity of the canal that enters the Maas opposite the isle of Rozenburg, and has 5000 inhabitants, many of whom are engaged in the herring and whale fisheries. Sailcloth, ropes, leather, and fish oil are the chief industrial products.

Ryswyk, a small village near the Hague, deserves mention as the place where the famous treaty of peace was signed in 1697 between England, France, Holland, Germany, and Spain. The site of the house in which this treaty was concluded is now marked by an obelisk. Population, 2630.

Scheveningen, or *s'Gravenhagen*, on the coast, 2½ miles N.W. of the Hague, is the rendezvous, in the bathing season, of the gay world of that city, to and from which, by a tramway formed by a company, omnibuses frequently ply during the day. The road is through a straight and magnificent avenue of oaks and limes. A favourite mode of visiting the Hague from Scheveningen is by boat on the canal, the banks of which are very picturesque and pleasing, although rather monotonous. The town, in 1861, contained 6100 inhabitants, a splendid bathing establishment, and several well-managed hotels replete with every comfort and convenience.

Schiedam, a well-built town and port, with a good harbour, near the outflow of the Schie into the Maas, has numerous churches, an exchange, a grammar-school, a chamber of commerce, and manufactures, glassworks, rope-walks, building-docks, white lead works, and upwards of 150 distilleries. Schiedam is the chief seat of the manufacture of Dutch gin, commonly called Geneva. The annual produce of that spirit is enormous, and many thousands of pigs are supported by the refuse of the malt used in its manufacture. The inhabitants, many of whom are engaged in the fisheries, in 1861 numbered 15,169.

Schoonhoven, formerly famous for its salmon fishery, stands in a marshy but well-cultivated district, E. of Rotterdam, on the right bank of the Leek, which here forms a good harbour, and receives the Vlist. The population, who manufacture paper and jewellery, numbers 2660.

Vlaardingen, the head quarters of the Dutch herring fishery, for which it fits out annually about seventy boats, stands on the right bank of the Maas. It is a pretty and a well-built town, with a population of 7700.

HOLLAND, NEW. [AUSTRALIA.]

HOLLAND, PHILEMON, was born at Chelmsford in 1551, and educated there and at Trinity College, Cambridge, of which he became a Fellow. Afterwards he was elected master of the Coventry free grammar-school. He is, to the best of our knowledge, the first English translator of Livy, Suetonius, and Plutarch's 'Morals,' and the only English translator of Pliny's 'Natural History,' and Ammianus Marcellinus. He also translated Xenophon's 'Cyropædia,' and Camden's 'Britannia.' In addition to all this, he found time to study and prac-

tise physic, and reached the age of eighty-five, with unclouded faculties.

HOLLAND, SIR NATHANIEL, was the third son of Dance, the architect of the Mansion House, and the younger brother of George Dance, R.A., the architect of Newgate.

Nathaniel Dance was the pupil of Hayman. He was one of the original members of the Royal Academy. He changed his name to Holland upon his acquisition of a baronetcy in 1800, having previously married Mrs. Dummer, who was possessed of entailed estates to the value of 18,000*l.* per annum. Upon his acquisition of his title, Sir Nathaniel Holland appears to have resigned his academical diploma, for from that time he exhibited as an honorary exhibitor. He represented for some time the borough of East Grinstead: he resided at Cranbury House, near Winchester, and he died suddenly in that city, October 15, 1811, aged about sixty-eight. All his best works are chiefly in private collections. Orpheus, and Garrick as Richard III., are two of his best efforts.

HOLLAND, HENRY, held a high rank among the architects of his own time, and was greatly patronized by George IV. when prince of Wales. But we have no information as to his personal history. His finest work was the portico of Carlton House. The Pavilion at Brighton was built by him, but was transformed into its present shape by Nash. Drury-Lane Theatre, which was burnt down in February 1809, was erected by Holland, and he was also the architect of the India House. He died at his house in Hans Place, June 17, 1806, aged about sixty.

HOLLAND, HENRY RICHARD VASSAL FOX, LORD, was the only son of Stephen, second Lord Holland. His mother was Mary, daughter of John Fitzpatrick, first earl of Upper Ossory. He was born at Winterslow House, Wilts, November 21, 1773. He succeeded to the peerage when he was little more than a twelvemonth old. He was educated at Eton, and at Christ Church, Oxford, where he took the honorary degree of M.A., in right of his rank, in June, 1792.

It was in the course of a continental tour, that at Florence, in the beginning of the year 1795, he first met Lady Webster, the wife of Sir Godfrey Webster, with whom he returned to England in June 1796, and whom he married the next year, after she had been divorced from her first husband, who obtained 6000*l.* damages in an action against Lord Holland. After his marriage with Lady Webster, Lord Holland assumed, by sign-manual, her family name of Vassal, which, however, has been laid aside by his children.

He now took his place in the House of Lords. His first speech was made on the 9th of January, 1798. From this date Lord Holland took a frequent part in the debates for the next four years, being all this time one of the steadiest opponents of the administration, and seconding in the Upper House the principal efforts of his uncle Charles James Fox in the Commons.

On August 28, 1806, Lord Holland and Lord Auckland were appointed joint-commissioners for arranging the several matters in discussion between this country and the United States, with Mr. Munro and Mr. Pinckney, the United States' commissioners; and on the 27th of the same month he was sworn of

the privy council. An arrangement of the differences with America was effected after a long negotiation, but Mr. Jefferson refused his ratification, and it came to nothing. On October 15, after the death of Mr. Fox, Lord Holland was appointed lord privy seal; and he held that office for the six months longer that the Grenville ministry lasted.

In 1806, Lord Holland published 'Some Account of the 'Life and Writings of Lope Felix de Vega Carpio,' and followed it up next year with 'Three Comedies from the Spanish,' and in 1808 he edited and introduced by a preface Mr. Fox's fragment entitled 'A History of the early part of the Reign of James the Second.'

On the accession of the Whigs to power in November, 1830, he became once more a cabinet minister as chancellor of the duchy of Lancaster; and this office he held (with the exception of the ministerial interregnum of a fortnight in May, 1832, and Sir Robert Peel's four months' tenure of power from December 1834 to April 1835) till his death at Holland House on the 22nd of October, 1840. He was succeeded by his son.

HOLLAR, WENCESLAUS, was born at Prague, in Bohemia, in 1607. He was first intended for the profession of the law, but abandoned it for art. He was only eighteen when his first specimens appeared. These were a print of the 'Ecce Homo,' and another of the Virgin, with a Virgin and a Christ after Albert Dürer, with Greek verses at the bottom of the plate, executed in 1625. He removed from Prague in 1627. His views along the Rhine, the Danube, and the Neckar gained him his greatest reputation. In 1636, Howard, earl of Arundel, met with Hollar when proceeding on his embassy to Ferdinand II., and took him into his retinue. Hollar attended him to the emperor's court, and made several drawings and prints of the places through which they travelled. Lord Arundel brought Hollar to England, where he painted portraits of the royal family, and executed other subjects, of which his view of Greenwich, dated 1637, was one of the first. On the breaking out of the civil war, he experienced some vicissitudes of fortune, but eventually joined Lord Arundel at Antwerp, where he remained for several years. In 1652 he returned to England, and worked incessantly till the time of his death. The plates by him in the first and second volumes of the old edition of Dugdale's 'Monasticon,' in Dugdale's 'History of St. Paul's,' and in his 'Survey of Warwickshire,' sufficiently prove his industry. He died in London, March 28, 1677. His works, according to Vertue's catalogue of them, amount to nearly 2400 prints.

HOLLY. [LEX.]

HOLLYHOCK. [ALTHEA.]

HOLMAN, JAMES, a lieutenant in the navy, and generally known as the Blind Traveller, was born in 1787. He had the misfortune to lose his sight at the age of twenty-five, and in 1812 was appointed one of the naval knights of Windsor. When he had become accustomed to the deprivation of sight, he determined, for the purpose of amusing his mind, to undertake a journey through Europe. Accordingly he undertook a tour in 1819-21 through France, Italy, Savoy, Switzerland, and various parts of northern Germany. His travels were published, and found replete with many amusing incidents and

observations. In 1822 he undertook a voyage to St. Petersburg, and thence proceeded to Moscow, Novgorod, and Irkutsk in Siberia; but here he received an imperative order from the emperor, by which he was obliged to return. He afterwards undertook a series of voyages and travels round the world, comprehending Africa, Asia, Australia, America, &c., which were subsequently published. From South America he crossed to the Cape of Good Hope, and visited in succession Madagascar, Ceylon, Hindustan, New South Wales, Van Diemen's Land, and New Zealand. In 1843 he went to the Adriatic, and there visited Bosnia, Servia, Dalmatia, Montenegro, and other places. His series of voyages and travels excited much interest when published; but they can never be considered as reliable authorities. He died in 1857.

HOLMSUND, a small port in the Baltic belonging to Sweden.

HOLOCANTHUS (Gr. *holos*, 'entire,' and *acantha*, 'a spine,'), a genus of fishes, of the family *Chaetodonidae*, in which the pectoral and ventral fins are pointed, and the operculum armed with a strong spine at its lower angle.

HOLOCAUST (Gr. *ὅλος* 'the whole,' and *καυστός*, 'burnt'), among the classical ancients, a religious sacrifice, in which the whole instead of a portion of the victim was burnt as an offering to the gods. The custom was not dissimilar to the burnt-offering of the ancient Jews, which consisted of a bullock without blemish brought to the tabernacle of the congregation. But at the Feast of Tabernacles, during the eight days' festival, the Jews offered seventy bullocks, &c.

HOLOCENTRINÆ (Gr. *holos*, 'entire,' and *centron*, 'a spur'), a family of the *Percidæ* or *Perches*, in which the bodies are covered with sharp rough scales, or thorn-like plates, and the head is very spiny.

HOLOGRAPH, a deed or testament written wholly by the testator's own hand. By the law of England it does not matter whose penmanship is used in the making of a will or deed, provided the document be properly signed and attested; but in Scotland there is a distinction made between holograph and other deeds. For instance, no witnesses are required to attest holograph deeds or testaments. If the handwriting is disputed, evidence must be given as to whose it is.

HOLOLEPTA (Gr. *holos*, 'whole,' and *leptos*, 'thin'), a genus of coleopterous insects, of the family *Clavicornes*.

HOLOPTYCHUS (Gr. *holos*, 'whole,' and *ptyx*, 'a fold'), a genus of fossil ganoid fishes found in the coal formation. The scales of this singular animal resemble those of reptiles, and present a wrinkled appearance. 'There is nearly a perfect specimen,' says Professor Ansted, 'measuring as much as thirty inches long without the tail, and the proportions are singularly massive. The head is small; but the unclothed jaws, covered with hard enamel instead of skin, are lined with a double row of teeth; the outer range thickly set, and fringing the enamelled edge of the mouth; the inner ones wider apart, and more than twenty times as large.'

HOLOSTEUM, a genus of plants belonging to the natural order *Caryophyllææ*, and the sub-order

Alsineæ. The species of this genus are herbs with nothing to recommend them for use or cultivation. One species, *H. umbellatum*, is British. It is not a common plant, but has been found on old walls and dry places at Norwich, Bury St. Edmund's, Eye, and Yarmouth.

HOLOTHURIA (*Holothuria Family*), a race of marine animals whose particular organization is not yet fully elaborated. Cuvier places the *Holothuria* under his *Echinodermes Pédicellés*, and M. De Blainville assigns them a situation within the pale of his *Echinodermata*.

For a sketch of the anatomy of these singular beings see Cuvier ('Règne Animal,' vol. iii. p. 238). The *Holothuria* are divided into many genera very indefinitely determined.

According to M. Delle Chiaje, certain species of *Holothuria* are eaten by the poor inhabitants of the Neapolitan coast; but the Chinese regard these Sea Cucumbers, as they are called from their shape, as delicacies. Whole fleets of Malay proas visit the south coast of Australia, the north coast of Ceylon, and the west coast of New Guinea, for the purpose of procuring and salting these sluglike animals. The cargo is generally carried to Timor or Macassar, and sold to the Chinese, who meet the vessels on their return from their fishing. These animals are known under the name of Tripang and Biche de Mer. In the market of Macassar, the great staple of this fishery, not less than thirty varieties are distinguished, varying greatly in price, according to the estimation in which they are held. The ordinary size of the slug is about a span in length and two or three inches in girth, but some specimens reach nearly two feet in length and seven or eight inches in circumference.

HOLSTEIN. [SCHLESWIG and HOLSTEIN.]

HOLSTENIUS, the Latinized name of L. HOLSTE, born at Hamburg in 1595, became one of the first scholars of his time. At Paris he embraced the Roman Catholic religion. He accompanied Cardinal Barberini, the nephew of Urban VIII., to Rome in 1627. From that time he lived in the cardinal's house, was made canon of St. Peter's, and lastly librarian of the Vatican. He was sent on several missions to Germany, among others to Innspruck, to receive the abjuration of Queen Christina of Sweden. Holstenius died at Rome in February, 1661. He had collected a vast quantity of scarce books and MSS., and he left many works of his own in an unfinished state. His published works are numerous, and some of them are valuable.

HOLSWORTHY. [DEVONSHIRE.]

HOLT. [DENBIGHSHIRE.]

HOLT, SIR JOHN, lord-chief-justice of the King's Bench, was the eldest son of Sir Thomas Holt, Knt., a bencher of Gray's Inn, and a gentleman of property in Oxfordshire. Sir John was born at Thame in Oxfordshire, December 30, 1642, and was in his sixteenth year entered as a gentleman commoner at Oriel College, Oxford. His college life appears to have been unusually wild and licentious. In 1652, before he was ten years old, he had been entered upon the books of the Society of Gray's Inn, and on the 27th February, 1663, was called to the bar, and rose rapidly into notice as a first-rate lawyer and successful advocate. He was employed in most of

the state trials which the troubled times in which he lived produced, and was generally counsel on behalf of the accused. His opposition to the measures of the court brought upon him the vengeance of James II., who procured his removal from the recordership of London. Shortly after the accession of William III. (April, 1689), Sir John Holt was made lord-chief-justice of the King's Bench, in which situation he continued during the remainder of his life, although the chancellorship was offered to him on the removal of Lord Somers in 1700. Sir John Holt died in March, 1709-10, leaving behind him a high reputation for learning, honour, and integrity.

HOLY ALLIANCE, a league formed among certain of the principal sovereigns of Europe, after the defeat of Napoleon at Waterloo, on the proposal, it is said, of the Emperor Alexander of Russia. It arose from the religious feeling then prevalent of deliverance from French domination, which was considered as a consequence of the French Revolution, and Napoleon as an incarnation of evil. The act of this Alliance is reported to have been sent by Alexander, in his own handwriting, to the emperor of Austria and the king of Prussia, and signed by them. It consisted of a declaration, that in accordance with the precepts of the gospel, the principles of justice, charity, and peace should be the basis of their internal administration and of their international relations, and that the happiness and religious welfare of their subjects should be their great object. All the European sovereigns finally became members of the Holy Alliance, and it soon transpired that this Alliance was connected with the determination of those sovereigns to support existing governments throughout Europe by the declaration of November, 1819, and to check the liberal spirit then breaking out all over the continent. Afterwards, the congresses of Troppau, Laybach, and Verona established the character of the Alliance, to which the war of France, or rather of the Bourbons, against Spain in 1823 gave additional illustration. Since the secession of England and France, the Alliance can scarcely be said to have any active existence.

HOLY COAT OF TREVES, a garment, the pretended seamless coat of our Saviour, which is carefully preserved in the cathedral of Treves. It is supposed to have been discovered in the fourth century, and afterwards concealed till 1196, in which year, and again in 1512, it was publicly exhibited. It has been shown as recently as 1810 and 1844, when multitudes flocked to see it, and to take part in the religious festival of which it was made the occasion.

HOLY ISLAND. [DURHAM.]

HOLY LAND. [PALESTINE.]

HOLY OFFICE. [INQUISITION, THE.]

HOLY ORDERS. [ORDINATION.]

HOLY PLACES and **SEPULCHRE.** [JERUSALEM.]

HOLY WATER is water blessed by a bishop or priest for certain religious uses in the Roman Catholic, Greek, Russian, and Oriental Churches, but regarded by Protestants as unscriptural and superstitious. By the ancient Jewish law, the hands and face had to be sprinkled with water before entering the sanctuary, and the practice was retained in the early Christian church. The use of holy water is

regarded as symbolic of the purity that should reign within, and is believed to derive a special fitness for this purpose from its blessing by the priest.

HOLY WEEK, called also Passion Week, is the week before Easter, commencing on Palm Sunday, and comprising Holy Thursday, Good Friday, and Holy Saturday. It is commemorative of the passion of Jesus Christ during the week previous to his resurrection. Many Protestants observe only the Friday [GOOD FRIDAY] as a solemn day; but in the Roman Catholic Church the whole week is made one of great solemnity and fasting. They, however, call this Holy Week, and the preceding one Passion Week. Holy Week is not observed by Presbyterians.

HOLYHEAD. [MENAI STRAIT.]

HOLYHEAD ISLAND, a small island of North Wales, on the western side of Anglesea, from which it is separated by a sandy strait, fordable at low water. Its greatest length is seven, and its breadth three and a half miles. It has an area of 7000 acres, and a population of 8868. The island has some good pasture and arable land, but is mostly rocky and barren; the northern coast especially being very wild, and marked with precipices and caverns haunted by innumerable sea-fowl, while the falcon eagle soars over the highest crags. On the north-west coast are two islets, named respectively North and South Stack, on which there are lighthouses, with revolving lights visible 20 miles distant. South Stack is connected with Holyhead Island by a suspension bridge. *Holyhead*, a seaport and market town, is situated on the island of Holyhead, and is 270 miles north-west of London, with which it is in direct communication by railway. It is the government steam-packet station for Dublin, from which it is distant about 70 miles. At great national cost the harbour has been improved, and by the construction of a huge pier or breakwater, 900 feet long, the exposed bay has been converted into a secure roadstead, available for vessels of the largest class, in all winds, and at all states of the tide. The harbour of refuge just (1866) completed, incloses an area of more than 300 acres, with a depth of six fathoms. The population of Holyhead in 1861 was 6190, chiefly employed in the coasting trade, in shipbuilding, and rope-making. The town unites with Amlwch, Beaumaris, and Llangefin in sending a member to the House of Commons.

HOLYROOD, on the eastern side of Edinburgh, was anciently the residence of the Scottish sovereigns, and the scene of many tragical events connected with their history. Its site is a small plain or valley between the Calton Hill, a rounded summit rising 355 feet above the sea level, and the majestic Arthur's Seat, rising to the height of 822 feet, one of the most delightful resorts in the vicinity of Edinburgh. It was an abbey, founded by King David I. of Scotland in 1128, and dedicated in honour of the Holy Cross or Rood brought from Jerusalem by St. Margaret in 1070, which became one of the heirlooms of Scotland. The abbey was burned by the English in 1385, in 1544, and in 1547. It was made a chapel-royal in 1672. During the revolution of 1688 it was plundered and partially burned, and remained in a dilapidated state till 1758, when it was repaired and roofed.

In the year 1295 a Parliament was held in the

abbey by John Balliol. James II. was born in it, and made it his home. James IV. laid the foundations of a palace in addition to the abbey, and Holyrood became the chief seat of the Scottish sovereigns. Queen Mary resided here, and it was in this palace, in 1566, that Rizzio was murdered. James VI. was born and lived in it until his accession to the throne of England, and visited it afterwards. Charles II. rebuilt it, and various royal personages occupied it till 1822, when George IV. held his court there, and it has been repeatedly visited by her majesty Queen Victoria.

The precincts of Holyrood are a sanctuary for Scotch debtors, where they may avoid imprisonment by residing within them. A certificate of protection is given by an official within twenty-four hours of the debtor taking refuge. The practice is considered somewhat disreputable, and is not resorted to so much as formerly.

The castle of Holyrood contains the crown and regalia of Scotland, an armoury, and barracks.

HOLYWELL. [FLINTSHIRE.]

HOLZER, JOHANN, a fresco painter, was born at Burgeis, in the Tyrol, in 1709. His father was miller to the Benedictine convent of Marienberg, and Holzer was first instructed by N. Auer, at Meran in the Tyrol. He made here such progress, that at the age of eighteen he was invited by the painter J. A. Merz to Straubing in Bavaria, to assist him in some frescoes in the convent church of Oberalteich. From Straubing Holzer went to Augsburg, where he lived six years in the house of the painter J. G. Bergmiller. Holzer painted many excellent frescoes upon the exteriors of houses in Augsburg, but few, if any, now remain; there is, however, a collection of twenty-eight prints after them by J. E. Nilson, entitled 'Picturæ a Fresco in ædibus Augustæ Vind., a J. Holzer,' &c. Holzer's greatest works are the frescoes of the convent church of Schwarzach near Würzburg. They are now in a dilapidated condition. Holzer died of a fever at Clemenswerth, in July, 1740, at the age of thirty.

HOLZMINDEN. [BRUNSWICK.]

HOMAGE, an incident of tenure which is now abolished by 12 Car. II. c. 21. The word is derived from *homo*, because when the tenant did his service to the lord, he said, 'I become your man,' &c. (Litt. s. 85.) The copyholders, or tenants who attend to do their duty in a court baron, are called the *homage*.

HOMALIA'CEÆ, a small natural order of shrubby exogenous plants with polypetalous flowers. The species chiefly inhabit tropical countries; they have small starry flowers, and are of no known utility. Brown considers them nearly related to *Passifloraceæ*.

HOMARUS. M. Milne-Edwards separates the true marine lobsters from the fluviatile craw-fishes under the title of *Homarus*, reserving to the latter the title of *Astacus*. He regards the genera *Astacus*, *Homarus*, and *Nephrops* as constituting the family of the Astacians. [ASTACUS.] Fossil impressions of Astacians have been described by various writers.

HOMBURG. [HESSE-HOMBURG.]

HOME, or HUME, JOHN, was born in Scotland about the year 1722, and is supposed to have been a relation of David Hume. He was bred to the ministry of the Church of Scotland, and settled in

the parish of Athelstaneford, where he produced his tragedy of 'Douglas,' which was acted at Edinburgh with the most unbounded applause. Four other tragedies followed, but they have been long since forgotten. Home died in 1808.

HOMER (in Greek, *Homéros*), the supposed author of the earliest Greek heroic poems extant, and of some hymns in praise of different gods. Opinions the most various have been held regarding his birthplace, his age, his station, and the circumstances of his life. The author or authors of the 'Iliad' appear from the work to have been accurately acquainted with the geography of Greece and the northern part of the Archipelago; and it has been inferred that Homer was a wandering minstrel. The existence of such wandering minstrels seems to be shown by the Hymn to Apollo, quoted by Thucydides; as the notices of Phemius and Demódocus, in the Homeric poems, prove the existence of bards attached to particular courts.

The poems attributed to Homer are the *Iliad* and the *Odyssey*, to which some have added the Homeric Hymns. Of these poems, the *Iliad* stands first, as the oldest and at the same time the completest specimen of a national heroic poem. The subject is the revenge which Achilles took on Agamemnon for depriving him of his mistress Briseis, during the siege of Troy, and the consequent evils which befell the Greeks. It is divided into twenty-four rhapsodies or books, which detail the history of the besieging force during the period of Achilles' anger, and end with the death of Hector (who is slain by Achilles in retaliation for Hector's having killed Patroclus), and the solemn burial of the Trojan warrior. Heroic poetry, as a simple form of art, does not imply the development of a plot, but rather the extraction of a certain portion from the poetical annals of a nation, beginning and ending just where the subject may seem to suggest, but not necessarily ending with a regular disengagement of a plot regularly worked up and studiously combined from the beginning of the poem. Whether what we now possess be the exact poem which thus forms the beginning of all Greek literature, is scarcely doubtful. The lapse of so many ages can hardly have failed to have introduced some passages, and to have altered and removed others.

The *Odyssey* can hardly be called a national epic. It is much nearer the romance of chivalry than any other ancient work now in existence. It contains the account of those adventures which Ulysses (*Odysseus*) encountered on his way home from Troy, and in its present state consists of twenty-four books, which division is said to be owing to the grammarians in the time of the Ptolemies. There is little doubt that much has been interpolated in the account of Ulysses' visit to the shades, and Aristophanes and Aristarchus the grammarians considered the latter part of the 23rd and all the 24th book spurious. A characteristic of the *Odyssey* to which we have just alluded, is its romantic look, using romantic as opposed to classical. There is something quite northern in the adventures of Ulysses; they might have happened to a knight of Arthur's court, or perhaps still better to Beowulf. The Sirens would be singing maidens, who decoy travellers by their strains; the nymph Calypso would find an antitype in some

enchantress. Ulysses slays the suitors much in the way of William of Clonsdesley in the old ballad.

The difference in the character of the *Iliad* and *Odyssey* might lead us to the conclusion that these poems are not the product of the same mind. Other differences, however, of less importance have been pointed out by the critics. How far either poem can claim a single author is a still more difficult question. There is an historical fact which has been adduced in support of one side of this question, namely, the existence of a race of men called Rhapsodists, or *Homeridæ*, who imitated Homer, enlarged upon him, and interpolated his poems with verses of their own (Hermann, 'Preface to Homer's Hymns,' p. 7); treating him very much as the Bible was treated by one school of the early Mystery-mongers. Now those who deny the unity of the *Iliad* assert that these Rhapsodists manufactured it among themselves, until it gradually assumed that form in which Pisistratus finally established it, and in which we now have it. Whatever truth there may be in this opinion or any other as to the Homeric poems, we must admit that many lines and even whole passages may be interpolations. The Hymns, Epigrams, and the 'Battle of the Frogs and Mice,' make up the sum of the Homeric poems, genuine and spurious. The earliest mention made of Homer is by Pindar. Herodotus and Thucydides quote and refer to him; and by Plato he is constantly either hinted at or transcribed.

The principal modern editions of Homer are those by Clarke, Payne Knight, and Mr. Gladstone, in this country (the second having the digammas inserted in what the editor supposes to be their proper places), and abroad, Heyne, Hermann, and Nitzsch, for the *Iliad*, Hymns, and *Odyssey* respectively. Of translations, we have Hobbes, Chapman, Pope, Cowper, Sotheby, Worsley, and Lord Derby. Although the *Odyssey* of Worsley (Blackwood, 1861), has received special marks of public approbation, perhaps, on the whole, Lord Derby's is the best. The German translation by Voss is wonderful as regards accuracy. It is in hexameters, and preserves every sentence, and nearly every word. In Italian the translations of Cesarotti and Monti, and in French that of Montbel, are the best known. (See Plate 'Homer.')

HOMESTEAD. There is in most districts of the country a great difference between what is required as farm buildings by the intelligent farmer, and what is supplied to him by the landowner. Every writer on agriculture has described what is wanted, but it is only here and there that specimens are found which come up to their ideal. The cost of good buildings is well repaid by the increased annual value of the estate. Shelter for live stock, and safety for produce, and for both cattle and implements, are always worth paying for. The tendency at present is to do away with barns, and to cover a given space of ground with shedding, dividing it out into yards, stalls, or boxes, according to convenience; but it is still necessary to make a careful selection of the position, aspect, accommodation, and supply of water for the homestead buildings. The following description of the Englefield farmery in Berkshire will give an idea of the modern first-class homestead. The buildings are centrally placed. They consist, first, of a block about 50 feet by 100 feet, covered in by a double span roof, under which are forty-two

boxes—six single rows of seven each—the rows being separated alternately by three narrow gangways for feeding, and two wider gangways for carts entering to remove the dung. Each box has a manger for roots and hay, and a trough for water. Another block of buildings of the same length includes thrashing machines, granary, root house, chaff house, steam house, and steam power (a fixed 10-horse engine, consuming eight cwt. of coal a day, and worked on an average three days a week). Between the two the space is roofed over and occupied as a straw house. The steam power is conveyed by a strap to a longitudinal shaft up stairs, from which straps on pulleys carry it to the thrashing machine, turnip-cutter, two pairs of millstones, two chaff-cutters, cake-crusher, and corn-bruiser. The steam power is used to cut the roots for two days' supply, by means of Samuelson's largest Banbury cutter, to cut hay chaff at the rate of five tons a day, and to crush oats and crack beans—all at one and the same time.

On the south side of this block of cattle boxes is a shed for implements. On the west side is a range of stables, lofty and airy, with no particular nicety, but great convenience of internal arrangement, and on the other side, as a lean-to, are shedding and yards for the calves, of which fifty or sixty are kept in three divisions, provided with racks for straw and mangers for the roots, chaff, and cake. North of the thrashing machinery and barns are six long rows of open roofing for storing away the corn. The implement shed, barns, straw house, granaries, and corn shed thus succeed one another as you go northwards. East of this range are nag stalls, slaughter houses, poultry house, cow byre, &c., on two sides of a square, thus sheltering a yard for cows and calves from the north and east, and lying alongside of the cattle boxes, and another square of pigsties and yards lying alongside of the granaries and thrashing machinery. The corresponding space eastward of the rows of corn sheds is occupied by sheds and yards for cows when required. The buildings were planned by Mr. Benyon, M.P., on whose farm they are, and erected by the workmen of the estate at a cost of about 3000*l*.

HOMICIDE. [MURDER.]

HOMILY (ὁμιλία), in ecclesiastical matters, is a familiar discourse on a religious subject. In the earliest ages of the church the words *sermon* (λόγος) and homily appear to have been used indifferently.

All the homilies of the Greek and Latin fathers were composed by bishops, for before the fifth century none but bishops were allowed to preach. In modern use the term 'homily' is applied to a discourse read out of a book, and not composed by the preacher. At the period of the Reformation in England two books of homilies were published by authority, in order to insure uniformity of doctrine in the Church of England. The first book, ascribed to Cranmer, appeared in 1547; the latter, said to be by Jewell, in 1563. They were originally meant to be read, in default of regular sermons, in such remote or poor localities as had no regular clergyman, and to avoid heterodoxy.

HOMŒOPATHY (a Greek word, ὁμοιοπάθεια, literally 'similar or like state of feeling'), a mode of treating diseases, founded on peculiar doctrines, which were first proposed in 1796 by Samuel Hahnemann,

a German physician. [HAHNEMANN.] The homœopathic method consists in the administration of a medicine which is capable of exciting in healthy persons effects closely similar to the symptoms of the disease which it is desired to cure.

This system of medicine stands in direct contradistinction to that founded upon the principle of treating diseases by their opposites, *contraria contrariis curantur*, which has served more or less as a guiding law since the time of Galen. To this last method the homœopaths have given the name Allopathy, from two Greek words signifying 'other suffering.' The arguments adduced in support of the truth of the homœopathic law seem to be principally drawn from the three following sources:—

1st. Popular experience, it is said, has proved that the safest manner of restoring the circulation of a frozen limb is to rub it with snow (*similia similibus curantur*). Warm applications, according to the evidences of the same experience, would cause the destruction of the part affected.

Again, severe burns are most quickly cured by the use of heated spirits of wine or oil of turpentine, which excite a very similar sensation, although in a greatly modified degree. Cold applications, although they give temporary relief, are, as is well known, generally followed by increased inflammation and severe after-suffering.

The homœopaths also insist that the acknowledged efficacy of Jenner's great discovery is a powerful argument in favour of the truth of the homœopathic law, since by producing a similar disease an almost perfect immunity from attacks of the small-pox is obtained. The same principle is exhibited in morals—'Weep with them that weep, and rejoice with them that rejoice.'

2ndly. The homœopaths endeavour to show by a number of observations collected from the works of different medical authors, that many drugs recorded by these authors as curative in different forms of disease, were observed by others to produce effects closely resembling the symptoms of those very forms of disease, or that they acted upon the principle *similia similibus*.

3rdly. Hahnemann, it is said, was first struck with the close analogy between the effects produced by Peruvian bark and the symptoms of that form of ague for which it was considered a specific. He having obtained similar results in connection with other medicines tried upon his own person, was led to the discovery of the homœopathic law; and he, believing that the mode of operation of all remedial agents was in perfect harmony with this principle, by repeated experiments upon himself and some medical friends converted to his opinions, first determined their direct action and then employed them in disease. The practical results obtained by him and the physicians of his school are appealed to by them as a further confirmation of the truth of their fundamental law; and it is well to note that Hahnemann taught a view almost as important as that embodied in his law—the view that it is possible to learn the *pure* effects of medicines only by trying the medicines on the healthy.

The extremely minute quantities in which the remedies are administered seem to form a marked difference between the homœopathic and all other

schools of medicine. The homœopaths, however, assert that this is merely a point of practice to be determined by the physician at the bedside of his patient, and that, in the application of the homœopathic principle to the treatment of disease, it was soon found that remedial agents, given in the doses usually employed, acted too energetically upon a frame already predisposed to their influence by the affinity existing between their medicinal effects and the morbid signs of the disease; and hence a gradual diminution was made in the quantity of the medicine exhibited, in order to approximate to that amount which might exert its full curative power without aggravating the sufferings of the patient by an excess of medicinal action. The result has been the general adoption among homœopaths of the minute dose at present in use, which perhaps more than any other single cause, from its discrepancy with generally received opinions, has prevented any impartial investigation into the principles of the system by the profession at large. Hahnemann, however, taught that the efficacy of these medicines in these infinitesimal quantities rested, first, on the application being in accordance with the homœopathic law; and second, because the powers of the medicines are developed (Hahnemann termed it *dynamized*) by the process of preparation—a process which Hahnemann invented. Indeed, the whole has been well summed up in the following statement, which the editor of *Household Words* inserted:—We have never been subjects of the homœopathic mode of treatment, nor have we ever been concerned in making others so. But as we desire to state the homœopathic doctrine fairly, like all other doctrines to which we make any reference, and as it has been suggested to us that we may have scarcely done so in a passing allusion to it at page 592 of the last volume of this journal, we will here reprint the following extract from a work in explanation of homœopathic principles by Dr. Epps:—‘It is not maintained that a millionth part of a grain or of a drop (to take a given though a large quantity in homœopathic administration), will produce any visible action on the man in health; nor is it maintained that a millionth part of a grain or of a drop will act on the man in disease; but it is maintained that the millionth part of a grain or of a drop will act on the man in disease, if between the diseased state of the man and the medicine, infinitesimally administered, there is a homœopathic relationship. In other words, the homœopaths do not vaguely say that medicines in infinitesimal doses cure diseases; but they do say that medicines given for the cure of diseases to which they are homœopathic, do cure these diseases when administered in infinitesimal quantities: to repeat, the homœopathist, in maintaining the efficacy of medicines in infinitesimal quantities, regards three requirements as necessary:—First, the development of virtues in medicines by the process of preparation; second, the increased receptivity to impression produced by disease; and third, the selection of the right remedy.’—(‘Homœopathy and its Principles Explained,’ by John Epps, M.D.)

It now numbers in its ranks some medical men who had obtained high repute and professional eminence in the other systems before they embraced the principles of homœopathy, and seems to be

more or less diffused in all parts of the world. In America there are upwards of 2000 avowed practitioners of the system, and about 300 in Great Britain. The great bulk of the medical profession in England are, however, more or less opposed to its adoption, owing in a great measure to the fact, that with increased knowledge of disease and the action of medicines, there has been a tendency to discard all general theories with regard to both.

HOMOGENEOUS, HETEROGENEOUS, are terms applied in mathematical language to expressions which have or have not the same number of factors of a given sort in each term. Thus, with respect to x and y , $ax^2 + by + cx^2$ is homogeneous, but $ax^2 + by$ is heterogeneous.

HOMOLA, *Homola Tribe*. The Homolians, according to the system of M. Milne-Edwards, constitute a group of the anomurous crustaceans, including the genera *Homola*, *Lithodes*, and *Lomis*; genera which he regards as closely related to each other, although previous naturalists had placed them widely asunder. Of the habits and manners of these small crustaceans nothing is known.

HOMOLOGOUS, a term applied in Euclid to those magnitudes which, being of the same kind, occupy different places in a proportion, one being an extreme, and the other a mean.

HOMOLOGY (Anatomy), a term derived from the Greek, *homos*, ‘like,’ and *logos*, ‘a discourse.’ It is often popularly used as if it were the same as *analogy*. But this is not correct. Homology is the relation between organs or parts of the body which are constructed on the same plan, however much they may vary in form, or serve for different uses. Thus, there is a homology between the arm of man, the fore legs of the horse, the wings of birds, and the pectoral fins of the cod, because, though used for different ends, they are constructed on the same plan—but there is no analogy. On the other hand, there is an analogy between the wings of the butterfly and those of birds, because both serve for flight.

HOMOLONOTUS, the name of a group of Trilobites, in which the tripartite character of the dorsal crust is almost lost; for which reason Mr. Miller called it Monolobite. *Homolonotus Knightii* occurs in the Upper Silurian rocks of England, and a similar species at the Cape of Good Hope.

HOMOIOUSIAN and HOMOIOUSIAN. It is scarcely possible to exaggerate the importance which was attached to the difference of the above words in the early church, although, as will be seen, it consists only of a single letter. The first signifies ‘the same substance,’ and the second ‘like substance.’ The former was the watchword of orthodoxy in the celebrated Arian controversy and at the Council of Nice, which declared the Son to be of the same substance as the Father. The Arians, on the other hand, held the subordination of the Son, and proposed to substitute *homoiousian*, i.e., a similar but not identical substance. The words distracted the church for many years.

HOMOPTERA, one of the sections into which the class *Insecta* is divided. According to Leach, Stephens, and some other authors, the section *Homoptera* is regarded as an order; but in Latreille’s arrangement it forms the second of the two great sections into which the order *Hemiptera* is divided.

The insects of this group are thus characterized by Latreille:—Rostrum arising from the lowest part of the head near the chest; the elytra, almost always tectiform, are of the same consistence throughout, semi-membranous, and sometimes resembling the wings; the three segments of the thorax are blended, and the first is often shorter than the following.

In the typical *Homoptera* the head is large, broader than long; the eyes are large, and there are ocelli, or simple eyes, between them; the antennæ are minute, composed of but few joints, and terminated by a seta; the rostrum is a slender-jointed process, which, like that of the Hemiptera, lies close to the chest; the legs are of moderate size; the hinder tibiæ are usually spined; the body is convex above and flattish beneath; the wings are semi-membranous, the anterior pair often opaque, sometimes transparent, and always of a uniform texture throughout. The larvæ are active and resemble the perfect insect, excepting that they possess no wings; the pupæ are also active, but possess rudimentary wings.

These insects feed upon vegetable juices. The females are furnished with an ovipositor, composed of three denticulated blade-like processes, which are lodged in a groove in the abdomen. By means of this ovipositor they pierce holes in vegetables, in which they deposit their eggs. Many homopterous insects possess the power of leaping by means of their posterior pair of legs.

The section or order *Homoptera* may be divided into the following families, most of which are analogous to Linnæan genera, or nearly so.

1, *Cicadidæ* (Leach); 2, *Fulgoridæ* (Stephens); 3, *Cercopidæ* (Leach); 4, *Psyllidæ* (Stephens); 5, *Thripidæ* (Stephens); 6, *Aphidæ* (Leach); 7, *Coccidæ* (Leach). The first two families constitute the section *Cicadariæ* of the 'Règne Animal.' [FULGORA.] The other references are *CICADELLA*, *APHIS*, *GALLINSECTA*.

HONAN, an island province of China, mostly between lat. 32° and 37° North, and long 110° to 116° East. The area is stated to be 65,104 square miles, and the population 29,669,771. Its northern part is intersected by the Hoang-ho, and all its streams are affluents of that river. It is considered the most fertile and salubrious province in China, and was the seat of government for many centuries, when it was named Chung-wha, or *Central Flower*, and hence the title of 'Central Flowery Land' applied to the whole country.

HONAWAR, a seaport town of British India, in the presidency of Madras, 200 miles N.W. of Seringapatam, containing a population of about 12,000. It is the chief of a subdivision, and is a civil and detachment station. Hyder Ali here formed a dock for building ships of war, some of which were destroyed by the British in 1798. The place stands on the north side of an extensive inlet of the sea, or salt water lake, 3 miles broad, and 7 long, which contains several islands.

HONDEKOETER, the name of a celebrated family of Dutch painters, whose founder, Egidius Hondekoeter, born at Utrecht in 1583, was the son of a marquis of Westerloo, a wealthy landowner in Brazil. He painted chiefly landscapes, and he died at Amsterdam. His son *Gijsbert*, born in 1613, painted landscapes in the manner of his father. He

died at Utrecht in 1653. *Melchior Hondekoeter*, son of Gijsbert, born in 1636, was the most distinguished of the family. He painted poultry with admirable skill. His pictures are held in high estimation, and fetch great prices. He died in 1695.

HONDURAS, a republic of Central America, situated in lat. 13° to 16° N., and 85° to 89° W. It is bounded on the north and east by the Caribbean Sea and Mosquitia; west, by Guatemala; south, by Salvador and the Bay of Comayagua on the Pacific; and south-east, by Mosquitia and Nicaragua. The state is divided into seven departments, named after their principal towns, of which Comayagua is the capital. Of the ports, the chief are Truxillo, on the Caribbean Sea, and Port San Lorenzo, in the Bay of Comayagua. The republic consists of a senate of fourteen members, a legislative chamber of fourteen deputies, and a president elected by the two chambers. The population at the last census was estimated at 308,000. [CENTRAL AMERICA.]

HONE, WILLIAM, was born in 1779, at Bath, where his father is stated to have been an occasional preacher among the dissenters. After being engaged for some years as an attorney's clerk at Chatham and in London, William quitted the law, and having married, set up in July, 1800, as a bookseller in Lambeth, and afterwards in three or four other places in London, in all of which he was unsuccessful. In 1811 he took a humble lodging in the Old Bailey, and endeavoured for a time to support his seven children by contributing to periodical publications, especially the *Critical Review* and the *British Lady's Magazine*. At length, however, he found means to set up once more as bookseller in a small shop in Fleet Street. Here he was again unfortunate in having his premises twice broken into and plundered. In 1815 he became publisher of the *Traveller* newspaper. In 1816 he commenced a weekly paper called *The Reformists' Register*. The next year he brought himself into great notoriety by a series of political satires, which had immense success, the effect partly of the woodcut embellishments from the designs of Mr. George Cruikshank. Those of the series that turned out the most productive for the author were three composed in the manner of parodies upon various parts of the Book of Common Prayer. For the printing and publishing of these parodies Hone was brought to trial on three several indictments in the Court of King's Bench, on the 18th, 19th, and 20th December, 1817. He defended himself on all the three trials, which were before special juries, and, notwithstanding the best exertions of the bench to procure a conviction, was acquitted on each indictment. His acquittal was followed by the subscription of a considerable sum of money for his use, which enabled him to remove from Fleet Street to a large house on Ludgate Hill, where he continued a few years, but was unsuccessful. In 1823 he published the results of researches to which he had been originally directed with a view to his defence, in an octavo volume entitled 'Ancient Mysteries Described, especially the English Miracle Plays founded on Apocryphal New Testament Story extant among the unpublished MSS. in the British Museum.' In 1826 Hone began the publication, in weekly numbers, of his 'Every Day Book.' The sale was large, but his family had now increased to

ten children, and he again got into difficulties; the end of which was that he was arrested by a creditor and thrown into the King's Bench prison. Here he remained for about three years, during which time he finished his 'Every Day Book,' in two volumes, and began and finished his 'Table Book,' in one volume, and also his 'Year Book,' in one volume.

During the latter years of Mr. Hone's life he was employed as sub-editor of the *Patriot* newspaper. He died at Tottenham on the 6th of November, 1842.

HONES are stones used for the purpose of whetting or sharpening knives, scythes, and edge-tools. They are of many sorts, the finest being varieties of slate, called oil-stones. The best are brought from Turkey. Those used for sharpening scythes and other large blades are made of coarse sandstone.

In the year 1865 the number of hones imported into the United Kingdom was 8057, of the value of 276*l.*; and in the same year 600 hones, value 12*l.*, were exported.

HONEY is a fluid or semi-fluid substance, the materials of which are collected by different kinds of bees, in Europe chiefly by the *Apis mellifica*, or hive-bee [BEE], and solely by the neuter or working bees, from the nectariferous glands in the cup or chalice of flowers. It cannot be said to be a purely vegetable production, for, after being collected by the proboscis of the insect, it is transmitted to that distension of the œsophagus termed the crop, sucking-stomach, or honey-bag, where it is elaborated, and again disgorged, to be deposited in the cell of the honey-comb. It undergoes less change when the bees are very young, remaining nearly white, and is then denominated virgin honey. At all times it retains qualities derived from the kind of plant whence it has been procured, as is manifest not only by the peculiar odour of the honey, but by the effects which follow the use of honey obtained from certain plants, chiefly of the sub-tribe *Rhodoraceæ*, such as the azalea, rhododendron, kalmia, &c., which yield a honey frequently poisonous, while that from the genus *Erica* (termed Heather-honey), and most *labiate* plants, is wholesome.

Honey is sweet, faintly aromatic, granular, soluble in water, and capable of undergoing the vinous fermentation, and so yielding an intoxicating drink called hydromel, metheglin, or mead. Honey is certainly nutritive, but it cannot be employed to any great extent, since if taken in considerable quantity it excites the action of the bowels, and is gently laxative. Its effects in this way will be greater in proportion to its age and acidity, and less, or scarcely appreciable, when largely diluted with water. In the latter state it is rather demulcent, emollient, and refrigerant, and hence forms a good drink in fever and other inflammatory complaints, but it should not be taken if there be much gastric or intestinal irritation. It is used likewise in catarrhs, and when drunk warm is considered to be expectorant. Along with vinegar it forms a good gargle in slight cases of sore throat, and combined with borax a most efficacious application in aphthæ of the mouth and throat.

In the year 1865 the quantity received into the United Kingdom amounted to 4519 cwt., of the value of 7475*l.*; and in the same year 758 cwt., value 1254*l.*, were exported. The best description

comes from France and Greece, the latter being generally deemed a table delicacy. The coarser kinds are sometimes used to give a spurious sweetness to tobacco. Honey is often adulterated—generally with flour—but the chief impurities rise to the surface if it is gently heated, and may be easily skimmed off.

HONEY-COMB. [BEE.]

HONEY-COMBS in guns are marks or indentations in the metals, caused by the frequent explosion of gunpowder. They are so termed from their resemblance to the cells which bees form in the comb. In time, they spread and eat into the barrel to such an extent as to render it unsafe. As it is the action of firing which causes them, no remedy can be applied.

HONEY-DEW, a juice which exudes from trees and herbaceous plants in warm dry weather, and concretes on the bark of the plant. It occasionally flows from the leaves. It is a sweet viscid fluid, and often produced by the aphid [APHIS] and other insects which feed on the juices of plants. Sometimes, however, it flows from any wound in the bark, such as cracks made by heat, &c. When allowed to dry on the tree, fungi, mould, and other extraneous substances form in it, and soon injure the health of the tree. Manna is dried honey-dew. [MANNA.]

HONEY-EATERS. [MELIPHAGIDÆ.]

HONEY-SUCKLE. [LONICERA.]

HONFLEUR. [CALVADOS.]

HONG-KONG, or HIANG-KIANG (*Fragrant Streams*), is one of the group of rocky islands situate at the mouth of the Canton River, about 37 miles south of Macao, and 100 from Canton, in lat. 22° 12' N., long. 114° 3' E. It is separated from the mainland of China by a narrow strait, which varies from less than a mile to four or five miles in width. The island is about eight miles long, with a breadth of from two to six miles. Its area is 29 square miles.

Hong-Kong was taken possession of by the British during the first war with China, and was formally ceded to them by the treaty of Nankin, August 30, 1842. On the 26th June, 1843, it was regularly constituted a British colony. It is what is called a crown colony—that is, it has no legislative assembly, but is governed by orders from the Colonial Office in London. There is a legislative and executive council to aid the governor with their assistance and advice. The offices of the government are at Victoria, the chief town. There is a chief-justice and attorney-general, with other law officers, and the usual departments of a colonial administration.

At the time when the British first occupied Hong-Kong, the number of Chinese inhabitants was supposed to amount to only about 5000, consisting chiefly of fishermen and smugglers. Since it became a British colony there has been a great increase of Chinese. They make themselves generally useful as domestic servants, labourers, tailors, shoemakers, builders, carpenters, &c., and become tenants of the little shops in the Chinese bazaars. There is a small body of Chinese police.

The census of 1863 showed the population of the colony to be 124,850—1644 Europeans, 1336 Portuguese, Indians, and mixed blood, and 100 aliens or temporary residents, leaving 121,770 Chinese. The

number of boats plying in the harbour and bays showed a total of 4019, with a population on board of 16,233 men, 6529 women, 4901 male children, and 2884 female children, or a total of boat population amounting to 30,547.

The northern side of the island is traversed by a ridge of mountains, which vary in height from 500 to upwards of 1800 feet, three of the summits being 1575, 1711, and 1827 feet high respectively. The south side is less mountainous. The cultivable land is small, but the supply of water is abundant. The climate is subject to great fluctuations, and is still unhealthy for Europeans, although cultivation and drainage have rendered it much more salubrious than formerly. It is generally exceedingly hot and damp in summer, and cold and dry in winter—the great change producing dangerous diseases, especially of the kidneys.

There is a good anchorage at Hong-Kong Roads and Victoria Harbour, both near the town of Victoria. The commerce of Hong-Kong is inferior to that of the principal treaty ports of China; but as a British colony on Chinese soil, it is most important in its political and defensive position, and is the headquarters of the military, naval, and mercantile establishments. There are several daily and other newspapers printed here in the English language, and one three times a week in Chinese. Regular steam communication is kept up with England, India, Manilla, Canton, Macao, Shanghai, and all the northern ports. The shortest sea voyage to London is 12,900 miles; the quickest time by sailing vessel, 102 days. In 1864 the total number of vessels which arrived at the port was 2264 (1,013,748 tons), being an increase of 442 ships and 118,824 tons, as compared with the previous year. Of the vessels, 1013 were British and 1221 foreign; and the proportion of British to foreign ships in the increase was—British, 227; foreign, 215. Hong-Kong being a free port, no return of imports and exports can be given; but from the official tables compiled in England, it appears that in 1865 the exports to Hong-Kong from the United Kingdom were valued at 1,587,647*l.*; consisting chiefly of cotton goods and cotton yarn, 899,958*l.*, and wools, 224,310*l.* The imports into the United Kingdom from Hong-Kong in the same year were valued at 773,068*l.*; the chief articles being raw cotton, 532,059*l.*; tea, 79,094*l.*; and silk, 17,245*l.*

Since the British took possession of it, the government have formed many miles of good roads round the island; excellent docks, gas and water works, have been established at Victoria, the capital, and numerous Chinese and European schools set up throughout the colony.

Hong-Kong is the seat of a bishopric, and, in addition to the Established Church, has places of worship for Roman Catholics and various dissenting denominations. In 1864 (the latest year for which returns are issued) the revenue amounted to 637,846 dollars, and the expenditure to 763,307 dollars.

Victoria, the chief town of the colony, stretches for four miles along the northern coast of the island, and, according to the latest return, had a population of about 10,000, though it is probable the number has by this time considerably increased. The command of cheap (Chinese) labour to any extent has been one great cause of the rapid progress of this

place, the building of which was not commenced till August, 1841. It is now laid out in magnificent streets and terraces on the steep declivity of Victoria Peak, with numerous fine public buildings and store-houses; picturesque private dwellings, surrounded by gardens; and houses built of stone in the European style. A good road connects the capital with the town of Stanley.

On the mainland, opposite the northern shore, is the Kow-lung peninsula, a strip of coast territory and portion of the township of the same name, which was ceded to Great Britain by the convention of Peking in 1861.

(*Consular Reports*; Milner's *Gallery of Geography*; Johnston's *Dictionary of Geography*.)

HONITON. [DEVONSHIRE.]

HONOLULU, the chief town of the Sandwich Islands, Pacific Ocean, is a seaport in the island of Oahu, in lat. 21° 30' N, long. 158° W. In 1863 the population was estimated at 14,310. It is an *entrepôt* for European and Indian goods; and sugar, coffee, hides, tallow, rice, wool, salt, whale-oil, pumpkins, melons, oranges, limes, &c., are exported. In 1864 the number of whalers that called at the port was 140. An English journal, the *Polynesian*, is published here; and the town has its theatre, hospital, music-halls, billiard-rooms, taverns, and a fashionable drive. Foreign merchants represent as consuls nearly all the states of Europe.

HONORARIUM, a recompense for the services of a counsel or physician, so called because the fees were presumed to be given beforehand, and as a present or gift. Until recently, neither counsel nor physician could recover their fees by legal process; but as the law now stands, the latter can get a judgment for their fees by action. The old law remains in force with regard to counsel, and in the remarkable case *Kennedy v. Broun*, 1863, it was decided that a counsel cannot validly make a special agreement for a fixed sum, nor recover against his client in default of payment.

HONORIUS, son of Theodosius the Great, and younger brother of Arcadius, was born at Constantinople in 384. After the death of his father in 395, Honorius had for his share the Empire of the West, under the guardianship of Stilichon. Honorius fixed his residence at Milan. For several years after, Stilichon was the real sovereign of the West; and he also endeavoured to extend his sway over the territories of Arcadius in the East, under pretence of defending them against the Goths. He gave his daughter Maria in marriage to Honorius, and recovered the province of Africa, which had revolted. In the year 402 Alaric came a second time into Italy, when Stilichon hastily collected an army, with which he met Alaric at Pollentia, on the banks of the Tanaro, and obliged him to recross the Noric Alps. After this victory Honorius repaired to Rome with Stilichon, where they were both received with great applause. In the year 404 Honorius left Rome for Ravenna, which he made his residence, in consequence of which the province in which Ravenna is situated assumed the name of Romania, Romaniola, and afterwards Romagna, which it still retains. In the following year Radagaisus again invaded Italy with a large force of barbarians, but he was defeated and put to death by Stilichon. In the next year

the Vandals, the Alani, the Alemanni, and other barbarians, crossed the Rhine, and invaded Gaul. Constantine in Britain usurped the imperial power, and, having passed over into Gaul, established his dominion there, and was acknowledged by Honorius as his colleague. Stilichon now began to be suspected of having an understanding with the barbarians, and he was put to death by order of Honorius, in 408. His death was fatal to the empire. Alaric again invaded Italy, took Rome, and proclaimed the prefect Attalus emperor. [ALARIC.] The indecision and bad faith of Honorius brought Alaric again before Rome, which was plundered, in 410. After Alaric's death his son Ataulphus married Placidia, sister of Honorius, and took possession of Spain. Honorius died at Ravenna, in August, 423, leaving no issue.

HONORIUS I. II. III. IV. [POPE.]

HONOUR, COURT OF, in military matters, a term applied to a board of inquiry appointed to ascertain the degree of guilt attached to misconduct, and also to decide whether the individuals charged may or may not have been guilty of ignominious behaviour.

HONOURABLE, MOST HONOURABLE, and RIGHT HONOURABLE, are titles given in the United Kingdom to peers, their families, and persons holding certain public situations. A marquis or marchioness is styled Most Honourable; peers, peeresses, younger sons of dukes and of marquises, and their wives, and all the daughters of dukes, marquises, and earls, are styled Right Honourable. The younger sons of earls, and all the children of viscounts and barons, have the title Honourable. The prefix Right Honourable is also bestowed on Privy Councillors, the lord mayors of London, York, and Dublin, the lord advocate of Scotland, and the lord provost of Edinburgh; maids of honour, lords of session, the supreme judges of England and Ireland, are entitled to be designated Honourable. Members of the House of Commons are, during debate, addressed as Honourable, but do not prefix the title to their names in ordinary usage. In America, nearly all persons taking prominent parts in public affairs are styled Honourable.

HONOURS OF WAR, a military term applied to the conditions under which a fort or city is evacuated. In some cases the retreating forces are allowed to depart with all their colours, baggage, artillery, &c.; in others they have to retire to a distance, pile their arms, and surrender as prisoners of war. *Military Honours* are salutations paid to crowned heads or officers of rank, by the discharge of artillery, dropping colours, and other modes.

HONTHORST, GERHARD, called by the Italians Gherardo dalle Notti, from his effects of light by night, was born at Utrecht in 1592. He was the pupil of A. Bloemart, studied some time in Rome, and was engaged for six months by Charles I. in England. There are several portraits by him at Hampton Court, for which he received 3000 florins, a service of plate complete for twelve persons, and a beautiful horse. Honthorst was the favourite painter of the queen of Bohemia, and he was the court-painter to the prince of Orange. He died at the Hague in 1662.

HOOD, ROBIN, is supposed to have lived in the reign of Richard I. He was the most distinguished

in his time of those numerous outlaws who, under the tyrannical government of the early Norman kings, lived in bands in all the great forests, and combined a sort of championship of the cause of the old national independence with the practice of deer-shooting and robbery. The chief residence of Robin Hood and his followers was the forest of Shirewood, or Sherwood, in Nottinghamshire; but he is said to have also frequented Barnsdale in Yorkshire, and Plumpton Park in Cumberland. 'The personal courage of this celebrated outlaw,' Bishop Percy observes, 'his skill in archery, his humanity, and especially his levelling principle of taking from the rich and giving to the poor, have in all ages rendered him the favourite of the common people.' His exploits appear to have been a common subject of popular song. Of Robin Hood's followers the most celebrated were Little John, his chaplain called Friar Tuck, and his paramour named Marian. Amidst a variety of conflicting statements it is difficult to arrive at any distinct facts relating to this celebrated personage. He seems to have died in 1247.

HOOD, SAMUEL, VISCOUNT, was born December 12, 1724, at Butleigh in Somersetshire, of which parish his father was the incumbent. He was brought up to the navy, and was appointed in 1757 to command the *Antelope*, 50 guns, in which he took a French 50-gun ship. In 1759, in the *Vestal*, 32 guns, he was again successful in capturing the *Bel-lona*, a French frigate of equal force. He served in the Mediterranean, under Sir Charles Saunders, till the end of the war in 1763, and was appointed to command on the Boston station in 1768. In 1778 his services were rewarded with a baronetcy. In 1780 he was promoted to the rank of rear-admiral, and sailed with a squadron to the West Indies to join Sir George Rodney. By Rodney's departure to England, in 1781, Hood succeeded to the command of the fleet. The events of the war called him almost immediately to America. In January, 1782, the French invaded the island of St. Christopher. Hood hastened to relieve it; but, notwithstanding a dexterous manœuvre, he was unable to prevent the surrender of the island. His conduct in the whole of this affair has been warmly applauded by naval critics. After the action of April 12, 1782, in which the French fleet in the West Indies, under the Comte de Grasse, was defeated by the British fleet under Admiral Rodney, Hood, who commanded a part of the fleet and greatly distinguished himself, was created an Irish peer by the title of Baron Hood of Catherington, and Rodney returned finally to England, leaving Lord Hood again in the chief command, which he retained till the peace of 1783. In the memorable Westminster election of 1784 Lord Hood opposed Fox, and was returned at the head of the poll. He lost his seat on being made a lord of the Admiralty in 1788, but was re-elected in 1790. In 1793 he was appointed to command the Mediterranean fleet, and an arduous responsibility devolved on him in consequence of the surrender of Toulon to the British and Spanish fleet by the French royalists. Early in 1794 Lord Hood applied himself to the expulsion of the French from Corsica, which was accomplished chiefly by the astonishing exertions of the British sailors on shore, especially in the capture of Bastia, for which Lord Hood received the thanks of both

Houses of Parliament. His health being much impaired, he returned to England at the close of the year. In 1796 he was appointed governor of Greenwich Hospital, and raised to the English peerage by the title of Viscount Hood of Whitley. He afterwards received the Grand Cross of the Bath. He died at Bath, in his ninety-second year, June 27, 1816.

HOOD, ALEXANDER, VISCOUNT BRIDPORT, younger brother of the above, was also brought up to the navy, and found many opportunities of signalizing his skill, activity, and bravery. He was made rear-admiral in 1780, and in 1782 sailed as second in command of the fleet sent under Lord Howe to relieve Gibraltar. He held the same rank in the Channel fleet, under the same commander, in 1794, and bore a distinguished part in the great victory on the 1st of June. In 1795 he engaged a French fleet off L'Orient, and took three ships of the line; and in the following year was appointed to the command of the Channel fleet, which he held till April, 1800. He was successively raised to the Irish and English peerage by the titles of Baron and Viscount Bridport, the last creation June 10, 1801. Lord Bridport died at Bath, May 3, 1814. The title is now extinct.

HOOD, THOMAS, was born in 1798, in the Poultry, London, where his father was a bookseller of the firm of Vernor and Hood. In 1811 Hood's father died, and his mother sent him to a day-school. From this school he was removed to the counting-house of Messrs. Bell and Co., Russia merchants, Warford Court, City, but his health soon began to fail, and he took up his abode at Dundee. After a residence of two years, he returned to London, and engaged himself to his uncle Mr. Robert Sands, an engraver, in order to learn his art, and was afterwards with Le Keux for the same purpose.

Hood had published some trifles in the *Dundee Advertiser* and *Dundee Magazine*. In 1821 he succeeded Mr. John Scott as editor of the *London Magazine*. His first publication in a separate form was 'Odes and Addresses to Great People,' in which he was assisted by his brother-in-law, J. H. Reynolds, and which was brought out anonymously. 'Whims and Oddities,' published in 1826, in small 8vo., consisted chiefly of his contributions to the *London Magazine*, with some additions. His next work was in prose, 'National Tales,' which was followed by 'The Plea of the Midsummer Fairies, Hero and Leander, Lycus the Centaur, and other Poems.'

He commenced the 'Comic Annual' in 1829, and continued it nine years. In the same year his comic poem of 'The Epping Hunt' came out. He was for one year editor of *The Gem*, and wrote for it his poem called 'Eugene Aram's Dream.'

In the spring of 1834 Hood became the occupier of a house called Lake House, in Essex. While residing here he wrote his novel of 'Tylney Hall.' Pecuniary difficulties compelled him to leave his pleasant residence in 1835. The 'Comic Annual' having terminated in 1837, Hood commenced the publication of 'Hood's Own,' in a series of monthly numbers. He afterwards went to the Continent for the benefit of his health, and in Belgium he published his 'Up the Rhine.' On his return he became editor of the *New Monthly Magazine*; after his retirement in 1843, he collected his contributions to that work,

and, with additions of prose and poetry, published them under the title of 'Whimsicalities.'

In 1844 Hood started his last periodical, *Hood's Magazine*, and continued to supply the best of its contributions till within about a month before his death. Those who have read the work, and have a taste for wit, humour, and character, will not readily forget his 'Schoolmistress Abroad,' and his novel of 'Our Family,' which was interrupted by his last illness and death: the last chapters were in fact written by him when he was propped up by pillows in bed. Hood was an occasional contributor to *Punch*, and it was in that periodical his immortal 'Song of the Shirt' first appeared. He had the consolation, a short time before his death, of having a government pension of 100*l.* a year offered to him by Sir Robert Peel, which was transferred at his own request to his wife. He died May 3, 1845, and was buried in Kensal Green Cemetery. An appropriate monument, raised by public subscription, has since been erected there to his memory.

HOOF. The horny substance which covers or terminates the feet of certain animals, as oxen, horses, sheep, goats, deer, &c. The value of the hoofs imported into the United Kingdom in 1865 was 1480*l.*

HOOF, PETER CORNELIUS, one of the most eminent poets and prose writers of Holland, was born on the 16th of March, 1581, at Amsterdam, where his father was an eminent burgomaster. He wrote 'Granida,' and several other tragedies, and may be considered in some degree as the founder of the Dutch stage. His tragedies are composed on the Greek model, and have choruses. In his lesser poetical productions he displays more originality, and many of them are distinguished by playfulness and elegance. He also formed a correct and harmonious style of prose, of which his 'History of the Netherlands' is esteemed a model. He died May 21, 1647.

HOOG, PETER DE, was born about 1643, but the place of his birth is uncertain, as well as the master under whom he studied. His pictures, of which there are some capital specimens in England, sell at high prices.

HOOGVEEN, HENRY, was born at Leyden in January, 1712. His parents were in humble circumstances. He filled successively the office of rector at the gymnasiums of Kuilenburg, Breda, Dort, and Delft, at the last of which places he died in 1791.

The principal work of Hoogveen is a treatise on the Greek Particles (2 vols. 4to., Leyden, 1769), of which an abridgment was made by Schütz (Leipzig, 1806); one of the most useful of his works, entitled 'Dictionarium Analogieum Lingue Græcæ,' was published after his death at Cambridge, in 1800.

HOOGLY, a river of India, in the presidency of Bengal, formed by two branches of the Ganges—the Bhagruttee and the Jellinghee—which join each other in lat. 23° 25' N., long. 88° 22' E., 160 miles from the sea. During the south-west monsoon, when a great current is driven into the river from the Bay of Bengal, it produces a phenomenon called 'the Bore,' when the tide rises on the sands near the banks in waves 12 or 15 feet high, and rushes along at the rate of 20 miles an hour, driving before it the shipping in its course. The Hooghly is one mile wide at Calcutta, and ships drawing 17

feet of water can go up thus far, but the river is said to be gradually silting up. Here the tides are often violent and rapid, running at the rate of seven miles per hour. It is 15 miles wide at the mouth, and much encumbered by shoals, through which it requires great care to steer large ships. (Johnston's *Dictionary of Geography*.)

HOOGLY, a district in the presidency of Bengal, British India, comprising an area of 2089 square miles, and a population of 1,520,840, of whom two-thirds are Brahmins, the remainder Mussulmans and Christians. This district is low and level in the east, but hilly in the west and north-west, where it stretches towards the high lands of Burdwan. The principal rivers are the Hooghly, the Damoodah, the Dalkissore, and several other lesser streams. Hooghly was ceded to the English in 1765. The chief crops now are rice, sugar-cane, mustard, ginger, potatoes, indigo, tobacco, cotton, hemp, oil-seeds, vegetables of various kinds, and the mulberry tree. There are also manufactures of rope, sacking, and coarse canvas. Silk, indigo, and sugar are the principal articles exported. The wild animals are elephants, buffaloes, tigers, and wolves. Winter continues from the beginning of November to the end of January, and the nights are so cold that ice is formed. During the dry hot season, from the beginning of March to the end of June, the thermometer ranges from 75° to 110° Fahrenheit. The rainy season commences about the end of June, and lasts till the beginning of October, during which time fever and agues are very prevalent. The chief towns are Hooghly, Serampore, Ghotal, Ompah, and Shahbazar.

HOOGLY or HOOGLY, a town of British India, capital of the district of the same name, in the presidency of Bengal, on the right or western bank of the Hooghly River, 27 miles north of Calcutta, on the Calcutta and Burdwan Railway. The population, according to the latest return, is 12,000. The town was founded by the Portuguese in 1537; in 1676 the Dutch and English established factories here; and in 1757 it was finally taken by Clive, since which it has remained in the possession of the British. It has a civil establishment, consisting of judges, collectors, magistrates, and surgeons, and a government college, in which English and Oriental languages are taught, and in connection with which are several branch schools.

HOOK, THEODORE EDWARD, was born September 22, 1788, in Charlotte Street, Bedford Square, London. He was the son of James Hook, a musical composer of some celebrity, by his first wife (Miss Madden). There was only one other child by that marriage, Dr. James Hook, dean of Worcester.

Theodore Hook was a handsome boy and remarkably clever. He had a fine ear, was an expert performer on the pianoforte, and had a sweet and powerful voice. His father was employed at Vauxhall and the theatres, and Theodore wrote songs for him, and sometimes composed the airs. In 1805 he wrote an operatic farce, 'The Soldier's Return,' which was very successful. He afterwards wrote several other successful operatic pieces and farces. In 1809 he made his first essay as a novelist by the publication of 'The Man of Sorrow.' It was a very flimsy work, and had no success.

Hook was even at this period distinguished for his

conversational powers, but his talent as an *improvisatore* is described as extraordinary. He was invited to perform before the prince regent, who was so much delighted, that in 1812 he got him appointed accountant-general and treasurer to the colony of the Mauritius, with a salary and allowances amounting to nearly 2000*l.* a year. He reached his destination October 9, 1813. In 1817 a large deficiency in the assets of the office was discovered; an investigation took place, and Hook was arrested on the 9th of March, 1818; all his property was seized, and he was sent back to England in custody. The result of an examination of the matter by the law-officers of the crown was a claim upon him for 12,000*l.*

The *John Bull* newspaper was established soon after Hook's return, and he became the editor. Hook, in its prosperous state, received full 2000*l.* a year from it; and, though its circulation gradually diminished, he derived a considerable profit from it up to the time of his death. In August, 1823, Hook was arrested under a writ of Exchequer; his property was sold, and realized about 40*l.*; and he was taken to a spunging-house, where he remained till April, 1824, whence he was transferred to the King's Bench, where he remained till May, 1825, when he was released from custody, but with an intimation that the crown abandoned nothing of its claim for the debt.

Hook published his first series of 'Sayings and Doings' in Feb. 1824, while confined in the spunging-house, and his diary records the profit to have been 2000*l.*; and he realized sums almost as large by the novels and other works which he published in rapid succession afterwards. The following is a list of the whole of them:—'Sayings and Doings,' First Series, 3 vols., 1824; Second Series, 3 vols., 1825; Third Series, 3 vols., 1828; 'Maxwell,' 3 vols., 1830; 'Life of Sir David Baird,' 2 vols. 8vo., 1832; 'Parson's Daughter,' 3 vols., 1833; 'Love and Pride,' 3 vols., 1833; 'Gilbert Gurney,' 3 vols., 1835; 'Jack Brag,' 3 vols., 1837; 'Births, Deaths, and Marriages,' 3 vols., 1839; 'Gurney Married,' 3 vols., 1839; 'Precepts and Practice,' 3 vols., 1840; 'Fathers and Sons,' 3 vols., 1840; 'Peregrine Bunce,' 3 vols., 1841, some months after his death. In 1836 he became editor of the *New Monthly Magazine*. He wrote Kelly's 'Reminiscences,' from Kelly's notes, in 1836, without any remuneration.

While residing at Putney he gradually mixed more and more freely in society, and in 1827 took a house in Cleveland Row, St. James'; he became a member of divers first-rate clubs, received invitations from persons of the highest distinction, and ran himself rapidly and deeply into debt, notwithstanding the large sums which he obtained by his literary labours. By his extravagance, which he supplied at a ruinous expense of labour of mind and body, his constitution was completely broken up. He died August 24, 1841, in the fifty-third year of his age.

HOOKAH, an Indian tobacco-pipe, the stem or tube of which is made of cocoa-nut, while some ornamental tubing lengthens it out into several coils. The mouth-piece is usually of amber; the bowl of shell, silver, or earthenware; and the smoke passes through a glass water-vase. These hookahs are in almost universal use among the upper classes of the

Arabs, Turks, Indians, Egyptians, and other Oriental nations; and on all occasions of friendly visits they are considered as the calumet of peace.

HOOKE, NATHANIEL, born in 1690, died in 1764. He was a Roman Catholic, enjoyed the friendship of Pope, and was intimate with most of his eminent literary contemporaries. He is said to have lost his fortune in the South Sea scheme. The work by which Hooke is principally known is entitled 'The Roman History, from the Building of Rome to the Ruin of the Commonwealth,' which was originally published in 4 vols. 4to., 1733-1771. Hooke also published a work on the Roman senate in answer to Dr. Middleton's and Dr. Chapman's treatises on the same subject, 1758, and translated from the French the 'Life of Fenelon,' 1723, and Ramsay's 'Travels of Cyrus,' 1739.

HOOKE, ROBERT, was born July 18, 1635, at Freshwater, in the Isle of Wight, of which parish his father was minister. After studying successively at Westminster and Oxford, he was engaged to assist Dr. Wallis in his chemical experiments, and he subsequently served Mr. Robert Boyle in a similar capacity. In 1662 he was appointed curator of experiments to the Royal Society; and when that body was incorporated by charter the following year, Mr. Hooke was one of those Fellows who were first nominated by the council. In 1664 he succeeded Dr. Dacres as professor of geometry in Gresham College, and two years afterwards received the appointment of city surveyor. In 1677 he succeeded Oldenburg as secretary to the Royal Society. In 1691 he was created Doctor of Physic, by a warrant from Archbishop Tillotson. He died at Gresham College in 1702, in his sixty-eighth year. A list of the works left by Dr. Hooke is given in Ward's 'Lives of the Gresham Professors.'

HOOKE, RICHARD, was born at Heavitree, near Exeter, about 1553 or 1554. He was introduced by his uncle, the chamberlain of Exeter, to the notice of Bishop Jewel, who procured him, in 1567, a clerkship in Corpus Christi College, Oxford. In December, 1573, he became a scholar of that college, and a fellow and master of arts in 1577. In 1579 he was appointed lecturer of Hebrew in the university, and in October of the same year he was expelled his college, with Dr. John Reynolds and three other Fellows, but restored the same month. In about two years he took orders, and was appointed to preach at Paul's Cross, London. Through the influence of the archbishop of York, he was appointed Master of the Temple in 1585, and was presented to the living of Boscombe, in Wiltshire, in 1591. On July 17 in the same year he was made a prebendary of Salisbury. On July 7, 1595, he was presented to the living of Bishopsbourne in Kent, which he held till his death on November 2, 1600. His great work is his defence of the constitution and discipline of the Church of England, in eight books, under the title of 'The Laws of Ecclesiastical Polity.'

HOOKS and EYES are well known articles used for fastening ladies' and children's dresses. They are made entirely by machinery, from the unreeling of the wire through all the cutting and bending processes until ready for use, and at such a rate, that one machine will manufacture 100 hooks and the same number of eyes in a minute.

HOOKE, JOHN, was born in London in 1727. At the age of seventeen he became a clerk in the East India House. He is chiefly known for his translation of Tasso's 'Jerusalem Delivered,' London, 1763, 2 vols. 8vo. It is a diffuse and feeble version. He published also a translation of Ariosto's 'Orlando Furioso,' 5 vols. 8vo. He translated many of the dramas of Metastasio; and he wrote three or four tragedies, which were unsuccessful. He died in 1803.

HOOPER, JOHN, one of the most venerated martyrs of the Reformation, was born in Somersetshire about 1495, and educated at Oxford. In 1550 he was appointed bishop of Gloucester; but his assumption of the office was long delayed by his scrupulousness as to the use of the episcopal dress. By way of overcoming his reluctance, he was confined to his house, and finally committed to the Fleet Prison. His friends exhorted him to compliance, and at length the matter was compromised. In 1552 he received the bishopric of Worcester in commendam. Wood says, 'When Queen Mary began to reign, in July, 1553, he was persuianted up to London, in the latter end of August, and committed to the Fleet, where, remaining some months, he was at length examined several times, and required to recant his opinions, but standing constant and resolute to them, was condemned to be burnt. He suffered, February 9, 1555, at Gloucester, bearing his torments with great courage.'

HOOPING-COUGH. This disease, to which, on account of the violence of the cough that attends it, the Latin term *Pertussis* has been applied, has also obtained the popular designation Chin or Kink Cough.

It commences with the symptoms of simple catarrh, and is indicated by cough and the expectoration of a clear limpid fluid, by redness of the conjunctive, a watery discharge from the eyes and nostrils, hoarseness, and occasional sneezing. These symptoms are attended by some degree of fever, which in general, however, is very slight; the patient is languid and out of spirits, but is free from pain, or complains only of soreness in the anterior part of the chest. At the end of a period varying from one to two weeks, the fits of coughing become longer and more frequent; each fit is commonly announced by a sensation of tickling in the larynx and trachea, during which the inspirations are irregular and incomplete, especially in children, whose countenances are at this time expressive of fear and anxiety. At the moment the fit comes on they cling with firmness to the persons or objects around them; if asleep at the time of its accession, they suddenly start up and place themselves in a sitting posture. The efforts of coughing are now repeated in such quick succession as to suspend almost completely the act of breathing; during their brief intervals we can with difficulty perceive any inspiratory movements, excepting at times when the cough is momentarily interrupted by a prolonged inspiration attended by a peculiar whooping noise, which has supplied a name for the affection, and which constitutes its characteristic symptom. In consequence of the obstruction to the circulation occasioned by these long-continued efforts of coughing, the face and neck become swelled, and of a deep red or violet colour; the veins on these parts are distended almost to bursting; the eyes are

prominent and bathed in tears; occasionally the patient becomes completely exhausted; the fit of coughing is interrupted for one or more minutes; it then recurs with the same violence, and the patient seems in imminent danger of suffocation, when the paroxysm is terminated by one or two long and whooping inspirations, and by the rejection of a limpid viscid fluid, which hangs in threads from the mouth. This fluid comes from the bronchi and pharynx, and sometimes also from the stomach; it is occasionally mixed with particles of blood. These paroxysms or fits of coughing continue for many minutes, and when they are very severe blood frequently issues from the nose, mouth, ears, or even from the eyelids; they recur at various and often very short intervals, generally, however, more frequently and with greater severity by night than by day, and they are excited by the slightest causes, as by food or exercise, by any agitation or mental emotion. In the intervals of the fits the child appears to have its ordinary health.

After the affection has presented the characters which we have described for a period which varies from two or three weeks to as many months, the paroxysms become shorter and less frequent, and the cough ceases to be characteristic, but still continues to terminate in vomiting and the discharge of sputa, which now resemble those of catarrh. The paroxysms become more and more rare, in some cases recur at regular intervals, and finally cease, but for some time afterwards they are easily renewed by any unusual exposure to cold.

Whooping-cough prevails epidemically, and chiefly attacks children from birth to the period of second dentition, but it occasionally occurs in adult and even in old age. It rarely affects the same individual more than once, although this sometimes happens, and it is one of those diseases that are contagious.

No method of treatment has hitherto been discovered by which the progress of whooping-cough can be arrested. We may mitigate its severity and somewhat diminish its duration, but it will run a certain course, and this course, in spite of all our efforts, will often be long. In the early stage emetics may be given repeatedly, and at a more advanced period great benefit is derived from the employment of narcotic and sedative medicines, of which opium, hydrocyanic acid, and belladonna are the best; but on account of the powerful influence of these drugs on the system, the greatest caution should be observed in their administration to children.

HOOPOES. [UPUPIDÆ.]

HORN. [HOLLAND.]

HOP-FLY (*Aphis humuli*), a species of insect of the family *Aphides*, or plant-lice. The prevalence of this insect at certain seasons in hop-growing districts determines the price of hops. [HOPS.] This has fluctuated in different years between a loss of from 15,000*l.* to 468,000*l.*, according as the fly abounded. 'It is the barometer that indicates the rise and fall of the hop-growers' wealth, as well as of a very important branch of the revenue.' Hand-picking in spring is the only effectual remedy. The hop-plant is also attacked at the roots by the caterpillar of a moth (*Hepialus humuli*), and by a small beetle (*Haltica cinnamomea*), which is very destructive to the tender shoots.

HOPE, THOMAS, was descended from the wealthy family of the Hopes of Amsterdam. He was born in London, in 1770, and gave very early indications of his attachment to architecture. At the age of eighteen or nineteen he went abroad, and travelled for about eight years in various parts of Asia and Africa, as well as on the continent of Europe.

Soon after his return to England he began to apply his studies practically by remodelling and enlarging his mansion in Duchess Street, Portland Place. He thus rendered his house one of the largest private mansions in the metropolis, and fitted up and furnished the interior in a style of classical taste that was then a novelty in this country. His publication on 'Household Furniture,' in 1805, created a revolution in taste.

In 1809 appeared his 'Costume of the Ancients;' and in the same year he contributed to a periodical (by J. Landseer) entitled *Review of Publications of Art*, an essay on the 'Architecture of Theatres.'

With the exception of a minor work entitled 'Modern Costumes,' in 1812, Mr. Hope did not publish anything further till 1819, when appeared his 'Anastasius, or Memoirs of a Modern Greek at the close of the Eighteenth Century.' His last two works, both of them published posthumously, are, 'The Origin and Prospects of Man,' and an 'Historical Essay on Architecture.' Mr. Hope died on the 3rd of February, 1831.

HOPITAL, or HOSPITAL, MICHEL DE L', born in 1505, near Aigueperse in Auvergne, was the son of Jean de l'Hôpital, physician to the Connétable de Bourbon. L'Hôpital remained in the University of Padua six years, during which the Connétable de Bourbon lost his life under the walls of Rome, and Jean de l'Hôpital found himself without a protector in a foreign land. After practising for some time at the bar of the Parliament of Paris, his merit, added to his having married the daughter of the lieutenant-criminel Morin, procured for him a seat on the bench of the counsellors of the Parliament. The duchess of Berri, daughter of Francis I., invited L'Hôpital to her court, and recommended him to the king, Henri II., who appointed him superintendent of the finances. L'Hôpital endeavoured to check prodigality and corruption. He also opposed the persecution of the Protestants. On the death of the chancellor Olivier, in 1560, L'Hôpital succeeded him. He strenuously opposed the cardinal de Lorraine, who wanted to establish the Inquisition in France; and his next thought was that of assembling the States-general, which had not met for eighty years, but the Guises opposed the proposal. L'Hôpital accordingly contented himself with assembling the nobility and high clergy at Fontainebleau. The only useful result of the assembly was the passing of an ordonnance prepared by L'Hôpital, which abolished arbitrary taxes, regulated the feudal authority of the nobles, and corrected many abuses in the judicial system. Soon after, July, 1561, L'Hôpital obtained from the regent Catherine an edict, ordering the release of all prisoners suspected of heresy. By another edict Roman Catholics were forbidden, under pain of death, from forcing an entrance into the houses of Protestants under pretence of dispersing their meetings. After the death of the duke of Guise, 1563, L'Hôpital

prevailed upon Catherine to grant the edict 'of peace,' by which, among other conditions, all prisoners on both sides were released, and the Protestants were allowed the exercise of their religion within the towns which they had occupied during the war. He also prevailed upon Catherine to declare the majority of her son, Charles IX. L'Hôpital's opposition to the bull of the pope, by which the king was authorized to levy 100,000 crowns a year on the revenues to root heresy from the kingdom, caused his downfall; the seals were taken from him, and he retired in 1568 to his country-house at Vignay, where he died March 15, 1573.

HOPITAL, GUILLAUME - FRANCOIS - ANTOINE L', Marquis de Sainte Mesme and Count d'Entremont, commonly known as the Marquis de l'Hôpital, was born at Paris in the year 1661. He entered the army at an early age, and served some years as a captain of cavalry. His name is intimately connected with the early history of the differential and integral calculus. In 1661 no knowledge whatever of the calculus existed in France; and indeed throughout the Continent it appears to have been known only to Leibnitz, and to the brothers John and James Bernoulli. About this time John Bernoulli arrived at Paris, and spent some time at the residence of L'Hôpital for the purpose of giving him instruction in the differential and integral calculus. With such assistance he was not long in becoming one of the first mathematicians of Europe, and he soon after distinguished himself by his solution of the great problem in mechanics relative to the brachystochron, or curve of quickest descent, which Bernoulli had proposed as a challenge to the geometricians of the day, and to which, at the end of ten months, only four solutions had been given, by Newton in England, Leibnitz in Germany, James Bernoulli in Switzerland, and L'Hôpital in France. Still, however, the calculus was regarded as a sort of mystery by most of those mathematicians by whom it was not actually opposed; and, with the exception of the papers of Leibnitz dispersed in the Acts of Leipzig, there existed no work from which any information could be obtained. To remedy this defect he wrote and published his 'Analyse des Infiniment-Petits,' which appeared in 1696, Paris, 4to. 'The appearance of this work,' says M. Boucharlat, 'marked the epoch of a great revolution in science. Mathematicians hastened to initiate themselves into the wonders of the infinitesimal calculus, and doubts concerning its truth were advanced only by those who were blinded by their prejudices in favour of ancient methods.' At his death in 1704, when only forty-three years of age, L'Hôpital left an 'Analytical Treatise on Conic Sections,' which was published in 4to. the following year, and was for a long time considered the best treatise on the subject.

HOPLITES (Gr. *hoplites*, 'armour'), among the ancient Greeks, such of the candidates at the public games as ran races in armour.

HO-PO-SO. A small port in the Island of Hainan, belonging to Chiuu.

HOPPNER, JOHN, R.A., was born in London in 1759. When young, he was one of the choristers in the Chapel Royal. He studied afterwards in the Royal Academy; and before he was thirty years of age he had, owing to the active patronage of the

prince of Wales, painted more royal and noble portraits than usually falls to the lot of distinguished portrait painters during the whole of a long life. Hoppner's style is easy and effective, but gaudy. He died of dropsy in 1810.

HOPS (Botany). [*HUMULUS LUPULUS*.]

HOPS (*Humulus lupulus* of Linnæus) are extensively cultivated for the flowers or seed-vessels, which give flavour and permanence to beer by being boiled with the wort in brewing.

Hops were introduced into England from Flanders about the year 1524. The most extensive plantations are in Kent, Sussex, and Herefordshire, but they are also cultivated in Worcestershire, Wiltshire, Hampshire, Gloucestershire, Surrey, and several other counties. The hops of Kent and Sussex are the finest in the world. The hop is a slender climbing plant, which requires a very rich mellow soil and careful cultivation. The soil of a hop garden must be rich to a considerable depth, or made so artificially.

The young plants are raised in beds, and may be raised from seed; but it is more usual to plant the young shoots which rise from the bottom of the stems of old plants. The varieties most esteemed are the Grape, the White Vine, the Golden Hill and East Kent Golding, and Farnham White Bine. The young plants are placed in groups of three each, about six inches apart, in the midst of prepared masses of soil about two feet asunder. A watering with liquid manure greatly assists their taking root, and they soon begin to show bines. A stick three or four feet long is then stuck in the middle of the three plants, and the bines are tied to this stick with twine or the shreds of Russia mats, till they lay hold and twine round it. During their growth the ground is well hoed and forked up around the roots, and some of the fine mould is thrown around the stems. In favourable seasons a few hops may be picked from these young plants in the autumn, but in general there is nothing the first year. Early in November the ground is carefully dug with the spade, and the earth being turned towards the plants, is left so all the winter.

In the second year, early in spring, the hillocks around the plants are opened and the roots examined. The last year's shoots are cut off within an inch of the main stem, and all the suckers quite close to it. A pole about twelve feet long is then firmly stuck into the ground near the plants; to this the bines are led and tied as they shoot, till they have taken hold of it. The ground being well hoed and the earth raised round the plants, the produce this year will average 4 cwt. per acre if the season is favourable.

In September the flower containing the seed assumes a fine straw colour turning to a brown; it is then in perfection. No time should then be lost in picking them. The hops when picked are dried on a hair cloth in a kiln. They are then laid in heaps on the floor, where they undergo a very slight heating. As soon as this is observed, they are bagged. This is done by pressing them into large bags suspended below a hole in the floor; when sewed close and tight the bag is stored in a dry place till the hops are wanted for sale.

The crop of the third year will average 8 cwt. per acre, but will in some cases reach 15 cwt.

The hop is a dioecious plant, *i.e.*, some of the individuals are male plants and others female, which have respectively flowers of a different construction and of different habitudes; and the pollen of the former is conveyed by the air to the latter. Though the pollen, from its extreme lightness, can be wafted to a considerable distance, and some seeds in each cone may be so fertilized, yet it would be well to rear a number of the male plants among the others, or along the hedges of the hop-gardens, to insure the fertilization of all the seeds.

The poles are an expensive article; those of chestnut are the most durable, and also the dearest. They should be put into a shed during winter; or else be placed on end in the form of a cone, leaning against each other.

The uncertainty attending the culture of the hop is very great; the crop is most exhaustive of the soil, extracting as much nitrogen from an acre of land as nine hundredweight of guano will replace, and the hop-grower has to contend against a greater number of foes than perhaps any other cultivator.

As the young shoots push themselves from the earth in March, they are attacked by the flea (*Alicea cincinna*); and if the bines survive its assaults, they are liable to destruction by the hop-aphis (*A. humuli*). These assailants appear in May, and settling upon the plants, suck the under-side of the leaves, and deposit thereon their young, the aphis louse, which possesses the curious but inconvenient faculty of increasing and multiplying within a few hours of its birth, without waiting till it becomes a perfect insect. If the lice are allowed to remain undisturbed, they soon extract the juices of the bine; its leaves curl up, turn brown, and finally the bine drops from the pole. Nature has provided a check upon the multiplication of the aphides in the shape of the ladybird, which feeds upon the fly, and lays her eggs among the lice. The wireworm is another enemy to the hop-grower. It usually confines its unwelcome attentions to young grounds; but new and old plantations suffer from the depredations of various species of caterpillars, and the destructive visitations of 'honey-dew,' blight, mould, red-rust, and fire-blast.

In 1869 there were 64,500 acres of land devoted to the cultivation of the hop in England alone. Abroad, the cultivation is carried on in Prussian Poland, North Germany, Bavaria, and Belgium, the entire continental crop being about equal to that of England. North America also produces a considerable quantity of hops, but of such a coarse, rank flavour as to find but little favour with European customers.

The hop serves other purposes besides that of flavouring beer. Medicinally it is sometimes used as a narcotic. A brown dye is extracted from the young leaves; the bines have been converted into brown paper, and made into cloth; the prunings are useful as winter provender for horses and cattle; in Belgium, the young shoots are used as a vegetable in the way we use asparagus; and, lastly, spent hops are useful as a manure.

Till 1862 hops used in England were liable to an excise and customs duty, which, on an average, yielded about 200,000*l.* per annum to the revenue. But owing to the uncertainty attending the crop and other causes, in that year both duties were repealed,

and a charge of 3*d.* per barrel on all beer brewed in the United Kingdom was substituted, and has been found to work much more satisfactorily.

In 1868 the imports of hops into Great Britain amounted to 231,720 cwt*s.*, value 689,883*l.*, chiefly from Hamburg, Belgium, France, and the United States. [*HUMULUS LUPULUS.*]

HOR, MOUNT, a hill forming part of Mount Seir or Edom, in Arabia, nearly intermediate between the head of the Gulf of Akayabah and the Red Sea. It is a steep and irregular truncated cone, having three peaks on the north, in the loftiest of which is a grotto, the reputed tomb of Aaron. A small and plain Mohammedan chapel marks the supposed sepulchre, in which the Arabs suspend ragged shawls, ostrich eggs, and beads as votive offerings.

HORAPOLLO, or HORUS APOLLO, the author of a treatise on Egyptian Hieroglyphics. Champollion, and Leemans, in his edition of the work, are disposed to attribute greater importance to it than former critics had been willing to allow. The best edition is by Leemans, Amsterdam, 1884.

HORARY (Astronomy). The horary motion of the sun or a planet is the arc which it describes in one hour, or the angle which that arc subtends at the eye of the spectator.

HORATIUS, FLACCUS QUINTIUS, was born at Venusia, December 8, B.C. 65. His father, who was a *libertinus*, or freedman, acquired some property (1 'Sat.,' vi. 6, 86), with which he purchased a farm near Venusia, on the banks of the Aufidus. In this place Horace appears to have lived till his eleventh or twelfth year, when his father removed with his son to Rome, where he was placed under the care of a celebrated schoolmaster, Orbilius Pupillus, of Beneventum. After studying the ancient Latin poets (2 'Ep.,' i. 70, 71), Horace learned the Greek language (2 'Ep.,' ii. 41, 42). He also enjoyed during the course of his education the advice of his father, who was a sensible man, and is frequently mentioned by his son with the greatest respect. About the age of seventeen he went to Athens to pursue his studies (2 'Ep.,' ii. 43-45), where he was when Brutus was raising troops to oppose Octavianus Cæsar and M. Antonius. He joined Brutus, was promoted to the rank of a military tribune (1 'Sat.,' vi. 48), and was present at the battle of Philippi, B.C. 42. Though the life of Horace was spared, his paternal property at Venusia was confiscated, and he repaired to Rome with the hope of obtaining a living by his literary exertions. Some of his poems attracted the notice of Virgil and Varius, who introduced him to Mæcenas, whose liberality relieved the poet from all pecuniary difficulties.

From his introduction to Mæcenas till the time of his death, Horace appears to have enjoyed exemption from all cares; he was intimate with Virgil, Tibullus, and other distinguished literary men in Rome, and was a great favourite of his patron Mæcenas, and also of Augustus. He resided principally at Rome, or at his country-house in the Sabine valley, which had been given him by Mæcenas. He also had in the latter part of his life another country residence at Tibur (Tivoli). Horace died on the 27th November, B.C. 8, when he had nearly completed his fifty-eighth year.

The works of Horace have been printed by Mr.

Tate, under the title of 'Horatius Restitutus,' in the order in which Bentley supposes that they were written, Cambridge, 1832. The Satires and Epistles, which are familiar moral discourses, and not poetry in the usual acceptation of the word, are the most valuable of his works. The Odes, which are little more than translations or imitations of the Greek poets, are generally written in a very artificial manner. The best are those in which the poet describes the pleasures of a country life, or touches on the beauties of nature, for which he had the most lively perception and the most exquisite relish; nor are his lyrical productions altogether without those touches which excite our warmer sympathies. The qualities in which Horace excels are good sense, judgment, and purity of taste.

The following are the most esteemed editions of Horace:—Lambinus, 1561; Heinsius, 1629; Bentley, 1711; Burman, 1713; Sanadon, 1728; Mitscherlich, 1800; the edition of Baxter, edited by Gesner and Zeune, frequently printed; Döring, 1828–29; Braunschard, 1833; and Orelli, 1837–38 and 1843–44. Horace has been translated into almost all the European languages, both in prose and verse. Some admirable translations have recently appeared from the pen of Mr. Theodore Martin.

HORDEIN, a peculiar vegetable product found in barley. It is a yellowish powder, insoluble in water. It is not found in pearl-barley, and is therefore supposed to be contained in the husk only.

HORDEUM, the genus of plants to which the corn called Barley belongs. As many as fifteen species of *Hordeum* are distinguished by Professor Kunth, in addition to which there are many varieties. The species are found wild in various places in both the Old and New World; as many as eight inhabit America.

H. distichum is the common summer Barley of England, and that which cultivators seem to prefer; its ears are not so large as those of *H. hexastichum*, but the grains are heavier. It is commonly stated to be a native of Tartary.

H. gymnodistichum, Naked Barley, a species but little cultivated now, is of unknown origin.

H. Zeocriton, Battledore Barley, or Sprat Barley, is little cultivated in England because of the shortness of its straw; its native country is unknown.

H. hexastichum. The native country of this species is unknown. It is the Bere, Bigg, or Winter Barley of farmers, and is particularly valuable for ripening quicker than the common two-rowed Barley, but its grains are lighter. To northern nations with short summers it is, however, invaluable.

H. gymno-hexastichum is extremely productive, and in some parts of Europe it is reckoned the most valuable of all. The French call it, on account of its good qualities, *orge cèleste*.

H. Aegiceras, a most curious species, found in the northern parts of India, and probably in Tartary, as its grains have been sent to England under the name of Tartarian Wheat. Its appearance is more that of wheat than of barley, and its naked grains assist the resemblance. It is, however, a genuine species of *Hordeum*. It appears to be a productive plant, but little is as yet known of its quality in this climate.

Of most of the species there are many varieties,

the most striking of which are those called Black Barleys, on account of the dark colour of their husks.

HOREB, MOUNT. [SINAI.]

HOREHOUND (*Marrubium vulgare*) a perennial herbaceous plant, a native of Britain, found growing by roadsides. It is bushy, and about one foot high, its leaves being of a whitish woolly appearance, and possessing a faint odour, which becomes less by drying. It is a tonic stimulant, much used for the cure of coughs, being a very old-fashioned and excellent remedy. It is usually made into a syrup and mixed with sugar; sometimes candied into the form of rock. Other and finer species of horehound are found in various parts of Europe.

HORIZON (*ὁρίζων*, 'bounding'). The physical horizon is the apparent circle by which the spectator's view is bounded when he is upon a level and uninterrupted plain, such as the surface of the sea. It differs from the astronomical horizon in two points: firstly, because the physical horizon dips, as it is called, or is not at the same level as the eye; and secondly, because the astronomical horizon always supposes the spectator to be at the centre of the earth, and not at the surface.

The plane of the horizon at any place is perpendicular to the direction of a plumb-line, or parallel to the surface of any fluid at rest. At sea, when it is necessary to take the altitude of any heavenly body, the physical horizon is, in tolerably fair weather, sufficiently well defined for the purpose, and, with proper allowance for its dip, is used accordingly. But in land observations with a sextant or other instrument requiring a horizon, the surface of a fluid (generally mercury) is used, which is called an artificial horizon, but might more properly be termed an artificial portion of a horizontal plane.

HORMISDAS. [POPE.]

HORN. The structure of such horns as those of the ox, antelope, goat, and sheep may be described as a number of conical sheaths inserted one into another, the innermost of which lies upon the vascular membrane which covers the bony core. The tip, or that portion of the point of the horn which projects beyond the core, is very dense, and the several layers of which it is composed are scarcely distinguishable; while towards the base the layers may be readily distinguished, owing to their successive terminations forming prominent rings. Horn appears to consist of coagulated albumen; and there is a certain chain of connection between the substance of horns, nails, claws, hoofs, the scales of animals of the armadillo and tortoise kind, of lizards, serpents, and fishes, hair, feathers, and even skin.

The principal kinds of horns employed in manufacturing operations are those of oxen, buffalo, two or three species of deer, and sheep and goats. The first process is to remove the bony core or pith, which is accomplished by steeping the horns in water for several weeks, by which operation the membrane which lies between the core and the horny sheath is so destroyed or softened by putrefaction that the cores may be easily extracted. These are applied to many useful purposes. The solid tip of the horn is sawn off with a frame-saw, and is employed for making knife-handles, umbrella-handles, the tops of whips, buttons, and various other articles. The remainder of the horn, which is employed for

purposes for which thin laminae are required, may either be left entire or sawn into two or more lengths, according to the use to which it is to be applied. When divided, the lower part, or that next the root of the horn, is frequently employed for making combs, while the portion which has formed the middle of the horn is used for lanterns and for other articles where a thin plate of horn is required. To prepare the horn for use it is softened in boiling water; and, while hot from this operation, it is held in the flame of a fire until it acquires about the temperature of melting lead, and becomes so soft as to be semi-fluid. The slitting is performed while it is in the semi-fluid state, by a strong pointed knife resembling a pruning-knife; and by the application of two pairs of pinchers, one to each edge of the slit, the cylinder or cone of horn is opened until it is nearly flat. Several such pieces are then exposed to pressure between alternate plates of iron until they are flattened. The thin sheets of horn are then scraped, rubbed, and polished.

The various articles made of horn require manufacturing processes differing in various cases. The making of combs is noticed elsewhere. [COMB-CUTTING.] Umbrella-handles, snuff-boxes, knife-handles, bell-pulls, drawer-knobs, &c., are made by softening the horn to such a degree that it may be pressed into moulds.

Horn is easily dyed of various colours; but in this country it is usually coloured of a rich reddish brown, and spotted to imitate tortoiseshell, by a mixture of pearl-ash, quicklime, and litharge, or red lead, with water and a little pounded dragon's blood.

No part of the refuse of the horn manufacture is without its value. When exposed to a decomposing heat in close vessels, horn produces a large quantity of the gaseous compound which forms the base of prussic acid, on which account hoofs and horn cuttings are in great request among the manufacturers of Prussian blue, and of the beautiful yellow prussiate of potash. The clippings of the comb-maker and of the lantern-maker are also used as manure.

Improvements in the manufacture of horn have recently been made, by which the smallest waste fragments may be united and made into a variety of articles. In France, too, a kind of artificial horn is manufactured from bones treated with muriatic acid, and converted into a horny substance by tanning.

A considerable trade has sprung up in horn—it being estimated that nearly 7000 tons, value 200,000*l.*, are now used annually in England. Sheffield alone requires about 300,000 deer horns yearly to make handles for cutlery.

In 1867 the imports of horns into the United Kingdom were as follows:—Buffalo horns, 1549 tons, value 46,803*l.*; deer horns, 311 tons, value 24,250*l.*; and horns of other sorts, 2080 tons, value 48,150*l.* In the same year 17 tons of deer horns, value 1342*l.*, and 328 tons of horns of other sorts, value 7593*l.*, were exported. The imports are chiefly from the East Indies.

HORN, a musical wind-instrument of very ancient origin, and of various forms.

The *French Horn*, or now, *par excellence*, the *Horn*, is a tube of about ten feet, very narrow at top, widening considerably at the bottom, and bent in rings for the convenience of the performer. It is not

provided with holes, as the flute, &c.; the production of the various sounds depending upon the lips of the player, the more or less pressure of his breath, and the insertion of the hand in the bell, or wide end, of the instrument. Crooks and shifting pieces are provided to adjust the instrument to different keys, or fundamental notes.

Music for the Horn is always written in the key of c, an octave higher than played, and in the treble clef; and the key in which the instrument is to be tuned is indicated by the composer.

The *Bugle Horn* is a tube of three feet ten inches in length, doubled up in a small compass. The *Keyed Bugle*, or a Bugle Horn with keys, is that now in common use, the scale of which comprehends about two octaves, with the semitones. The *Cornopean* and the *Cornet-à-Pistons*, are improved modern forms of this instrument.

The *Russian Horn* is an unjointed brass tube, conical in shape, of various dimensions: the deepest-toned is eight feet long, and nine inches in diameter at the wide end, and the highest is two inches and a half in length, by one at the wide end. The former gives A, an octave below the first space in the base; the latter gives E, the third additional line above the treble. Some of these horns have keys, producing one or two semitones, but generally every note has its separate horn; and a band of Russian Horns counts almost as many individuals as diatonic notes in a scale of between four and five octaves.

Basset Horn. [BASSET HORN.]

The *English Horn* is a deeper-toned oboe, but of rather larger dimensions, somewhat bent, the lower end very open, and is to the latter what the basset horn is to the clarinet; or what the viola is to the violin. The tone of this instrument is extremely pathetic, and by the Italians is thought so much to resemble the human voice, that they sometimes call it the *voce umana*. Its scale is from A below the treble staff, to $\sharp\flat$ above, or two octaves and a semitone.

Of late years, a Frenchman, M. Adolphe Sax, has excited much attention in the musical world by his *Sax-horns*, *Sax-trumpets*, and *Saxophones*. These instruments are a great improvement on those made in the old style, and have had a considerable influence on military music. [SAX-HORN.]

HORN, CAPE. [CAPE HORN.]

HORNBEAM. [CARPINUS.]

HORNBILL, *Hornbill family*, *Buceridae*, a group of birds of considerable size, characterized at once by the enormous and disproportionate development of their beak, and of certain cellular casques or processes surmounting the upper mandible. The generic details may be summed up as follows:—

Genus *Buceros*.—Bill long, very large, and compressed, more or less curved or falcated; base smooth, elevated, or rather surmounted by a casque or helmet-like protuberance; edges of the mandibles smooth or notched; point smooth; interior of the bill, especially the upper mandible and casque, very cellular; nostrils basal, on the surface of the beak, in a furrow, small, somewhat round, open, pierced in the corneous substance of the bill, covered at the base by a membrane. Feet short, strong, muscular; sole of the foot large. Wings moderate; the first three quills graduated; the fourth or fifth the longest.

Geographical Distribution.—Africa, India, and the island of New Guinea.

Its nearest approach, so far as structure goes, is to the Toucan; the toucan, however, in the want of a gall-bladder, agrees with the parrots; the presence of that organ in the hornbill places the bird in more relation with the crows. The disposition of the intestine in long and narrow loops also agrees with the raven. The tongue, so remarkably varied in form and use among the Scansores, resembles in the hornbill that of the carnivorous birds.

For the opinion of various naturalists as to the place these birds hold in the class *Aves*, the writings of Brisson, Linnæus, Latham, Lacépède, Duméril, Illiger, Cuvier, Vieillot, Temminck, Vigors, De Blainville, Lesson, Swainson, and others, may be consulted.

Habits, &c.—Bontius, in his description of the *Corvus indicus* (*Buceros hydrocorax*, Linnæus), says, 'It walks like the crow of our countries, but differs much in disposition from our crows, inasmuch as it feeds not on carcasses, but most especially on nutmegs, and that greedily, doing a great deal of damage to them. Their flesh also is delicate, and when roasted has an aromatic flavour from their food.' Of the *Corvus rostrocornuto* (*Buceros rhinoceros* of Linnæus), he says that it lives on the carcasses and intestines of animals, and that it waits upon the

B. rhinoceros.

hunters who kill wild cattle, boars, and stags, to gorge itself with the entrails of those animals. Cuvier considers the hornbills as omnivorous; and states that they eat tender fruits, mice, small birds, and reptiles, and do not even disdain carrion. The progressive motion of the birds of this genus, although their feet are formed for walking, is always by jumping or hopping. In a state of nature these birds live on wild fruits. In confinement they feed freely on plantains and on boiled rice. At night they perch with great security, though the largeness of the foot seems better suited to rest on the ground. M. Lesson sums up the habits of the hornbills thus:—Those of Africa live on carrion; those of the East Indies seek for fruits, especially nutmegs, and their flesh acquires from them a delicious flavour. Their flight is performed by repeated strokes of the wings, and the air which they displace, joined to the clattering of their

mandibles, occasions a great and very disquieting noise in the forests, when the cause is unknown.

The most familiar examples are *Buceros rhinoceros*, from India and the Indian Islands, and *Buceros cavatus*, from India, the Himalaya range, Java, and most islands of the Indian archipelago. This species, with others, is to be seen in most public museums.

B. cavatus.

HORNBLLENDE. [AUGITE.]

HORNBLLENDE SCHIST is a mineral commonly associated with gneiss, less frequently with mica schist, and seldom forms alone any considerable mountain mass. It follows the contortions of gneiss, and is traversed like it by granitic veins.

HORNCastle. [LINCOLNSHIRE.]

HORNE TOOKE. [TOOKE.]

HORNET. [VESPIDÆ.]

HORNGELD, a tax paid in the feudal ages for horned beasts feeding in the forest; and none could be free without a privilege granted by the king, according to the charter of Henry III.

HORNING, LETTERS OF, in the law of Scotland, were the first step of the old process under which the arrest of a debtor was competent. By a legal fiction, no person could be incarcerated for a civil debt. But on the application of the creditor, a charge or legal demand was made upon the debtor to pay within a certain period, and if this was disregarded, the debtor was denounced at the market cross of the sheriffdom as a rebel to the king, as having disobeyed the royal command to make payment to the creditor. This ceremony was performed by messengers-at-arms after three several blasts of the horn. The instrument which embodied the charge to pay, and the command of the sovereign to proceed to denunciation and horning, was from the ceremony above described, and from the form in which it was framed, called Letters of Horning; and on the execution and registration of these, letters of caption followed, in virtue of which the creditor could proceed to apprehend and incarcerate his debtor. These cumbrous and complicated forms, though by no means abolished, were practically superseded by the provisions of the Personal Diligence (Scotland) Act, 1 & 2 Vict. c. 114, ss. 5 & 6.

HOROCLOGY (Gr. *hora*, 'a defined portion of time,' and *logos*, 'a discourse'), a term usually applied

to signify that science which regulates the action of the various machines used for the purpose of measuring time. [CLEPSYDRA and SUN-DIAL.] The practice of measuring time by hours, minutes, and seconds is of comparatively recent date; yet we find improvements early made in the computation of larger periods of time, by observations of the heavenly bodies. The progress of astronomy disclosed many sources of error that had been overlooked in the movements of the more conspicuous planets, when these movements were employed to mark intervals of time. Thus time was anciently divided into years, according to the motion of the sun among the constellations; into months, according to the motion of the moon relatively to the sun's place in the heavens; and into days, by the alternate light and darkness caused by the rising and setting of the sun. The earliest attempt made to divide the day itself was by tracing the shadow of an upright object, which gave a rough measure of time by the variations of its length and position, or, in other words, by means of the sundial. Hour-glasses belonged to this plan of determining gross amounts of time by a rough and ready mechanism, and the clepsydra was contrived for the same purpose. In the former case the running of fine sand from one vessel to another was the method adopted, and in the latter the measurement of short periods of time was effected by the quantity of water dropped from one vessel into another.

History of Watch and Clock Making.—The origin of clock-work is involved in great obscurity. Some maintain that clocks were invented by Boethius early in the sixth century; and that Pope Paul I., about 760, made a present of one to Pepin, king of France, which was then supposed to be the only clock in the world; others give the honour to Pacificus, of Verona, in the ninth century, and assert that the striking part was invented by the Saracens. It is certain that a curious clock was sent to Charlemagne from the Caliph Haroun al Raschid, which the historians speak of with admiration. Mention is made of a clock having been put up at Westminster in the year 1288, during the reign of Edward I. Striking clocks were known in Italy as early as the latter part of the thirteenth or the beginning of the fourteenth century.

De Wyck's clock, made in 1364 for the emperor of Germany, was a large striking clock, going for one day, and with one hand (the hour hand), and much the same as many old church clocks at present. It had two pallets worked by a crown-wheel, and two weights on a lever to regulate the movement to time. (See Plate 1, figs. 1, 2, 3.) It appears there is still a clock in existence at Dover Castle, bearing the date 1348, earlier by sixteen or more years than that of De Wyck. In 1484–85 Waltham made a balance clock for astronomical observations. In 1560 Tycho Brahe had four clocks which indicated hours, minutes, and seconds, the largest of which had only three wheels, one having 1200 teeth. In 1577 Moesthin had a clock, whose beats enabled him to determine approximately the apparent diameter of the sun. At what time watches or small clocks were introduced, by the use of a mainspring instead of a weight as the moving power, is uncertain. The earliest portable timekeeper of which any account has been given, is one dated in 1525, made by Jacob Lech of Prague, and a good many years in the pos-

session of William Beckett, a London clockmaker. Galileo's discovery of the isochronism of the pendulum paved the way for the introduction of pendulum clocks; this was the great epoch in the history of horology, and it is probable that both Galileo and Huygens had constructed pendulum clocks before 1648, though some writers say that Richard Harris made a pendulum clock a few years earlier, viz., in 1641. In 1676 Barlow, a London clockmaker, invented the repeating mechanism by which the hour last struck may be known by pulling a string. Several artists followed in the same line, particularly Quare, in London, and Julien le Roy, Collier, Larçay, Thiout, &c., on the continent. Clocks soon afterwards were made to show not only mean but apparent time.

Clement, a London clockmaker, invented in 1680 the anchor escapement, which was a great improvement on the crown-wheel before in use; he also introduced the practice of suspending the pendulum by a thin and flexible spring. (Fig. 4, Plate 1.) The next important improvement was the adjustment of the length of the pendulum to the varied effects of heat and cold. In 1715 George Graham, by substituting a jar of mercury for the pendulum ball, succeeded in retaining the point of suspension and the centre of oscillation at an equal distance from each other. The principal objection to this pendulum is its liability to breakage, of which its author felt the full force, and in consequence suggested the idea of the compensating expansions of different metals, as a substitute for his form of pendulum. John Harrison immediately turned his attention to the subject, and by dint of perseverance overcoming all the difficulties of his humble and retired situation, not only astonished the world by his improvements in horological machines, but absolutely constructed with his own hands a timekeeper which determined the longitude within such limits as to procure him the parliamentary reward of 20,000*l*. [HARRISON.] Although the anchor escapement previously mentioned was a great improvement upon all that had preceded it, still it was subject to objections, not one of the least of which was that at every vibration a considerable recoil took place. The inconveniences of this escapement were, however, removed (about the same time with the invention of Harrison's pendulum, 1726) by Graham, who introduced what is called the dead-beat escapement, which is both simple and effective. (Fig. 7, Plate 2.) The dead-beat escapement is adopted in timekeepers when great accuracy is required. Other inventions, as the *detached escapement*, the *pin-wheel escapement*, the *gravity escapement*, in various forms and in different degrees of efficiency, have been only partially adopted. The names of Harrison, Cumming, and Mudge, whose several contrivances are shown in the Plate, are associated with contrivances of this kind.

Description of the Eight-Day Clock.—The woodcuts employed to illustrate clock and watch work are so very embarrassing to non-technical readers, that we will endeavour to give a verbal description of an eight day-clock:—There are two barrels containing springs, one to give motion to the train of wheels called the 'going' train, and the other to the 'striking' train. (See figs. 4, 5, 6, Plate 1, and fig. 6, Plate 2.) The first of these springs moves a wheel called the main wheel, which in its turn acts upon several

other wheels, whose time of rotation corresponds with that of the minute and hour hand. The last wheel of this system acts upon two little levers or pallets, which give an alternating motion to the pendulum of the clock. A *fusee*, which is a kind of spiral system of grooves, is fitted to the main wheel, and enables the main wheel to maintain an equable motion during the varying pulling force of the spring. All the above-named wheels belong to the *going* train. There is a somewhat similar train belonging to the *striking* action; but the teeth of the wheel, instead of being so cut as to facilitate the movement of two index hands, act upon certain pins and levers which move the hammer belonging to the bell: this part of the mechanism is exceedingly beautiful, especially when the clock strikes the quarters.

The action of such a clock, then, is this:—Once in eight days the clock is ‘wound up,’ which consists in coiling up the going spring very tightly in its barrel. Where the actuating force of the mechanism of the clock is a descending weight, as in the old gravitation clocks, the fusee and spring are substituted by a cylindrical barrel and a cord which is wound up on its circumference. In its efforts to uncoil itself, the spring forcibly pulls round the main wheel, with which it is placed in connection; and the fusee causes this motion to continue steadily and equably. As the main wheel cannot rotate without moving the train of wheels to which it is connected, these also rotate, with a velocity depending on the number of teeth acting upon each other. In two of the wheels these numbers are so regulated that the wheels revolve in one hour and twelve hours respectively; and the axes of these wheels serve as axes for the minute and hour hands. Meanwhile the second spring gives motion to the *second* train of wheels, which are so connected with the going wheels as to enable the bell-hammer to be moved at the proper time. One of the many kinds of pendulum, concealed behind or within the clock, is set in motion by one of the wheels, and by its isochronous or ‘equal-timed’ vibrations, tends to give regularity to the movements of the wheels generally. The gradual perfection of clocks required also improvements in the pendulum. No simple pendulum, however, can be depended on for an accurate timekeeper, for the isochronism of vibrations of the pendulum depends on its being always of the same length. Now a cord always contracts or expands with changes in the atmosphere, and a rod with cold or heat. To overcome these defects in the pendulum, the compensation pendulums of Graham and of Harrison, already referred to, were invented.

Large Pendulum Clocks.—Turret-clocks differ from other machines employed for measuring time, not only in their greatly superior size, but because such a clock is frequently required to indicate the time upon as many as four different dials, on the four external faces of the tower in which it is mounted. This is accomplished by placing the clock near the centre of an apartment, and causing the motion of the axis, which under ordinary circumstances would carry the minute-hand (which revolves once in an hour), to be transmitted by bevel-gear to a vertical rod, the opposite end of which carries a horizontal bevel-wheel nearly on a level with, and situated centrally in reference to, the four external

dials. The motion of this central wheel is communicated by four vertical bevel-wheels of the same size and number of teeth, ranged round its circumference, to four horizontal rods, the opposite ends of which, passing through the several dials, carry the four minute-hands. At the back of each dial is a series of wheels and pinions, imparting motion to the hour hand, which revolves once in twelve hours. In a turret-clock, the moving power is supplied by the descent of a weight, regulated in the case of the movement, or going train, by the oscillations of a large pendulum, and in that of the striking train by the resistance of the air to the rapid revolutions of a fly or fan set in motion by the wheel-work. Owing to the necessity for using a very heavy hammer to strike the hours in a church-clock, the power required for working the striking-train considerably exceeds that of the going train.

The escapement in this, as in any other form of horological mechanism, is of the highest importance, and the performance of the piece depends much upon its soundness of principle and excellence of workmanship. An escapement should possess the following qualities:—Being intended to keep the pendulum in motion, it should supply the necessary force with absolute regularity, so that the pendulum should vibrate to the same distance at all times; irregularities in the power transmitted through the wheel-work should not take effect upon the pendulum. The latter should be free to exercise its own peculiar governing power, and obey those laws of motion upon which the excellence of this form of movement depends. The form of escapement known as the *remontoir* or *rewinder*, has found much favour among the improvers of turret-clocks. There is an application of the *remontoir* principle known as the *gravity* escapement, referred to above, in which the weight raised acts directly upon the pendulum, the ordinary escapement-wheel being dispensed with. In the London Exhibition, 1862, a large clock was shown by Messrs. Cooke & Sons, of York, with this latter form of escapement. (See Plate 4.) In connection with this subject a word may be said about the dials of turret-clocks. The established form of dial for these is a sheet of copper made convex, to preserve its shape, and this is just the worst form which a perverse ingenuity could contrive for the purpose. The minute hand is thrown off from the surface by the convexity, and if it is bent to avoid parallax, it presents a poor appearance. Dials should be slightly concave, and the material may be of slate, stone, or cast iron.

Musical chimes require the addition of another train of mechanism to that of the ordinary turret-clock, somewhat like that which constitutes the striking train. The mechanism of the chimes very nearly resembles, on a large scale, that of a musical snuff-box; levers, connected with hammers which strike upon a series of bells, being substituted for the springs which in the musical snuff-box are caused to vibrate by the projecting pins on the revolving barrel.

In the Royal Exchange clock, London, made by Mr. Dent, many improvements have been introduced. There is a simple but strong cast-iron framing, which enables the several parts of the clock to be put together with less strain than usual. The wheels for the striking train are made of cast iron; more

durable and less costly than the usual gun-metal wheels. The wheels of the going train, smaller and requiring to be more nicely adjusted than those of the striking train, are made of hammered brass. Hollow iron drums are used instead of wooden cylinders for the driving barrels, and wire instead of hemp or ropes for suspending the weights. It was required, by the terms of contract, that this most admirable clock should have a compensation pendulum, and that it should be so constructed as not only to show perfectly correct time upon the dials, but also to tell it with accuracy by making the first stroke of the hour upon the bell true to a second. This object is attained by a beautiful arrangement of mechanism. In this clock has also been introduced a skilful contrivance for maintaining the motion of the wheels during the time of winding up, which was invented a few years since by Professor Airy for the clock-work of the great Northumberland telescope at the University of Cambridge.

Electro-Magnetic Time-Pieces.—Koosen, of Dresden, has recently introduced a peculiar construction and arrangement of what he terms a galvanic chronometer, with centrifugal regulator, which consists of an application of galvanic agency to the works of a chronometer, and of a regulation of the movements of the latter by a device for controlling the speed of the electro-magnetic machine. The improved electro-magnetic machine, as here applied, is one of rotation, and has this important property, that the accelerating force acts almost uniformly in all phases of its rotation, and that the acting power cannot be interrupted by any intervals of suspension. This is effected on the principle that the several electro-magnets, forming part of the machine, are not magnetized simultaneously, but successively; so that no actual impediment of the galvanic current can ever occur, but the current flows from the coil of one electro-magnet, after the latter has exercised its influence on the corresponding soft iron bar, directly into the coil of a second magnet, which begins to act in a similar manner to the first, on a second soft iron bar, and so the action continues.

On a brass plate, *A* (Plate 5, figs. 1 and 2), of about six inches in diameter, provided with three elevating screws, *B*, are permanently fitted three electro-magnets, *C*, with cylindrical arms, so that their six poles are directed upwards, each of which is about three quarters of an inch in diameter, the series of poles forming a regular hexagon, all six of which lie in the same horizontal plane. Both arms of the electro-magnet can be screwed off from their connecting plate, *D*, by means of short screws at *E*. The wire for the coil must be selected as thin as possible, about 1-100th to 1-200ths of an inch in diameter; it should be well covered with silk, and strongly varnished. Immediately above and as close as possible to the poles of the electro-magnets, rotate two soft iron bars, *F*, with cylindrical ends; they are screwed on to a brass pin or axle, *G*, at right angles to each other, so that their four ends or poles form a regular rectangle in a horizontal plane. The brass pin on each terminates below in a hard steel point, resting on a conical hollow, also made of hard steel, whose upper end is also provided with a steel spindle, running in brass bearings, and immediately below the spindle it carries a wheel,

which transmits the rotation of the axle by means of a system of toothed gearing to the hands of a clock, and so indicates the number of rotations of the machine or the hour upon the dial. The entrance of the galvanic current into the different coils is regulated by the commutator, *H*, consisting of a ring or disc of mahogany permanently fixed concentrically to the axle of the machine, and kept in this position by a brass bracket or arm. The upper surface of the ring is inlaid with twelve plates of silver, *a*, strongly gilt, and separated from each other by small interstices. Each plate is provided, on its outer edge, with a small hook, *b*, of silver wire, whereon to fasten one end of the wire of the coils, in such order and succession as is required by the relative positions of the magnet poles and the corresponding poles of the rotating soft iron bars. The other ends of the wire coils are permanently connected with each other, and with one pole of the galvanic battery; whilst the other pole conducts the current into the axle, *G*, thence into a brass rod, *I*, fastened to the axle at right angles, and carrying a mass of the finest gold wire, which glides easily over the different sections, *a*, of the commutator, and in this manner, as the machine rotates, guides the current into the different coils.

To produce a uniform velocity of the rotation, a regulator is fixed on the axle, *G* (fig. 2.), which consists essentially of a steel rod, *K*, through whose centre of gravity passes a steel pin or axle, *L* (fig. 3), provided at the end with conical points of hard steel, carried in fixed screws, *M*, so that the whole rod may revolve round its centre of gravity with the least possible amount of friction. The bearings, *M*, in which the axle, *L*, of the rod rests, are let into the circumference of a brass ring, *N*, which is fixed concentrically upon the axle of the machine, and rotates with it. Thus the latter will, at the smallest velocity of rotation, assume a horizontal position by the action of its centrifugal force, as soon as the brass balls at the end of the steel rod, *K*, are brought in such a position that the centre of gravity of the whole rod passes through its axis of suspension. On its lower end the steel rod carries a brass arm, *O* (fig. 2), tipped with gold or platinum, whose point, while the machine is not in motion, rests against a thin and slightly feathering plate of platinum, *P*. The galvanic current enters through the main vertical axle into the brass ring, *N*, whence it passes at *S* into the steel spring, *A*, thence, at *Q*, into the rod, *K*, from there, at *O*, into the platinum plate, *P*; a fine platinum wire, *T*, connects this plate with the brass rod, *I*, which carries the gold wire sliding on the metallic sections of the commutator, and so the regulated current enters the different coils in succession, and sets the instrument in motion.

Astronomical Clocks.—These are simply standard clocks most frequently used by astronomers, and especially contrived for them. A good astronomical clock should be as simple as possible in construction, and all resources of practical science should be drawn upon to render its parts in perfect accordance with theory. Remontoir or gravity escapements have been much favoured for these clocks by the theorist, but no perfectly successful gravity escapement has yet been introduced. But the art of horology would be incomplete unless there were some standard, independent of all mechanical contrivances, to which

all may be referred, and by which the errors of each time-keeping instrument may be corrected.

The movements of the heavenly bodies are still, as of old, the only standard for a general measurement of time, affording as they do marks of unvarying certainty, to be read by all alike; and clocks and other mechanical contrivances are individual and imperfect measures of the intervals, to be trusted only until there is a new opportunity of comparing them with the certain and public signals of the heavens. These signals can, however, only be accurately read by persons furnished with the proper apparatus, and informed sufficiently in its use. This is done in observatories, and there are now in most parts of this country sufficient opportunities of setting clocks by a communication more or less direct with these establishments. The time which a clock ought to mark is *mean time*, the definition of which will be found in the article DAY. The *mean time* at any place depends on the longitude. Supposing a clock to be set to Greenwich mean time, a clock keeping mean time of any place will be fifteen minutes faster for every degree of longitude east of Greenwich, fifteen minutes slower for every degree west. Since the introduction of railways, clocks are usually set, within Great Britain, to Greenwich mean time.

The methods by which time is determined in observatories belong to the details of practical astronomy. For the more ready transmission of correct time to the public, there is at Greenwich Observatory, as well as at some other places, a ball which is dropped by means of electricity precisely at one o'clock. Recently, however, there has been invented a most ingenious device by which public clocks in a town can be kept at every instant in perfect agreement with the mean-time clock in the observatory. This is effected by an electric connection invented by Mr. R. L. Jones of Chester, on the suggestion of Mr. Hartnup, the astronomer of the Liverpool Observatory. (For a description, see ELECTRIC CLOCK.) The earliest public application of it was to the town-hall clock in Liverpool, when for the first time was seen the curious spectacle of a great clock with works nearly 100 years old keeping time with astronomical accuracy. In the same way, a clock in the castle of Edinburgh, by whose mechanism a gun is fired precisely at one o'clock every day, is controlled by the mean-time clock in the observatory on the Calton Hill.

Mechanism of a Watch.—A pocket watch is very similar in principle to a good clock, except that the regulation of the former is by a balance and spring, and that of the latter by a pendulum. It would be a matter of some difficulty to determine what artist first reduced the portable spring-clock to the dimensions of a watch to be worn in the pocket. The small clocks prior to the time of Huygens and Hooke were very imperfect machines; they did not even profess to subdivide the hours into minutes and seconds until the invention of the balance-spring, which is to the balance what gravity is to the pendulum, and its introduction has contributed as much to the improvement of watches as did that of the pendulum to clocks. The honour of this invention was warmly contested by the last-named individuals previous to 1658; but so far as priority of publication is concerned, the honour is due to Dr. Hooke.

When clocks and watches had acquired a certain degree of accuracy in their performance, the time lost in winding up (especially when it had to be done every twenty-four hours) became a matter of importance, and there have been several inventions to remedy this evil. By Huygens the clock was kept going while winding up by means of an endless cord. The *forcing spring* gives another plan, in which a lever is so adjusted as to allow the wheels free movement while the spring-barrel is being acted on by the key. But Harrison's contrivance for the same purpose is the one now in general use, both in clocks and watches, and is admirably adapted to the purpose, as it requires no attention from the person who has to wind up the machine, but is always in its place, and ready for action the moment the operation of winding is commenced. It is generally called the *going fusee*, but a better name for it is *maintaining power*. The principle of its action depends on the mode in which the fusee is fixed into a socket connected with the main wheel, so as to allow the wheel and the fusee to rotate independently of each other when required.

Watches and Chronometers.—These have a spiral spring instead of a weight for their maintaining power. Watches seem to have been made as early as the sixteenth century, though Huygens in the seventeenth was the first discoverer of the important law respecting springs, which he enunciated in the well-known words, *ut tensio sic vis*—the force of a spring varies as the bending of it. The most simple form of mainspring arrangement for a clock or watch is that where the spring, which is a narrow strip of tempered steel, has its inner end attached to the arbor, which ends in the winding square having a ratchet set on it with the click in the clock-frame. The other end of the spring is fixed to the barrel, which is the great wheel of the clock or watch. And one advantage of this is, that there is just the same pressure on the train, or the wheels and pinions placed between the uppermost frame-plate and dial, when you are winding up as at any other time, and no going barrel apparatus is wanted. But it will be obvious, that by virtue of the rule *ut tensio sic vis*, there must be a much greater force on the train when the watch is wound up, than when it is nearly run down. Fig. 1, Plate 2, shows the general arrangement of a watch, as presented in elevation. The barrel and fusee will be recognized at once. The fusee is a sort of grooved cone, with a concave section; the more rapid swell towards the thick end is required because one turn of the fusee, when the chain is at that end, takes much more off the barrel than at the thin end; and on the assumption that the force of the spring varies as its tension, the radius of the cone must increase more rapidly, in order to make the increase of leverage keep pace with the decrease of the force of the spring, as it unwinds with an increasing velocity off the thick end of the fusee. The fusee itself is connected with the great wheel by a ratchet and click and going ratchet, parts which may be seen in fig. 1, and in the ground plan, fig. 2. Something is also required to prevent the watch from being over-wound, or the chain strained so as to break. This is done by means of a hooked lever set on a hinge in the upper frame-plate; and when the watch is nearly wound up, the chain

moving upwards, reaches this lever, and raises it in such a position that its hook catches hold of the long tooth projecting from the thin end of the fusee, and thus the winding is stopped without any strain by the sudden check. In watches without a fusee, the apparatus for preventing them from being overwound is different; it goes by the name of the Geneva stop. Its principle is simply this: If two wheels work together, of which one has the spaces between some two or more adjacent teeth filled up, it is evident that that wheel cannot be turned quite round. It will be the same thing as if one of the wheels is only a cylinder with a single tooth in it, and the other has a certain number of notches not going all round, through which the teeth can pass. The other parts of a watch do not differ from those of a clock, except in size, and the position in which the parts are arranged to bring them within the circle of the dial, until we come to the escapement, and there a different state of things arises.

The word *escapement* is a term applied to a combination of parts in a clock or watch, which has for its object the conversion of the circular motion of the wheels into a vibratory motion, as exhibited in the pendulum. The component parts include the scape-wheel, the pallets with their arbor or axis, and a bent lever attached thereto, called the crutch, which last piece maintains the motion of the pendulum, see fig. 4. In a watch this combination consists of the scape-wheel, together with all those parts lying between it and the balance, and which are concerned in converting the circular motion of the wheels into the alternating one of the balance. The pallets act upon or between the pointed teeth of the scape-wheel by a reciprocal or oscillatory motion.

The balance of a watch moves (figs. 4, 5, 6, and 7, Plate 3), sometimes through a space equal to 270° , while a clock pendulum only vibrates through 4° or 5° . The balance being common to all watch escapements, it will be proper first to describe that, and the conditions to which it is subject. The two equal arms with equal weights at each end are really a balance just as much as the wheel, which is commonly used as the more convenient form. The compensation balance consists of two arcs attached by one end to a cross connecting bar, having the other end free to move. These arcs being composed of thin strips of steel and brass, the bars being outside, are so affected by the heat as to curve inwards, carrying the weights nearer to the centre, and thus diminishing the effective diameter of the balance, at the same time that the strength of the spring is relaxed. But the centre of gravity of these arcs or bows does not approach or recede from the centre in a straight line. The decrease of temperature straightens the arcs, the increase curves them in greater degree. The metals forming the compensation balance of the watch are generally soldered together by pouring melted brass round a solid steel disc, and the whole is afterwards turned and filed away till it only leaves a cross bar lying flat in the middle, and the two portions of the rim lying edgewise. The first person who practised this method of uniting them, appears to have been Thomas Earnshaw, whose skill brought the chronometer to the state in which it has remained for the last eighty years with scarcely any alteration. Kulberg's balance (figs. 5 and 6, Plate 3) is a contrivance, the

distinguishing feature of which is that the rim, instead of being upright, is saucer-shaped, causing the balance to flatten itself in the cold. This tendency is promoted by making the radial bar compound, and increasing its action by tripling it laterally, so that the term 'gridiron balance' has been erroneously given to it.

The Keyless Watch.—This was first introduced in Switzerland, and, as applied to the going barrel of the Swiss watch, is a comparatively simple affair, consisting merely of two or three steel wheels actuated by a button, the stem of which passes through the pendant, and has cut upon its end a bevelled pinion. The arbor of the going barrel being stationary, except when the winding of the watch takes place, does not necessitate any contrivance for throwing the winding mechanism out of gear, and only an arrangement is needed for connecting the hands with the wheels when it is desired to set the watch to time. It is unnecessary to enter into further detail respecting this mode of construction. Figs. 1, 2, and 3, Plate 3.

The method of a keyless watch possesses a considerable advantage besides the mere convenience of being independent of a key; for as there is no occasion to open the watch, the case may be made to fit more closely, and the air more completely excluded. Consequently it will go longer without cleaning, and the thickness and cost of a double back to the case are saved.

The number of clocks imported into the United Kingdom in 1867 was 251,355, valued at 263,291*l*. Nearly the whole came from the United States, France, and Holland. In the same year, 11,454 clocks, valued at 20,425*l*., were exported, the majority being sent to Australia and India. Of watches received in 1867, almost exclusively from France, there were 119,697, valued at 189,183*l*.; and exported, chiefly to Egypt and the Channel Islands, 9040, of the value of 61,141*l*.

HOROLOG'GIUM (Constellation), the Clock, a southern constellation of Lacaille. It is cut by a line passing through Canopus to the southern part of Eridanus.

HORREBOW, PETER, a Danish astronomer, was born in the year 1679. After studying medicine for several years, he became the pupil of the celebrated mathematician and astronomer Olaus Roemer, whom, in 1710, he succeeded as professor in the University of Copenhagen. Horrebow died at Copenhagen in 1764, at the advanced age of eighty-five years, leaving a considerable number of works.

HORROCKS, JEREMIAH, often written Horrox, an astronomer who has obtained a lasting celebrity, though he died at the age of twenty-two, or thereabouts. Jeremiah Horrocks was born, it is supposed, about the year 1619, at Toxteth, near Liverpool. His father, a man of moderate means, placed him, before 1633, at Emmanuel College, Cambridge, and there he soon began to turn his attention to astronomy. During the time in which the Court and Parliament were occupied in the disputes which led to civil war, four men, three of them very young, and all personally acquainted with each other, were employed in advancing the theory and practice of astronomy. Three of them died very young, and their names had almost perished, and would probably

have been lost, but for the more than usual talents of Horrocks. Though the papers which Horrocks left behind him contain many good observations and ingenious remarks, he must now be considered as known by two particulars. He was the first who saw Venus on the body of the sun, and who remarked that the lunar motions might be represented by supposing an elliptic orbit, provided that the eccentricity of the ellipse were made to vary, and an oscillatory motion were given to the line of apsides. Newton afterwards showed that both suppositions were consequences of the theory of gravitation.

The account given by Horrocks of his observation of Venns, November 24, 1639, entitled 'Venus in Sole Visa,' was printed by Hevelius at the end of his 'Mercurius in Sole Visus,' published at Danzig in 1662. The remainder of the works of Horrocks were published by Dr. Wallis, London, 1672, some copies bearing the title-page 'Opera Posthuma,' and others 'Opuscula Astronomica.' The death of Horrocks took place January 3, 1641 (old style).

William Crabtree, who died a few months after his friend Horrocks, at a very early age, was a clothier at Broughton, near Manchester, and many of his observations were printed by Wallis in the work above cited, and afterwards in the discussion about Gascoygne, presently to be mentioned.

William Milbourn, curate at Brancespeth, near Durham, was, according to Sherburne, well versed in algebra, having extracted the approximate root of an equation of the fifth degree before he had seen Harriot's work. In astronomy he had, by his own observations, detected the errors of Lansberg's tables, and verified those of Kepler.

William Gascoygne, of Middleton in Yorkshire, was killed, at an early age, fighting for Charles I. at Marston Moor. He invented methods of grinding glasses, and Sherburne states that he was the first who used two convex glasses in the telescope. When Auzout announced, in 1666, his invention of the micrometer, Richard Townley, nephew of Christopher Townley, presented Hooke with a modification by himself of a similar instrument made by Gascoygne; and it appeared, from a letter written by Crabtree to Horrocks, that Crabtree had seen Gascoygne use an instrument of the kind. It appears now to be generally admitted that Gascoygne was the original inventor of the wire micrometer, of its application to the telescope, and of the application of the telescope to the quadrant; but that the invention was never promulgated, even in England, until the undoubtedly independent inventions of Auzout and Picard had suggested their publication.

HORS DE COMBAT, a French term, meaning 'out of the fight,' disabled. When a combatant or an army is incapable of further action, completely beaten, they are said to be 'hors de combat.'

HORSE, the family of *Equidae*. Cuvier places the horse in the solipedous section of the Pachydermata, quadrupeds which have only a single toe on each limb apparent, incased in a hoof, although there are on each side of the metacarpus and metatarsus stylets which represent two lateral toes. Cuvier considers that one genus only is comprehended in this group or family, viz., *Equus*, the characters of which he gives as follows:—In each jaw six incisors, which in youth have their crowns hollowed by a pit, six molars

on each side above and below, with a square crown, showing four crescentic pits, besides which, in the upper teeth is a little disc on the internal edge. The males, moreover, have two small canine teeth in the upper jaw, and sometimes in both jaws: these are almost always wanting in the females. Between these canines and the first molar is a vacant space which corresponds to the angle of the lips; it is here that the bit is placed, by means of which alone man has come to subdue these vigorous quadrupeds. The stomach is simple, and of moderate size; but the intestines are very long, with an enormous cæcum. The teats are inguinal.

Gmelin, in his 'Systema Naturæ,' gives a species of horse which he calls *Equus bisulcus*, the *Equus pedibus bisulcis* of Molina, 'Hist. Nat. Chili.' This was a Llama, and Gmelin was deceived by the term *Equus* used by Molina. We shall pass over as unworthy notice all the various fabulous kinds of horses, described by Aldrovandus and others.

Mr. Gray considers the *Equideæ* as consisting of two genera, viz., *Equus* and *Asinus*, and many modern zoologists have adopted his views.

In *Equus*, the mane is long and flowing, the tail densely covered to its root with long hair, the hinder legs as well as the fore-arms are furnished with warty callosities. In the coat of the horse, moreover, there is a disposition to the formation of small round spots or rings of a different shade or hue from that of the ground; and this is the case whether the general colour be black, chestnut, or gray.

In *Asinus*, the mane is short, meagre, and upright; the tail is furnished with long hair only towards its extremity; there are warty callosities on the fore-arms, none on the hinder limbs. The ground-colour of the coat is more or less whitish (in the wild species), always with a distinct dorsal line of a dark tint, with stripes or bands of the same colour more or less pervading the body and limbs.

Col. H. Smith separates from the genus *Asinus* those species which are banded like the Zebra, and applies to them the title of *Hippotigris*, but this cannot be considered as a generic section.

Genus *Equus*.

The Horse (*Equus caballus*), in a state of domestication, varies in size from the massive and gigantic dray horse to the diminutive Shetland pony. Its colour is also as variable as its size, ranging through white, cream-tint, gray, mottled, iron-gray, dun, bay, chestnut, black, &c. It, moreover, presents us with different strains, how produced originally it is not easy to say; certainly the high-blood racer and the slight meagre Arab present strong contrasts in their contour and capabilities to the heavy Flanders horse and the huge dray horse rising from 18 to 20 hands high at the withers. Between these two extremes there are numerous intermediate breeds, some adapted for the chase, some for carriages and light-wheeled vehicles, some for the traveller's saddle, and some for farm-house labour. Ponies again, a small variety of the horse, show differences of a like nature—some are finely formed, full of mettle and courage, and show high blood—others are clumsy and ill-formed, though strong and hardy; and the intermediate gradations are numerous.

It would appear that the horse was first domesticated or reclaimed in the east, that it was brought

with the hordes migrating westward from Asia, and was thus introduced into Arabia and Egypt, and that we must look to the deserts north of Hindustan and Persia as its cradle, or at least as the locality in which it first became subject to man.

It seems, from their fossil remains, that various species of horse were once spread over Europe, Asia, and even North and South America. Fossil remains of a horse were brought home by Captain Beechey from the mudcliffs of Eschscholtz Bay, in North America; they were found associated with those of the mammoth and fossil ox. To this we may add Mr. Darwin's observation, that 'horses' bones mingled with those of the mastodon have several times been transmitted for sale from North America to England; but it has always been imagined, from the simple fact of their being horses' bones, that they had been accidentally mingled with the fossils.' In South America Mr. Darwin found the fossil tooth of a horse, together with one of the extinct toxodon at Santa Fé, in the red clayey stratum of the Pampas, and also part of another tooth at Bahia Blanca, imbedded with numerous other remains of extinct *Edentata*, in a beach which was covered at spring tides. In the caverns of Minas Geraes, a mining district of Brazil, the relics of a species of horse have been found in considerable abundance.

With the mastodon, the megatherium, the mylodon, &c., the indigenous horse has long disappeared from America; but in the present day man has refilled its place by the importation of the domestic stock from Europe, and now on the pampas and the prairies troops of wild horses scour the plain in perfect freedom, the descendants of a domestic race born and reared in slavery.

Formerly, according to Oppian and Pliny, wild horses existed in Scythia, Thrace, along the Danube, and even in Europe: according to Varro, they were found in Spain. Oppian says that wild horses existed in Ethiopia; and according to Julius Capitolinus, it was from Africa that the Gordianus procured eighty wild horses for the spectacles of Rome. Leo Africanus states that wild horses inhabited the deserts of northern Africa, an assertion to which Pennant alludes.

Genus *Asinus*.

Of this genus one species has been domesticated from the earliest ages, and is now spread over nearly all the world. We allude to the Ass (*Asinus vulgaris*), the subdued descendants of one of the wild species which roam the great Asiatic deserts. We may here observe that the members of the present genus are comparatively numerous, and are divided between Asia and Africa.

Some confusion appears to obtain among the Asiatic species of *Asinus*, which requires yet to be cleared up. The following is the result of our researches:

1. The Dziggetai, Djigetai, &c. (*Asinus hemionus*, Pallas), the great wild ass, or Ghoor-Khur, characterized by a simple dorsal line, without a shoulder-stripe. Locality, Persia, Bucharia, Tartary, Tibet, South Siberia, and India.

2. The Khur, or wild ass of Persia, described by Sir Robert Kerr Porter (*Asinus Hamar*, Col. H. Smith). Mane black, no dorsal stripe or cross; smaller than the Dziggetai, with the head heavier in proportion; swift.

3. The Kiang (*Equus kiang*, Moorcroft), described

by Moorcroft, and which he says is decidedly not the wild ass (dziggetai) of Scinde. Locality, the eastern parts of Ladakh. Colour light reddish chestnut; jaw, neck, legs, and belly white; mane dun; ears moderate; height about 14 hands; swift. Very little is known of this species.

4. The Onager, Koulan, or Wild Ass (*Equus onager*), the reputed origin of our domestic race. [Ass.] A distinct dorsal stripe and crossbar over the shoulder. In winter the coat of this species becomes fine and undulated. Gregarious, migratory, fleet. Locality, the country of the Khirgis, the Bucharians and Kal-mucs, and northern Persia. It is also found west of the Euphrates, and in Syria, Arabia Petrea, and Northern Africa.

5. The Yo-To-Tzé (*Asinus equulus*, Colonel H. Smith). The specimen Col. H. Smith describes and figures, was said to have come from some part of Chinese Tartary. Height about three feet. General colour reddish clay; tips of the ears, mane, and long hair on the tail, black; black dorsal line and broad cross bar; three or four cross streaks over the knees and hocks.

Perhaps the Koomrah of North Africa and the Wild Ass of the same region are identical. The Koomrah figured by Col. H. Smith is more asinine than equine in appearance.

The African species are:—

1. The Zebra (*Equus zebra*). Locality, mountain districts from Caffraria eastward to beyond Mozambique; gregarious.

2. The Dawu, or Burchell's Zebra (*Equus Burchellii*). Locality, the vast plains of Southern Africa north of the Gariap. Harris states that it is never found south of that stream.

3. The Quagga (*Asinus quagga*). Locality, the plains of South Africa.

4. The Congo Dawu, or Hippotigris of the ancients, and exhibited in the Roman spectacles. Locality, Abyssinia and Nigritia. The legs are not striped to the hoof as in the zebra. This species is termed by Col. H. Smith *Hippotigris antiquorum*. If an admitted species, it may stand in the present arrangement as *Asinus hippotigris*. It is closely allied to the dawu.

5. The Isabella Quagga (*Asinus Isabellinus*), a wild ass of a pale yellow colour, seen by Le Vaillant in large herds in South Africa.

Hybrids.

The ass and horse breed together. The offspring of a male ass and a mare is termed a mule—of a female ass and a horse, a hinney. The latter is valueless; not so the former. Mules have been produced from the mare and the quagga. The following mules of the equine family have been produced and reared in the gardens of the Zoological Society:—

1. Mule between Burchell's dawu (male) and ass (female). 2. Mule between common zebra (male) and ass (female). 3. Mule between dziggetai (male) and ass (female); fleet and beautiful. 4. Mule between zebra and Exmoor pony; the mule very little striped about the legs. 5. Mule between zebra and dziggetai.

We can here only briefly allude to a strange physiological fact, that the characters of the male parent of the mother's first progeny show themselves in her subsequent offspring by other males. A young mare

belonging to the earl of Morton, after producing a female hybrid by the quagga, had afterwards a filly and then a colt by a fine black Arabian horse. Both resembled the quagga in the dark line along the back, the stripes across the forehead, and the bars across the legs. In the filly the mane was short and stiff; in the colt it was long, but so stiff as to arch upwards and hang clear of the sides of the neck. In other respects they were nearly pure Arabian.

The fossil remains of *Equidae* are abundant and widely spread through the pliocene period of the tertiary series. The species appear to have been numerous.

Economical Uses and Diseases of the Horse.—The horse is naturally herbivorous; his thin muscular prehensile lips, his firm and compressed mouth, and his sharp incisors, are admirably adapted for the purposes of seizing and cropping the grass; so flexible, indeed, are the lips, that the horse can pick up with ease the last few grains of oats in the manger. The crushing power of the grinders is extraordinary, the muscles of the lower jaw being of vast volume and energy; hence vegetable fibres, grass, grain, &c., are comminuted to a pulp. Nevertheless, it is doubtful whether in his natural condition the horse would select grain, were it obtainable, in preference to grass. The grinders in time become much worn by its attrition, and in many old horses the grain is only partially crushed, and consequently affords little nutriment. Hence, as a general rule, grain should be bruised before being put into the manger.

As the age of a horse is ascertained by an inspection of its teeth, or rather its incisor teeth called nippers, a knowledge of the process of dentition, and of the exact character of the incisors at different periods of a horse's life, is indispensable to the veterinarian, the dealer, and the purchaser. But let not the purchaser, however knowing he may think himself, trust to his own judgment. So many artful and indeed barbarous tricks are played by horse-dealers to give an apparent age to a colt, and thereby enhance its value, and after maturity to give the teeth that appearance which they would have when the animal had but just attained to its prime of vigour, that even good practical men are often deceived.

The general management of the horse is a matter of serious consideration. The treatment of the foal, the best time for weaning (at five or six months old), the breaking in of the colt, and the proper method to be pursued (on the principle of kindness, not of tyranny or brutal usage) according to the breed and destination of the animal; the training of the racer, the hunter, the roadster, the coach-horse; the amount of labour to be exacted from the working horse in the waggon, the cart, the plough; the diet required under every different phase of labour, and at different seasons of the year; the kind of water (soft, if possible) to be given, and the quantity daily under different circumstances; all these are most important matters to be attended to.

Again, with respect to the anatomical structure of the foot; the qualities of the hoof; the nature and use of the frog; the bearing of the pastern bones on the coffin bone, with their ligaments, tendons, nerves, and bloodvessels; and the inference to be drawn, on physiological principles, as to the proper method of shoeing the hoof, according to the destined work

of the animal and the nature of the ground upon which it has to work; these form additional points of great importance to which the veterinarian has to devote deep attention.

What is the proper *conformation of the Horse*?

This varies essentially with the breed and destination of the animal. Nevertheless there are some points which are valuable in horses of every description. The head should not be disproportionately large, and should be well set on; *i.e.*, the lower jaw-bones should be sufficiently far apart to enable the head to form that angle with the neck which gives free motion and a graceful carriage to it, and prevents its bearing too heavy on the hand. The eye should be large and a little prominent, and the eyelid fine and thin. The ear should be small and erect, and quick in motion. The lop-ear indicates dulness or stubbornness; and when it is habitually laid too far back upon the neck, there is too frequently a disposition to mischief. The nostril in every breed should be somewhat expanded: it can hardly be too much so in the racer, the hunter, the roadster, and the coach-horse, for this animal breathes only through the nostril, and it would be dangerously distressed, when much speed is required of him, if the nostril could not dilate to admit and to return the air. The neck should be long rather than short. It then enables the animal to graze with more ease, and to throw his weight more forward whether he is in harness or galloping at the top of his speed. It should be muscular at its base, and gradually become fine as it approaches the head. The withers should be somewhat high in every horse, except perhaps that of heavy draught, and it does not harm him, for there is larger surface for the attachment of the muscles of the back, and they act at greater mechanical advantage. A slanting direction of the shoulder gives also much mechanical advantage, as well as an easy and pleasant action, and a greater degree of safety. It must not, however, exist in any considerable degree in the horse of draught, and particularly of heavy draught. The chest must be capacious, for it contains the heart and the lungs, the organs on which the speed and endurance of the horse depend. Capacity of chest is indispensable in every horse, but the form of the chest admits of variation. In the waggon-horse the circular chest may be admitted, because he seldom goes at any great speed, and there is comparatively little variation in the quantity of air required; but in other horses the variation is often fearful. The quantity of air expended in a gallop is many times that required in hard work. Here we must have depth of chest, not only as giving more room for the insertion of the muscles, on the action of which the expansion of the chest depends, but a conformation of the chest which admits of that expansion. That which is somewhat straight may be easily bent into a circle when greater capacity is required; that which is already circular admits of no expansion. A few words more contain almost all that is necessary to be added on the conformation of the horse:—‘The loins should be broad, the quarters long, the thighs muscular, and the hocks well bent and well under the horse.’

(See Plates ‘Horse,’ 1 and 2, for illustrations of the bony skeleton and muscular system of the horse.)

Diseases of Horses.—In the medical and surgical treatment of the horse a knowledge of the anatomy

and physiology of the animal is absolutely essential, and forms a basis for an accurate acquaintance with the numerous diseases which befall the horse, their symptoms, prognosis, and mode of treatment; the properties of the medicines, vegetable or mineral, employed, the effects of chemical combinations, and the various doses from which certain effects result. Wounds, fractures, dislocations, ulcers, and a whole class of what are called surgical diseases requiring manual as well as medical treatment, demand a union of the surgeon and physician in the same practitioner. Do not then dabble in physic or surgery, but as there are cases in which common sense will guide you, namely, those in which promptness alone can save, act boldly; the horse will die if you do not, and can but die if you fail. It is in cases of sudden congestion of the brain, threatening apoplexy, that this promptitude is especially needed. Suppose that you are driving or riding a high-fed horse, one perhaps that has been pampered and kept for some time out of work; suddenly he stops, reels, staggers, and falls, and then plunges violently and desperately. What is to be done? Bleed instantly—if possible before the horse falls. If you have no lancet or fleam, a sharp penknife will do. Few, however, could obey our injunction. Bleeding can only be learned practically, and we would therefore recommend every traveller and every man who keeps horses either for luxury or for necessity, to learn the art of bleeding, and to have a lancet ever in readiness about him.

Horses were formerly liable to different rates of excise duty according to height, but in 1869 all distinctions were abolished, and a licence of 10s. 6d. per annum is now required to keep any kind of horse except those used solely for agricultural purposes.

In the year 1867 the number of horses imported into the United Kingdom was 1468, of the value of 33,710*l*. Of this number 291 came from France, 202 from Holland, and 503 from Iceland. In the same year 4136 horses, value 177,651*l*., were exported, chiefly to Hamburg, Belgium, and France.

HORSE-CHESTNUT. [*Æsculus*.]

HORSE-FLY, more properly called *Forest Fly*, is an insect of the order *Diptera*. It receives one name from its frequent occurrence in forests, and the other from its power of teasing horses. It is about four lines long, brown colour, with two wings. It has a remarkable tough skin, which renders it hard to be killed. It lives by sucking the blood of quadrupeds, chiefly horses, but also dogs, oxen, sheep, &c.

HORSE-GUARDS, a public military establishment, situated in Whitehall Place, Westminster, to which all official communications relative to the British army are transmitted. Here are the offices of the commander-in-chief, quartermaster-general, adjutant-general, &c., and here the commander-in-chief receives all applications, either personal or otherwise, relating to the army. Much of the business formerly transacted by this department is now administered by the secretary-at-war.

HORSE-GUARDS, ROYAL, is the third heavy cavalry regiment of the household brigade. It has always been a fine corps of heavy cavalry, and has served in numerous important campaigns. The uniform is a steel helmet, with plume, a steel cuirass over a blue coat, leather breeches and top-boots. The horses are black. The regiment consists of

eight troops, the total cost of which for the year 1869-70 was 24,066*l*., distributed amongst 436 officers and privates. The colonel has 1800*l*. a year; the pay of officers varies from 8*s*. to 29*s*. a day; non-commissioned officers, from 2*s*. to 4*s*.; and 335 privates, 2*s*. 0½*d*., and additional allowances.

HORSE-POWER. A term used in mechanical engineering to express the unity of comparison of the power of steam, or water-power machines, which is based upon the assumption that a horse is able on the average to perform a certain definite quantity of work within a given time. Engineers differ in their estimates of the value of an average horse-power, some reckoning it to be equal to 27,500, some to 29,000, and others to 33,000 lbs. raised one foot high per minute. The latter estimate was the one adopted by Watt, and it is also the one most generally followed both by English and foreign engineers. In calculating the power of a steam engine in terms of this unit, the general rule is to multiply together the pressure in pounds on a square inch of the piston, the area of the piston in inches, the length of the stroke in feet, and the number of strokes per minute, the result divided by 33,000 will give the horse-power; but it is necessary to deduct about one-tenth of the whole, as an allowance for friction.

HORSE-RADISH. [*Cochlearia*.]

HORSE-SHOEING. Although persons practically acquainted with the matter had long been aware that the general method of shoeing horses was the source of many evils, no real improvement was made simple enough to be carried into general effect until a very recent period. The objection to the old method was, that by rasping and cutting the foot was made to fit the shoe, and not the shoe the foot, and the consequence was that the horse could never assume its natural position. Its hind shoes were generally furnished with large heel calks, which elevated the heels an inch or more, and placed the bearing upon a tripod, formed by these calks and by the point of the toe. The frog, intended by nature to be an elastic organ, and to be the medium through which the foot feels the ground, was so lifted up that it could never exercise its functions. It became hard, dry, and useless, and was pared away by the farrier at each renewal of the shoes. On a declivity, or when checked, the horses slipped and staggered, and when at rest their bent knees and quivering limbs testified to the pain and weariness produced by the unnatural attitudes in which they were forced to stand, which was exactly like a man with tight boots.

In 1860 Mr. Goodenough, an American, invented and patented the shoe we are about to describe, and has succeeded, we think, in securing all necessary protection to the hoof, and in removing, or reducing to a *minimum*, the bad effects of earlier methods. The principle laid down by Mr. Goodenough is that the shoe should resemble, and preserve as far as possible, the natural shape of the hoof of which it is a continuation. The unshod horse has the under surface of his foot on a generally level plane, the frog and the whole margin of the hoof in contact with the ground, and the surface of the sole, between the frog and the margin, somewhat raised by its own concavity. The Goodenough shoe is made precisely to follow the outline of the hoof for which it is intended, and to reach exactly to the bars, never

projecting at all beyond the heel. Its upper surface is perfectly plane and true; its under surface is generally concave from the outer to the inner margin, the outer margin having, however, a narrow flat bearing upon the ground, and this bearing is interrupted by portions of the margin being cut away, so as to leave a central toe calk, and two smaller calks on either side. The elevation of these calks is inconsiderable, and their general level is the same, so that they may be compared to a series of short claws on the under surface of the shoe. In the notches, or spaces between the calks, the nail-holes are bored and counter-sunk, so that the nail-heads are completely buried in the shoe. For frost, shoes are made in which the calks have no flat bearing, but are brought up to a feather edge. The inner margin of the shoe is thin, so that its outline passes insensibly into that of the sole, and presents no projections by which stones or snow can be retained. The method of preparing the foot and of applying the shoe is as follows:—

In the first place, a shoe which precisely fits the outline of the hoof is selected from the stock. If a proper fit cannot be found, any slight alteration is made by a few blows on the cold iron, or, if heating be necessary, the shoe is made cold again before it is applied, and care is taken that it remains perfectly level and true. The farrier then prepares the hoof by cutting or rasping away the surface of that portion of the crust on which the iron will rest, leaving the centre of the sole and the frog and bars untouched. Having given what he judges to be a true level to this marginal seating for the shoe, the shoe is applied cold, and the hoof is rasped again and again until horn and iron come into perfect contact in every part. As a guide to the use of the rasp, the surface of the shoe is ruddled, so that any portions of horn not touched by it remain uncoloured. The adjustment being correct, the shoe is nailed on in the ordinary way.

When the shoes are put on for the first time it will often happen that the frog, dwarfed and deformed by previous ill-treatment, does not reach the ground at once, and for some hours, or even for a day or two, the horse may experience the same kind of inconvenience that would be felt by a man who was taken out of very high-heeled boots, to which he was accustomed, and made to walk on level soles. But a very short time restores the muscles of the leg to their natural equilibrium, and relieves the latter discomfort, while, after a few shoeings, the frog reaches the ground fairly and fully, forming an elastic wedge which gives the horse a conscious and safe foothold upon every surface. The sole also grows somewhat within the circle of the shoe and forms a shoulder by which the firmness and security of the latter are greatly increased, so that fewer and smaller nails are required. At first, too, it is necessary to have a considerable thickness of iron, in order to supply the place of the horn usually removed by the excessive cutting of the ordinary farrier; but when the hoof has grown to its natural proportions, smaller and lighter shoes are sufficient.

Mr. Goodenough's system was only introduced into this country in 1868. It was at first tried in England on 200 horses of the London General Omnibus Company. Two months afterwards some of

these horses and some shod in the old method, with high-heel calks, were brought together for inspection, and the improvement was so great that the new plan was at once adopted, and is rapidly becoming general.

It is manifest that a shoe with a perfectly true and level surface, and of a regular pattern, can only be made economically by machinery. Machines have been designed, and a plant consisting of five parts now turns out 18,000 pairs of shoes in a week. The first machine cuts prepared bars of iron into lengths; the second punches the nail-holes at the proper degree of obliquity, so that the nails cannot be driven into any sensitive part of the foot; the third splits the lengths so as to separate each into the two shoes that it is intended to form. The separate portions are then heated, bent round a kind of mould to the proper shape, and, lastly, pressed to the required level. The size of the shoe is determined by the length of the bar, the shape by that of the mould around which it is bent.

HORSE-TAIL. [EQUSETUM.]

HORSES, TAMING OF. The subjugation of vicious or intractable horses, by which they can be rendered docile and obedient to the requirements of man, is a matter of serious consideration; and various methods have been pursued to effect so desirable an object. We have already stated that the general management of the horse must not be by 'tyranny or brutal usage, but by kindness;' and Youatt, in his valuable treatise on the subject, says, that 'it is surprising how soon, under a system of kind management, the animal which has been accustomed to go where he pleased, and to do as he thought fit, may be taught to yield up his will to another, and to obey with alacrity his master's bidding. If there is a kind-hearted and faithful servant about the premises who will undertake this task, the breeder is fortunate; for without this, he is often compelled to resign his colt to the tender mercies of a colt-breaker—a man who seldom has any conception of obtaining his object by the moral influence which kindness would give him over the youngster, but who has too frequent recourse to violence, and that of the most outrageous kind, until the colt becomes a dull, dispirited, useful, but desponding and ill-treated slave through life, or cherishing a deep feeling of wrong and a spirit of revenge, becomes determinedly vicious and dangerous.'

Some years since much interest was felt in England on the subject of horse taming in consequence of the success of a Mr. Rarey from America, whose method of curing a wild or kicking horse is to tie up one of his fore feet, so that his hoof will appear bottom upwards, and nearly touching his body. There is no process in the world, he says, equal to it for breaking a kicking horse. He will sometimes become very restive, and try every possible way to get down the leg; but on finding he cannot do that, he will soon become settled down; and when you perceive that he is subdued, advance gently towards him, let down his foot, rub his leg with your hand, caress him, and let him rest a little; then put the leg up again; and by repeating this process several times, the horse will soon learn to walk some little distance on three legs. Let him be the most vicious horse in the world, he cannot kick in this position. When he has been taught to understand that you do

not intend to hurt him, you can let down the leg, and drive along gently without further fear or trouble.

HORSHAM. [*SUSSEX.*]

HORSLEY, SAMUEL (born 1733, died 1806), a distinguished prelate of the English church, successively bishop of St. David's, Rochester, and St. Asaph. He was the son of John Horsley, who held two rectories. The bishop was educated at Westminster School, from whence he passed to Trinity Hall, Cambridge, and his father resigned to him the rectory of Newington in Surrey.

In 1767 he was elected a Fellow of the Royal Society, to which body he became the secretary in 1773. In 1776 he projected a complete and uniform edition of the philosophical works of Sir Isaac Newton. This design was not accomplished till 1784. In 1781 he had been appointed archdeacon of St. Albans; and it was a little before that date that he first appeared in the field of theological controversy. The person against whom he chiefly directed his attack was Dr. Joseph Priestley, a minister among the Presbyterian dissenters, who in a series of publications defended the doctrines of philosophical necessity, materialism, and unitarianism. Dr. Horsley began his attack in 1778 on the question of Man's Free Agency; it was continued in a Charge delivered in 1783 to the clergy of his archdeaconry.

The tide of preferment now began to flow in upon him. Thurlow, who was then chancellor, presented him with a prebendal stall in the church of Gloucester. In 1788 he was made Bishop of St. David's. In 1793 he was translated to Rochester, and in 1802 to St. Asaph. Bishop Horsley's 'Sermons' have been published in 1 vol. 8vo. and in 2 vols. 8vo., his 'Charges' in 1 vol. 8vo., his 'Biblical Criticism' in 4 vols. 8vo., and his 'Theological Works' in 8 vols. 8vo.

HORTA. [*FAYAL.*]

HORTEN, a town of Norway, 32 miles south of Christiana, on the gulf of that name. It is the chief military port of the kingdom, and station of the fleet, and has an arsenal and extensive building yards.—(*Johnston's Gazetteer.*)

HORTENSIVS, QUINTUS, born B.C. 114, of an equestrian Roman family, had attained a great reputation as an orator when Cicero made his appearance in the Forum. From that time Cicero and Hortensius were considered as professional rivals, but they lived on friendly terms. At the beginning of his book 'De Claris Oratoribus,' Cicero pays an eloquent tribute of praise to the memory of Hortensius, who was then lately dead. Hortensius was successively quaestor, ædile, prætor, and lastly consul, with Q. Cæcilius Metellus Creticus, B.C. 69. He acquired great wealth, which he spent liberally, and yet bequeathed an ample inheritance to his children. Hortensius died B.C. 50. Cicero ('Brutus,' c. 92, 95) has given his opinion of the character of Hortensius as an orator.

HORTICULTURE. [*GARDEN.*]

HORTUS SICCUS. Literally, 'a dry garden;' an appellation given to a collection of specimens of plants carefully dried and preserved.

HOSEA, one of the twelve minor Hebrew prophets. We possess no particulars respecting the place of his birth or his history; but we learn from the inscription of the book that he was the son of Beeri, and that he lived 'in the days of Uzziah, Jotham, Ahaz

and Hezekiah, kings of Judah, and in the days of Jeroboam the son of Joash, king of Israel.' It is therefore probable that the prophecies of Hosea extended over a period of about sixty years (B.C. 784–724), and that he was contemporary with Isaiah, Micah, and Amos.

The canonical authority of the prophecies of Hosea has never been disputed. They are frequently quoted in the New Testament; compare Hos. vi. 6 with Matt. ix. 13, xii. 7; Hos. x. 8 with Luke xxiii. 30; Hos. xi. 1 with Matt. ii. 15; Hos. i. 10, ii. 23 with Rom. ix. 25, 26, and 1 Peter ii. 10; Hos. xiv. 2 with Heb. xiii. 15.

HOSHUNGABAD, a district or subdivision of British India, known as the Saugor and Nerbudda territory, in the north-west provinces. The area is 1916 square miles, and the population numbers 242,641. The district is very fertile, and has coal of superior quality, but the distance from the sea-coast is a great drawback to its being worked.—*Hoshungabad*, the chief town, is situated on the left bank of the Nerbudda, 114 S.W. Saugor, in lat. 22° 44' N., and long. 77° 44' E.—(*Johnston's Dictionary of Geography.*)

HOSIERY. The principal seat of the hosiery manufacture in England is in the three midland counties of Leicester, Nottingham, and Derby. In the first of these, woollen hosiery forms the principal branch of the manufacture, while in Nottinghamshire the material chiefly used is cotton, and in Derbyshire silk goods are mostly made.

The stocking-frame, by means of which this manufacture is carried on, is, next to the common warp and weft loom, the oldest machine in existence applicable to textile fabrics. It was invented about the close of the 16th century by the Rev. William Lee, of St. John's College, Cambridge, but a considerable time elapsed before the produce of this frame took the place of the trunk-hose then worn by all who could afford such an article of dress. For this reason Mr. Lee settled at Rouen, in Normandy, where his manufacture was carried on under the patronage of Henri IV.; but the assassination of the king and the political troubles brought on by that event caused the abandonment of Mr. Lee's establishment, and that gentleman shortly after died in a state of poverty at Paris.

From the period of its first invention the stocking-frame received no considerable improvement until very recently. Frames, however, with a rotatory action, and worked by steam power, have been brought into use at Nottingham, and will doubtless ere long entirely supersede the old reciprocating engine, as the economy effected in the process of manufacture is very great. The working of a rotatory machine impelled by steam power, in which twelve stockings are made at the same time, only requires the attendance of a man and a boy; whereas, in the old frame, but one stocking can be made at once by a single workman. The cotton branch of the hosiery manufacture differs from the woollen and silk in the relative proportions of the cost of labour as compared with that of the material. In cotton hosiery the cost of labour constitutes from two-thirds to five-sixths the value of the goods; while in woollen the labour does not exceed two-fifths of the value; and in silk goods the proportion is still smaller.

It is difficult to describe the processes of the hosiery manufacture without the use of many woodcuts, and even then the routine is not well understood without seeing the machines really at work.

In its more general application the term hosiery includes gloves, waistcoat pieces, pantaloons, drawers, braces, webs, comforters, caps, jackets, leggings, and various other articles made nearly in the same way as stockings, and of the same material. The processes for worsted, cotton, and silk are nearly analogous; those for silk, however, requiring the greatest care. Ireland has produced some of the finest specimens of hosiery in the world—a dozen pairs of ladies' full-size stockings weighing only nine ounces. The exports of cotton hosiery from the United Kingdom, in 1866, comprised 613,425 dozen pairs of stockings and socks, value 240,534*l.*; 29,761 dozen pairs of gloves, value 8962*l.*; 53,040 dozen pairs of shirts and drawers, valued at 57,582*l.*; and hosiery of other kinds valued at 146,759*l.* Of silk hosiery of all kinds exported, the value was estimated at 23,897*l.*; and of woollen—including 189,473 dozen pairs of stockings and socks, 33,297 dozen shirts, drawers, &c.—307,782*l.* The countries which received the largest quantities of each description were Australia, India, and the United States.

The imports of hosiery in the same year—both cotton and woollen—were valued at 88,982*l.*, nearly the whole of which came from Hamburg.

The principal seat of the cotton hosiery manufacture abroad is at Chemnitz, in Saxony, where, owing to the low rate of wages, goods are made, with yarns imported from Lancashire, at prices which have rendered them formidable competitors to English goods in many foreign markets, especially those of the United States.

HOSPICES are institutions founded and generally supported by monks, as resting-places for travellers on the Alpine passes. The oldest of these is on Great St. Bernard, and others are found on St. Gothard, Mont Cenis, the Simplon, and the Little St. Bernard.

HOSPITAL (from the French *hôpital*, and of which the word *spital* is a contracted form), a place endowed for the reception of the sick or support of infirm persons. Hospitals intended merely for the relief of poor and indigent persons in England are called ALMS-HOUSES. At an earlier date hospital signified a place of shelter and entertainment for travellers upon the road, more especially for pilgrims. Many of the charitable endowments in England are called hospitals. They are generally incorporated bodies, and often have schools attached to them, in which the children are sometimes boarded as well as educated. The name is, however, now more generally restricted to places for the reception of sick or wounded persons, and such hospitals are very numerous in the United Kingdom. In London the chief exceptions are the Foundling Hospital, for the reception of illegitimate children abandoned by their fathers; Christ's Hospital, an educational establishment; St. Luke's and Bethlehem Hospitals, for lunatics; and Chelsea and Greenwich Hospitals, for the reception of soldiers and seamen. Medical and surgical hospitals are established in almost every large town in the kingdom, and in London they are numerous. The oldest, and perhaps even yet the

most important, is St. Bartholomew's, founded in 1547; St. Thomas', changed from a religious establishment to a medical hospital in 1551; and Guy's, opened for the reception of patients in 1725. These are supported by endowments, and are very wealthy; but most other hospitals in London, as well as nearly all in the country, depend mainly upon voluntary contributions for their support. As to the management of their revenues and general superintendence, hospitals are on the same legal footing as other charities.

In addition to their value as a means of relief in disease, hospitals are naturally the very best schools of medicine, and nothing is so certain to secure a physician or surgeon a good private practice, as the knowledge that he has considerable hospital experience. Most hospitals are open by night as well as day to receive pressing cases, and there are always a surgeon and assistants in attendance. Visiting physicians, each of whom generally superintends special classes of complaints, also attend daily.

In the general report of the last census of the United Kingdom, the commissioners divide the hospitals for the sick in England into three classes:—General Hospitals, in which are received as in-patients or treated as out-patients, according to the urgency and severity of the cases, persons suffering from diseases (with certain exceptions), accidents, injuries, and deformities; Special Hospitals, which receive patients suffering from one class of diseases, as fever, small-pox, cancer, or consumption; and Class Hospitals, which receive only one description of persons, as soldiers, sailors, women, children, &c. In some parts of England hospitals are called infirmaries. Dispensaries are medical charities for out-patients only, who are often visited at their houses.

Exclusive of the patients in the military and naval hospitals, and in the sick wards of workhouses, prisons, &c., there were in hospitals in England and Wales, on the day of the last census, 10,414 patients, of whom 5970 were males, and 4444 females. In 1851 the number did not exceed 8617, and the increase of 1797 persons enumerated in these establishments may be ascribed to the additional accommodation for the sick afforded through the erection of new hospitals, and the enlargement of those already established. The above figures give the ratios of 1 in 1927 of the population in civil hospitals in 1861, and 1 in 2080 in 1851.

By far the highest ratio of the sick in hospitals is found in London, where 17.0 males, and 12.6 females in every 10,000 of each sex were enumerated in these institutions, which contained 4102 out of the 10,414 patients. Many of the patients come from the country, attracted by the great reputation of the medical staff of the metropolitan hospitals, or are sent up by country practitioners.

Although the primary design of these institutions is to afford a refuge to persons who are unable to pay for private medical or surgical aid, there is good reason for believing that their benefits are not mainly conferred on those for whose special relief they were established, but frequently on workmen in receipt of high wages, and their families, who are scarcely to be regarded as proper objects of such charities. That the class of artisans and other working-men in our towns are, when employed, well able to set aside a

small sum from their earnings to join a sick club or other provident society to provide for the evil days of sickness cannot be questioned; but it is said by competent judges that the indiscriminate manner in which gratuitous medical relief is afforded at the hospitals, more especially in London, only tends to encourage in the workman habits of improvidence.

Of late years the various matters connected with hospital administration have received the most careful attention of the medical profession and others well qualified by long experience to speak with authority on such subjects. The labours of Miss Nightingale may be said to have created a new era in hospital management, and the reforms advocated by that lady are now being carried out in some of the most important of these institutions. (See *Notes on Hospitals*, a third edition of which has been published).

Hospitals are found in most European countries, the *Maison Dieu* in Paris being the oldest, and one of the largest and best conducted, in the world. In many of the continental institutions the Sisters of Mercy render invaluable assistance in nursing, dispensing medicine, and in cooking, &c.

HOSPITALS, MILITARY, are of three kinds, viz., the Regimental, under the medical officers of the regiment; the Divisional, presided over by staff medical officers, for the benefit of all the corps in the division; and the General, for the use of the whole force. Soldiers while in hospital are subjected to a stoppage of 9*d.* a day from their pay if abroad, and 10*d.* if at home. The estimated amount of stoppages for 1867-68 was 79,839*l.*; and the total cost for medical establishments, services, and supplies for the same year, 275,589*l.* The medical staff comprises 331 persons, at a cost of 114,066*l.* per annum. The general hospitals at Netley and Woolwich figure for 4884*l.*, medicines cost 29,731*l.*, and the expenses of the purveying department were estimated at 129,152*l.*

HOSPITALS, NAVAL, are similar establishments for the cure of sick and wounded seamen. In England there are naval hospitals at Haslar, Plymouth, Haulbowline, and a lunatic asylum at Yarmouth. Abroad the English navy possesses hospitals at Malta, Bermuda, Jamaica, Cape of Good Hope, and Hong Kong.

HOSPITALLERS. [MALTA, KNIGHTS OF.]

HOSPODAR is the title of the persons formerly sent by the Turkish sultan to govern Wallachia and Moldavia, the two provinces north of the Danube. These governors for more than a century were taken from the principal Greek families of the Fanar [FANARIOTES], such as Mavrocordato, Soutzo, Calimachi, Ypsilanti, &c. They assumed the title of princes, and were addressed as 'most serene highness.' They held in their respective capitals, Bucharest and Jassy, a numerous court, consisting chiefly of Fanariote Greeks, and were, in fact, almost absolute sovereigns during the time of their administration. This, however, might be shortened at the pleasure of the Porte, who often recalled them, and put them to death. At the time of the Greek revolution in 1821, the hospodar of Moldavia escaped into the Russian territory, and his relative the hospodar or prince of Wallachia was poisoned. Afterwards the government of the two principalities was vested in one hospodar, elected separately by each; but in

1861 the provinces were united under the name of Roumania, and the present governor, Colonel John Alexander Couza, who was elected hospodar of Moldavia, January 17, 1859, and of Wallachia, February 5, 1859, is now styled John I., prince of Roumania.

HOST (*hostia*, 'a victim') is the name given in the Roman Catholic church to the consecrated bread used in the sacrament of the eucharist. It is made of fine flour, unleavened, in the form of a wafer, and usually has some device or inscription on it, having reference to the sacrifice. The Greek church and Protestants generally use leavened bread for the same purpose.

HOSTAGE, one given in pledge for security of performance of conditions. In warfare it is usual, when a town surrenders, for besiegers and besieged to give into each other's hands several officers as pledges that both sides will duly carry out the terms agreed upon. Should either party fail, the other has the right to put to death or punish in any way the hostages, though it is seldom that any severer measures than ordinary imprisonment are carried out. When the terms of treaty are fulfilled, the hostages are exchanged.

HOT-BED, a name given by gardeners to a heap of fresh stable litter in a state of fermentation, upon which a glazed box is placed for the cultivation of certain plants requiring heat and moisture in greater quantity than those agents exist in the external air. Formerly hot-beds were more exclusively used for various purposes in horticulture than they now are. This is owing to the perfection to which other means of producing and applying artificial heat have now attained; but still, for the growth of cucumbers and melons, raising seeds of tender annuals, and of other plants, either culinary or ornamental, hot-beds continue to be advantageously employed, as they likewise are for the striking of cuttings.

Hot-beds may be formed of various substances, such as unrotten dung, tan, leaves, or a mixture of these with moist litter; in short, any substance capable of producing and retaining fermentation, and which will admit of being built up so as to support a frame with sashes. The substance, however, that is most generally used is fresh stable-dung. The preparation which it requires consists in its being thrown in a heap, and also watered, if it contains much dry litter; and, as fermentation proceeds, it should be turned two or three times, and mixed thoroughly in the process.

The situation in which hot-beds ought to be formed should be dry, open to the south, and well sheltered in every other direction, either by walls backed by high and close-growing trees, or by very close and lofty hedges. Such extensive shelter, though desirable, cannot always be obtained; but some mode should be employed to break the force of sweeping winds. The basis on which the bed is to be formed should be marked out from four to six inches each way beyond the dimensions of the frame intended to be placed upon it; and if faggots or a layer of brushwood be laid as a foundation, it will admit heat completely under in case a diminution of heat in the bed requires the application of a *lining*, which is a quantity of fresh materials added to the outside. The bed is then built of successive layers of the prepared materials, each layer being beaten tolerably

compact with the fork as it is laid on, to the height of four feet in front, and four feet nine inches at the back: the sides and ends should be quite perpendicular. The top layer should be as free from litter as possible. When thus finished, the frame and lights are placed upon it, and as soon as the violence of the fermentation has diminished, mould is put in; and when the latter has acquired a proper temperature the plants are introduced. Instead of mould, rotten tan, or leaf mould, or sand, is spread over the surface of the bed, when pots containing seeds or cuttings are to be plunged.

As soon as the heat of the bed begins to decline, a *lining* of fresh materials must be applied. This, however, may be composed of substances that have not undergone any previous fermentation, and may consist of fresh stable-dung, merely shaken up as it is placed against the sides of the bed, or of grass mowings, or of leaves, or of a mixture of such substances. It sometimes happens that, notwithstanding every precaution as to its formation, a hot-bed will become too hot for plants or seeds that may have been placed above it. In this case the only remedy is to remove the plants until the bed has been re-made, with the addition of some materials, the fermentation of which is slower and less violent. Gardeners sometimes attempt to avoid the trouble of doing this by piercing the sides of the hot-bed with holes for the egress of heat; but this is seldom an effectual remedy for the evil.

HOT BLAST. In ironworks, a current of heated air injected into a furnace by means of a blowing-engine. It has been found that by employing heated air instead of cold air in blowing furnaces, a great saving is effected in fuel, and a great increase in the quantity of iron produced. The temperature to which the air is raised before it enters the furnace is about 600° Fahr. Furnaces constructed on this principle are called hot-blast furnaces, of which the invention is due to Mr. Neilson, of Glasgow.

HOT-HOUSE, in Horticulture, is a structure in which exotic plants are cultivated under circumstances approximating as closely as possible to those under which they naturally exist; or it is used for accelerating the production of flowers and fruits of either indigenous or exotic plants. Hot-houses appropriated to the latter purposes are very frequently termed *forcing-houses*.

The principles by which the construction of hot-houses must be governed have reference to the three great agents in vegetation—*heat, moisture, and light*.

With regard to *heat*, the building must provide for a sufficient amount to raise the internal temperature of the house, from that of the lowest degree of external air that occurs in this climate, to that of the highest which prevails for any length of time in the countries of which the plants intended to be introduced are natives.

Moisture is of very great importance, and a due proportion of it is frequently more difficult to maintain in the atmosphere of the house than heat, and more so by some modes of heating than by others. It therefore follows that, as all applications of fire-heat have a tendency to produce too great a degree of dryness, that mode is the best for the growth of plants which allows the greatest quantity of vapour to remain uncondensed in the atmosphere of the house.

Some tribes of exotic plants, natives of the torrid zone, are adapted for existing under a very dry atmosphere. Instead of developing a thin expanded foliage, they form thick succulent masses, which no degree of atmospheric dryness seems to injure. Plants of such a nature necessarily require a *dry stove*. In tropical countries the air is saturated with moisture during the night, or at least it is but very rarely otherwise in the open air. But if due precautions be not taken, and temperature only is attended to, without regard to moisture, a degree of dryness will prevail at night in hot-houses, which is double that of the tropic during the day. Artificial heat having therefore this excessive desiccating tendency, the necessity becomes obvious of adopting such modes of construction and heating as will afford the best means not only of supplying but of maintaining moisture; for vapour may be raised till the air of the house is at the point of saturation, and yet causes may operate so as to occasion a speedy condensation and a consequent dryness.

Light cannot be admitted too freely into hot-houses. This will appear evident from the circumstance of the most transparent medium that can be used reflecting a great proportion of the sun's rays when they impinge obliquely on its surface.

Although the necessity of admitting as much light as possible is now generally acknowledged, and although in cloudy weather great advantage will be derived from a roof rendered as transparent as possible, yet the generality of tropical plants do not thrive in bright sunny weather when placed near the glass of a hot-house in this climate; and the necessity of a screen of netting will appear obvious from the effects of solar radiation observed in the tropics as compared with, what is rather surprising, the still greater energy of the same in this country.

With regard to the means of supplying artificial heat, the old system of using brick flues is now rapidly being superseded by that of hot water. Hot-water pipes, once fitted up, require no repairs for many years; whereas the brick flues must be frequently broken up in order to clear out the soot. By hot water the distribution of heat can also be better regulated, and the uniformity of temperature better maintained, than by any other known means. The methods of heating by hot water are various, and steam, forced through pipes, has also been extensively used as a heating agent.

With regard to a supply of moisture, the hot-water system, in which the pipes are level, or nearly so, presents several advantages over other methods of heating.

Various modes of ventilation are in use. It should be so contrived as to be sufficiently effective in preventing excess of heat; but at the same time it should be perfectly at command, so that it may be employed when requisite in the most limited degree. No method should be finally adopted until it is put to the test by trying whether, under any agitation of the external air, a candle will burn steadily inside if placed near the apertures by which the air is admitted.

In all forcing-houses tanks should be placed for supplying water of a temperature more suitable to the nature of the vegetation than that from a pump out of doors. Nothing can be more injurious than

cold water applied to the roots and tops of tropical plants, or others in a forcing state, under a high temperature. The rain and dews which supply the plants of warm climates cannot be much below the mean temperature of the climate; and if only equal to the minimum, still it would be between 20° and 30° above that of spring-water in Britain.

Hot-houses may be classed under four different heads, namely, the *Dry Stove*, the *Damp Stove*, the *Bark Stove*, and the *Forcing-house*.

The *Dry Stove*, as the name implies, is used for the cultivation of plants which do not require much water: such as the different species of Cacti, some Euphorbias, and other succulents of like habits. The temperature of such a house during the winter months should never exceed 55° Fahr. No water should ever be given at that period, unless the plant shows signs of suffering from want of it. In spring, or early in summer, most of the plants will show an inclination for growth, and then they may be watered about twice a week. During summer fires may be discontinued, and plenty of air given in fine weather.

The *Damp Stove* requires treatment of an opposite description. Instead of being kept dry like the last, its atmosphere should be always excessively humid, except in the winter season, when the sky is generally cloudy, and the sun's rays weak. Various methods are adopted to keep the atmosphere in this saturated state. When the house is heated with common smoke flues, the most simple way is to throw water frequently upon them, and also upon the passages and other places, from which it will evaporate, and surround the plants with a moist atmosphere. It is a very bad plan, but one too often practised, to water at random, giving all the plants almost an equal share, regardless of their different capacities. Some will require a very abundant and constant supply, whilst others will almost live on the atmospheric moisture which surrounds them. Another thing to be attended to in the treatment of this stove is the placing of the plants. They must be regularly looked over, tied up, and kept clear of each other; elevating some, depressing others, and giving the whole, not only enough of room, but also a natural appearance. The temperature should be, in winter, 55° or 60° Fahr.; in spring it may be gradually raised to 70°; and during fine weather, in the middle of summer, fires may be discontinued for about three months; but the thermometer should never be allowed to sink lower than 60°.

The *Bark Stove*, when it is of large dimensions, consists of a pit in the middle of the house, surrounded by a brick wall, leaving as much room round the sides as will form a passage to walk in. The pit is filled with bark (commonly called tan, from its having been used previously by the tanners), and, after being allowed to sink a little and ferment, the pots containing the plants are plunged more or less deep as prudence may suggest. A bark bed is found useful in the cultivation of all those kinds of plants which are grown in the damp stove; orchidaceous plants, for example, succeed admirably in this way. The treatment of it, so far as the temperature, watering, and syringing are concerned, is precisely the same as for the damp stove.

What are called *Palm-houses*, *Musa-houses*, *Orchidaceous-houses*, &c., are merely damp stoves of dif-

ferent dimensions, for the cultivation of those different subjects.

The only other hot-house distinct from those already noticed is the forcing-house. [FORCING.]

Hot-house plants are peculiarly liable to the attacks of insects. The most common kinds are the Green-fly, Thrips, Red-spider, Brown-scale, and Mealy-bug. The first of these is easily conquered by fumigating the house with tobacco, or syringing the plants with an infusion of the same substance. The best remedy for the thrips and red-spider is to syringe well, and keep the house very moist and warm, as those insects cannot live in excessive moisture; a little of the flower of sulphur shaken upon the leaves will also destroy them. The brown-scale and mealy-bug are the worst of all that infest plants in hot-houses. Bruised laurel leaves strewn upon the passages and other parts of the house are said to destroy them, but these must be used with great caution, as they may not only kill the insects but the plants themselves. Various other substances are said to destroy them, but, after all, the best and surest remedy is to wash them off. This is perhaps rather difficult where these little intruders are numerous, but after the plants are once clean, it is an easy matter, with a little attention and diligence, to keep them so.

HOT-WALL. Hot-walls, or walls with flues in them, are constructed in cold countries, in order to afford warmth to trees placed against them, so as to counteract the effects of frost in autumn, when the wood and buds are maturing, and in spring, when the blossoms and leaves are unfolding. If hot-walls are used for these purposes only, they are productive of great benefit to the plants which they shelter; but if, as often happens, in addition to this it is attempted by their aid to advance the ripening of fruit in any considerable degree, hot-walls are of very doubtful service.

One furnace is allowed for heating about forty feet of wall, that is, twenty feet on each side of the place where the fire is situated. The flues are led as obliquely, and make as many turns from right to left, as is consistent with their drawing well, so that as much heat as possible may be given to the tree, and as little as possible escape by the chimney. Occasionally, glass frames or screens are placed in front of the tree.

HOTEL, the term applied to an inn or place of temporary accommodation for travellers. It is derived from the French *hostel* or *hostellerie*; but in that country it is not exclusively applied to houses of public accommodation, but is also used to designate the town residence of a great personage, as the word inn, in England, was once applied to the city residences of distinguished individuals. The inns of ancient times were generally only suited for the humbler classes of travellers, and at many refreshment was gratuitously distributed to poor wayfarers. With the introduction of Christianity, the duties of hospitality and the claims of religion for a long period rendered inns unnecessary—more especially when monastic establishments became general. But with the advance of civilization and the consequent increase in the number of travellers, it became desirable to establish places where food and shelter could be procured and paid for as a matter of business.

Hence the origin of the modern inn, which, in England especially, soon attained to a position of respectability and importance. A good idea of many of the old London inns is given in 'The Curiosities of London,' by Mr. Timbs; and descriptions of the English inns of the last century are met with in the writings of Johnson, Goldsmith, Fielding, and Smollett. They have also been celebrated in elegant prose by Washington Irving; and in many of Dickens' works are laments over their departed glories. The great changes effected in travelling by the introduction of railways have resulted in many of the good old-fashioned English inns being converted into, or superseded by, hotels—buildings of a much more pretentious character. In fact, some of the more recently erected—such as the Charing Cross, Grosvenor, London Bridge, and Langham, in London, and the Grand hotel at Brighton—are quite palatial structures, the first mentioned being certainly one of the finest buildings in the metropolis. All of those mentioned were built and are managed by joint-stock companies, and as regards accommodation are at least equal to most of the magnificent continental hotels. One of the chief reasons of the greater expense of living at an English hotel is, that the foreign system of taking meals at a *table d'hôte*, and, of course, thereby materially lessening the general charges, has never become popular in this country—owing, perhaps, to our national reserve and exclusiveness.

In the United States the hotels, or boarding-houses, are by some preferred to private houses as places of residence. They are conducted somewhat on the continental plan, *i.e.*, the meals are supplied in the *table d'hôte* style at a common charge, including everything but wines and spirits, of about 10s. 6d. per day. Many of them are very splendid establishments, and contain from 180 to 800 rooms each.

The law with respect to English hotels and the liability of innkeepers, is laid down in the article INN.

HOTMAN, FRANCOIS, called also by his Latinized name HOTOMANUS, was born at Paris in 1524, of a family originally from Silesia. He studied law in the University of Orléans, and afterwards practised at the bar. About 1547, when he embraced the Reformed religion, his father refused him his support, and Hotman repaired to Switzerland, where he taught humanities in the College of Lausanne. In 1550 he was appointed professor of law at Strasburg. He afterwards became professor of law at Valence, and then at Bourges, from which last place he ran away, after having concealed himself during the massacre of St. Bartholomew, and repaired to Geneva, and then to Basel, where he died in 1590. His works, in three volumes folio, were published in Geneva in 1599.

HOTTENTOTS. [AFRICA; CAPE OF GOOD HOPE.]

HOTTONIA, a genus of plants belonging to the natural order *Primulaceae*. It is a native of Great Britain in ponds and ditches, and is called the Water-violet. The leaves are submerged and crowded; the flowers rising above the water are of a purple and yellow colour. It is a pretty plant, but possesses no useful properties.

HOUBIGANT, CHARLES FRANCOIS, a priest of the Oratory, and an eminent biblical scholar, was born at Paris in 1686. His devotion to study pro-

duced a serious illness, which terminated in total deafness. Being thus incapacitated for public duty, he directed his principal attention to the study of Hebrew, in which he followed the system of Masclef, who was a strenuous opponent of vowel points. In 1732 Houbigant published his 'Racines Hébraïques,' and in 1746 his 'Prolegomena' to a new edition of the Hebrew Bible. His great work, entitled 'Biblia Hebraica cum Notis Criticis et Versione Latina ad Notas Criticas facta,' appeared at Paris in 1753, in four volumes folio. Houbigant died October 31, 1783, in the ninety-seventh year of his age.

HOUBRAKEN, the name of two Dutch artists, father and son:—

Arnold Houbraken, the father, was born of a good family at Dort in 1660, and was the pupil of Samuel van Hoogstraten. He painted history and portraits, and executed many designs for booksellers. He lived chiefly at Amsterdam. Houbraken is best known by his account of the lives of Dutch painters, with portraits engraved by his son, in continuation of Van Mander—'Groote Schouburg der Nederlantsche Konstschilders en Skilderessen,' in three parts, published in 1718, 1719, and 1721. Houbraken died in 1719.

Jacob Houbraken was an admirable engraver. He was born at Dort in 1698. The most beautiful specimens of Houbraken's engravings are some of 'The Heads of Illustrious Persons of Great Britain,' published in London by the Knaptons in 1748. He died in 1780.

HOUGUE. [MANCHE.]

HOUND (German, *Hund*), a term generally applied to dogs of chase, and most strictly to those which follow their prey by the sense of smell. Nevertheless, it is popularly applied to such as hunt down game by sight, as the Scottish Deerhound and the Greyhound, or Gazehound. [BEAGLE; BLOOD-HOUND; GREYHOUND; HARRIER.] Our ancient breeds of hounds have merged into lighter and swifter races. Of these the Foxhound takes the pre-eminence in speed, vigour, and endurance.

HOUNSLow. [MIDDLESEX.]

HOUR, HOUR-CIRCLE, HOUR-LINE. The first word means the twenty-fourth part of a day, by what revolution soever the day may be measured. In angular measure, it signifies the twenty-fourth part of a complete revolution, or 15°. The division of the day into hours is very ancient. It was probably known to the Babylonians and Egyptians, and from them derived by the Greeks and Romans. They, however, only confined their division to the natural day—while the sun was above the horizon—which they divided into twelve parts. Consequently the length of the hour constantly varied, but the system, with the addition of a similar division of the night, continued till about the fourth century, when the present plan was adopted. Except in Italy—where the day is reckoned from sunset to sunset, and the hours counted from one to twenty-four—all European countries commence the day at midnight, and divide it into two parts of twelve hours each. The Chinese hour is twice the length of ours, they having only twelve for both day and night. Astronomers reckon from mid-day to mid-day, counting one to twenty-four.

Any great circle on the sphere which passes

through the two poles is called an hour-circle, because the hour of the day is known when that circle of the kind mentioned is ascertained upon which the sun is for the time being. But the two semicircles into which the poles divide such a circle belong to different hours, and are twelve hours asunder. In fact, it is a *semicircle* which is spoken of under the term *hour-circle*.

The hour-lines of a dial are the lines on which the shadow falls at different hours, and are the intersections of the hour-circles with the plane of the dial. In the times preceding the common use of clocks, the science of dialling was of considerable importance, and many works were written on the subject, in which the forms of such instruments were varied without end, and also the methods of constructing them.

HOUR-GLASS, a glass instrument for measuring intervals of time. It consists of two bulbs of glass, united by a narrow neck, with a hole communicating one with the other. One end is partly filled with fine sand, of sufficient quantity to run through the neck into the other end in a given time—an hour, if it is to be an hour-glass; a minute, if a minute-glass. Hour-glasses were formerly much used in churches.

HOUSE. The degree of comfort exhibited in the arrangement of their houses is one and a very important characteristic of a nation's degree of civilization; and we may mark the progress of this civilization in its successive stages from a rude condition to a high state of perfection by studying the architecture of a people as shown in their ordinary dwellings.

There is a model in the British Museum representing, most probably, a part of an Egyptian house. It appears, to judge from the figures, to be about ten or twelve feet square, and fourteen or fifteen feet high. It is called a granary. In the lower part of this model, which has two stories, there is a court, the angles of the walls of which are raised a little higher in a sweep. The door into the court is low and roughly constructed, the hinges being merely wooden pins let into a socket above and below. The stairs leading to the upper part appear to be formed of a solid beam placed *aslant*, and the steps notched out. The walls are plastered. The roof appears to have been flat. There are three clamped and partly framed square-shaped doors to the mouths of the granaries.

Vitruvius (vi. 10) gives a general description of a Greek house, which differed from the Roman in not having a vestibule and atrium; and the Greek practice of separating the apartments of the females from those of the males led to an entirely different internal arrangement.

The modern Greek house is of a quadrangular form, with a court in the interior; the staircases are placed on the external part of the house, leading to a gallery round the first floor. The entrance is in the centre of the quadrangle; over the entrance is the sitting apartment of the women; a bow-window is placed in this apartment, over the door. In the lower story the cattle are often placed. The women's apartments are separated from the men's, as was the custom among the ancient Greeks. Many Greek houses are exceeding mean and ill-furnished.

The most perfect remains of ancient Roman houses are at Pompeii. Those called the house of Pansa and the house of Sallust are especially remarkable for

their size and grandeur. The Pompeian ruins exhibit the dwellings of both the rich and the poor; the latter are small and meanly finished; the former are in comparison extensive, and often richly decorated with columns, paintings, and mosaics. The principal features of a Roman house are the atrium, the tablinum, and the peristyle. The *atrium* is a kind of central quadrangular hall or court, having in the middle an *impluvium* or tank to catch the rain-water which falls through an opening in the roof. The *tablinum* is a kind of passage, paved with mosaic, which leads from the atrium to the *peristyle*. This peristyle is a second and larger quadrangle, supported by pillars, and having a basin or fountain in the centre. On all sides of these quadrangles are the various domestic apartments.

The walls of Roman houses were decorated with arabesque paintings, which added an agreeable charm to the light and airy apartments of a hot climate.

Three centuries ago English houses were constructed in a very different manner from the houses of the present century. The chief materials were wood and plaster, and a common but peculiar feature was the projecting upper floors. The internal arrangement was adapted to the wants of that day, and the external architecture had often a picturesque appearance. The modern English house, which is most commonly of brick, varies in its arrangement according to the wealth of the occupier, or the skill and taste of the architect. The houses of the middle class, especially in cities, are nearly the same in their chief features.

The floors of English houses are constructed of wood, and boarded; and the roofs, which are pitched, or at an angle, are covered with slates or tiles. The rooms are heated with open grates, with flues over them, the exit for which is above the roof.

The chimney-flue is a very important feature of an English house, as upon its construction depends the comfort of having the apartment free from smoke.

The staircase of an English house is usually constructed of wood, with a protecting baluster, often elegantly formed, on one side.

Every convenience which ingenuity can contrive is now found in the numerous minute arrangements and details of English houses, even of those which do not belong to the wealthy class. Those luxuries which the richest nobles could not formerly procure at any price, are now at the command of every man of a moderate income. We are, of course, here speaking of really well-built houses; for of late years the demand for 'genteel' villa residences, in the suburbs of London and other large and prosperous towns, has become so great, that speculating builders have been induced to erect houses of the very worst description. They are generally showy, but built only to sell, and mainly of a very unsubstantial character.

The houses of the poorer classes are too often negligently built. In their construction, economy, convenience, and a wholesome ventilation, should be mainly kept in view, and these may be united with as much picturesque beauty as the nature of the materials will admit of without increasing the expense. In cottages of two stories, the upper should be warmed by a flue from the fire in the lower; in order to effect this, the vent ought to be carried up the middle, with its sides as thin as possible. In a single cottage of

twelve or fourteen feet square, the conveniences should consist of a common dwelling room on the ground floor, and a sleeping apartment on the upper floor, which should be partitioned off to separate the sexes.

The English and Scotch cottages differ in their external appearance and arrangement. The walls of the old English cottage were formed of clay, mud, or turf, kept together and strengthened with upright pieces of wood and with wooden braces; the roof was steeply pitched. In order to keep the walls dry, the eaves of the roof were continued downwards beyond the top of the wall and projected from it. The chimneys, which formed the main strength of the building, were generally carried up singly in one or both ends of the building, and for the most part they projected on the outside of the wall. The roof was covered with straw, reeds, or slate. The front walls being low, the windows were made much longer than high, and the long lintel, or head part of the window, was supported by one or more upright pieces called *munnions*, or *mullions*. The frames for the glass revolved on hinges with an upright axis, and were glazed in borders of lead stiffened by cross pieces of wood or iron, called saddle-bars. The best English cottages of recent construction are built of brick and covered with slate. The use of these materials has changed the character of this class of dwellings; and the progress of sanitary knowledge has led to the introduction of numerous improvements in their internal arrangements. In many cottages the chimney-stack forms the principal bearing of the floors and roof.

The Scotch cottage contains two apartments on the ground floor, usually spoken of as 'but and ben'; this is also a matter of necessity, as they are seldom raised more than one story. The material for the walls is most commonly stone; the roof is large and heavy in appearance, and has but a small projection beyond the walls. The windows and doors, being without the projecting label, are not so well protected from the rain; the walls, however, are thick, and the window openings, on account of the size of the stones, are narrow; the windows slide vertically, being placed in a frame. The chimneys are either carried up in one or both gables, or in a partition wall, which separates the two apartments in the length. The old roofs of thatch, turf, or heath, have given place to slate and tile. But the houses in the Scotch cities and towns are built in what are called 'flats,' communicating by a common staircase, and each flat or story containing accommodation for one or more families.

As the French and Italians of the middle classes do not generally live in separate houses like the English, but, like the Scotch middle classes, on floors containing a series of rooms, it follows that the arrangement of their houses differs from that of the English. The staircase, as in public chambers, is common to each floor. The rooms communicate with each other, and generally with a passage or balcony on one side; chimneys are rare, stoves being most commonly used to heat the rooms. In France and Italy the windows are not hung with pulleys and weights, but are formed of two folding glass doors on hinges. The Mezzanino (Mezzanine) is common in French and Italian houses. The houses have generally projecting roofs with often broad overhanging eaves, while in England the gutter is usually

concealed within a parapet wall. French and Italian houses are mostly built of rough stone and stuccoed.

The Spanish houses are very spacious; they have large courts in the interior, and are formed with galleries round the inside of the quadrangular courts: families occupy the separate floors, as in France and Italy.

The houses in many parts of Germany approach nearer to the English in their arrangement than the French and Italian houses. In many places the houses are a framework of wood, and the interstices are filled with unbaked bricks, and are plastered with clay. The mode of heating them in Germany and Switzerland is principally by stoves (*ofen*), which, in the better houses, are so arranged that the domestic feeds the fire without entering the apartment which is heated by it.

The city architecture of Russian houses, both in its effect and arrangement, resembles the architecture of Italian and French houses, except that the roofs are covered with sheet iron painted with vivid colours, mostly green and red. The windows are double.

Various details relating to the practical construction of houses are given under BRICKWORK; BUILDING; CARPENTRY; FOUNDATION; FIRE-PROOF BUILDINGS; and other similar heads.

HOUSE-LEEK. [SEMPERVIVUM.]

HOUSE, LEGAL DEFINITION OF. 'An Englishman's house is his castle,' is a well-known proverb, and the saying is so far true that no house can be legally broken into unless the inmate be charged with a criminal offence. A debtor, for whose arrest a warrant has been obtained, may shut himself in his house and defy the bailiff as long as he pleases. At all events, under no circumstances must the latter use force to obtain admission, but if he can once get in—by any trick or stratagem whatever—he cannot be turned out. [BAILIFF.] In Scotland the law is very different, for there an order may be procured from the Court of Queen's Keys, and a man's house forcibly entered for debt alone.

In defending his house against trespassers and thieves a man must use no more force than is necessary, although in extreme cases even killing the intruder is justifiable.

The offence of assaulting a man in his own house—which is always looked upon as more serious than a common assault—is in Scotland called *Haim-sucken* or *Hamesucken*, but in England there is no peculiar name to distinguish it from other assaults. For the law relating to Housebreaking, see the article on that subject.

HOUSE OF COMMONS. [PARLIAMENT.]

HOUSE OF CORRECTION, called also a Bridewell, is a gaol governed by a keeper, and not under the ordinary charge of the sheriff. Prisoners convicted of felony or misdemeanour, or committed on suspicion thereof, persons awaiting their trial or convicted of small offences, and vagrants, are taken in charge at houses of correction.

HOUSE OF LORDS. [PARLIAMENT.]

HOUSEBREAKING and BURGLARY. The derivation of the word burglary is uncertain. The offence of burglary at common law is defined to be 'a breaking and entering the dwelling-house of another in the night, with intent to commit some felony within the same, whether such felonious intent

be executed or not.' By 1 Vict. c. 86, 'night-time' is declared to be from nine o'clock in the evening till six o'clock the next morning. By dwelling-house is meant the actual and personal residence of a man. If a dwelling-house is feloniously entered at any other time than in the night-time, the offence is simply housebreaking. Burglary is now only punishable by penal servitude for life or for not less than three years, or imprisonment for a term not exceeding two years.

HOUSEHOLD TROOPS are those troops whose especial duty it is to attend the sovereign, and to guard the metropolis. These forces comprise three regiments of cavalry, viz.—the 1st and 2nd Life Guards, and the Royal Horse Guards; and three regiments of Foot Guards, viz.—Grenadier, Coldstream, and Scots Fusilier. On 1st April, 1867, the Household Troops numbered 7270 of all ranks—1317 Life and Horse Guards, and 5953 Foot Guards—and the estimated cost for their pay and allowances during the year 1867–68 was 300,664*l*.

HOWARD, CHARLES, son of William, Lord Howard of Effingham, and grandson of Thomas, second duke of Norfolk, was born in 1536. He succeeded to his father's title in 1573. After seeing much service by land and sea, he was appointed in 1585 lord-high-admiral of England, and had the management of the naval preparations made against the Spanish Armada in 1588. He acquitted himself of this most weighty charge with signal prudence, skill, and bravery. In 1596 he was joined with Essex in the expedition against Cadiz. For this service Lord Howard was created Earl of Nottingham. In 1599 he suppressed the ill-concerted rebellion of the earl of Essex, whom he took into custody. Under the reign of James I. he was employed in several distinguished capacities. He died at the advanced age of eighty-seven, December 14, 1624.

HOWARD, HENRY, EARL OF SURREY, son of Thomas Howard, third duke of Norfolk, was born about the year 1516, and was educated at Christ Church, Oxford. In 1540 he distinguished himself at a tournament held before the court at Westminster, and was soon afterwards created a knight of the garter. In 1542 he served under his father in the army sent against Scotland, and in 1544 accompanied the troops with which the king invaded France. On the surrender of Boulogne in 1546, he was made captain-general and commander of the garrison left for its defence; but in this situation he was superseded by the earl of Hertford, and on his return to England dropped some remarks against the king and council which were reported by his enemies, and led to his ruin. He was accused, on some frivolous grounds, of high treason, was committed to the Tower of London, tried, and found guilty, and on the 19th of January, 1547, was beheaded on Tower Hill.

Surrey's works are principally remarkable as forming an important era in English literature. He far surpassed in smoothness of versification all the poets who had preceded him except Chaucer, as well as all his contemporaries. His sonnets have much delicacy and tenderness, and he was the first to introduce blank verse, in a translation of the 2nd and 4th books of Virgil's '*Æneid*.'

HOWARD, HENRY, R.A., was born January 31, 1769. He became the pupil of Philip Reinagle, R.A.,

and was admitted a student of the Royal Academy, March 27, 1788. On December 10, 1790, he received at the same time the first silver medal for the best drawing from life, and the gold medal for the best historical picture, '*Caractacus, a prisoner, recognizing the dead body of his son*.'

In 1791 Mr. Howard went to Rome, and there painted the '*Dream of Cain*,' his first work for the academy exhibition, which was forwarded to London in 1794.

After his return to London, Mr. Howard exhibited, in 1796, among other subjects of more or less interest, '*the Planets drawing Light from the Sun*,' an idea which he afterwards expanded into one of his most admired pictures, '*the Solar System*.'

In 1801 Mr. Howard was elected an Associate; in 1808 a Royal Academician; and in 1811 he succeeded Mr. Richards as secretary to the Royal Academy. From the year 1796 up to 1814 he had been occupied on a variety of works: on designs for engravings illustrative of the Poets; a number of portraits of private individuals; and many pictures, classical, religious, and historical.

In 1814 Mr. Howard obtained the premium of 50 guineas for the best design for a medal for the Patriotic Fund; and after that time he was employed on designs for most of the principal medals and great seals executed in this country during the remainder of his life. In the same year Mr. Howard exhibited a picture at first called '*Sunrise*,' but since better known as '*the Pleiades*.' In 1818 he exhibited one of his finest works, '*Fairies on the Sea-shore*.' Sir M. W. Ridley, who purchased it, gave him a commission to paint a larger picture of the '*Birth of Venus*,' which was exhibited in the following year. It has been considered one of the finest works of the artist and of the class. Mr. Howard died on the 5th October, 1847, at Bath, in the seventy-eighth year of his age.

HOWARD, JOHN, was born about 1727. His father was a London tradesman, who, dying early, left him in possession of a handsome fortune. In 1756, in a voyage to Lisbon, which he was desirous of seeing immediately after the great earthquake, he was captured by a French privateer. The sufferings which he endured and witnessed during his confinement struck deep into his mind. The impression was renewed in 1773, when, as sheriff of Bedfordshire, he had charge of the prisons of the county. In that year he visited, in two journeys, most of the gaols of England, and accumulated a large mass of information, which, in March, 1774, he laid before the House of Commons. Once actively engaged, he became more and more devoted to this benevolent pursuit, and made many journeys at home and abroad in order to collect information. The first fruit of these labours was a quarto volume, entitled '*The State of the Prisons in England and Wales, with some preliminary observations, and an account of some Foreign Prisons*,' 1777.

The House of Commons seconded his views by the introduction of a bill for the establishment of houses of correction. Mr. Howard, in 1778 and 1779, made other journeys on the Continent and in Great Britain. The results were published in 1780, in an '*Appendix to the State of the Prisons in England and Wales*,' &c. In 1781 and several succeeding years Mr.

Howard continued his tours on the Continent, and visited most of the countries of Europe.

He returned to England in 1787, resumed his home tours, and in 1789 published the result of his late inquiries in another important volume, entitled 'An Account of the principal Lazarettos in Europe, &c., with additional Remarks on the Present State of the Prisons in Great Britain and Ireland.' The same summer he renewed his course of foreign travels, meaning to go into Turkey and the East through Russia. He had, however, proceeded no further than the Crimea when a fever, which he himself believed to be infectious, put an end to his life, January 20, 1790. He was buried at Cherson. An interesting memoir of him by Mr. Hepworth Dixon, contains a succinct view of his admirable philanthropic labours.

HOWDAH or HOUDAH, a seat erected on the back of an elephant.

HOWDEN. [YORKSHIRE.]

HOWE, RICHARD, afterwards Viscount Howe, the second son of Emanuel Scrope Howe, governor of Barbadoes, was born in 1725. At the age of fourteen he left Eton and joined the *Severn*, one of the squadron which, under the command of Commodore Anson, was sent to make war upon the western coasts of Spanish America. He distinguished himself in the West Indies, and on the coast of Africa, which caused his rapid promotion to the rank of captain. On the first of June, 1758, he hoisted his flag in the *Essex* as commodore of the fleet destined to blockade Brest. In the same year he married, and soon afterwards, losing his brother Viscount Howe, he succeeded to his title and estate. In 1759 Lord Howe served as second in command to Sir Edward Hawke, when he defeated the French fleet under M. de Conflans. Peace being proclaimed, Howe occupied a seat at the Board of Admiralty for two years, and then filled the important office of Treasurer of the Navy, and was returned to Parliament for Dartmouth. In October, 1770, he was promoted to be Rear-admiral of the Blue, and Commander-in-chief in the Mediterranean. On a change of ministers, his friends appointed him Admiral of the Blue. Lord Keppel having resigned his office, Lord Howe succeeded him as First Lord of the Admiralty. In three months he was obliged to resign, on another change of the ministry, which restored Lord Keppel. At this time he was created Earl Howe. On the 22nd of June, 1790, he was appointed to the command of the channel fleet. On the 28th and 29th of May, and 1st of June, 1794, an engagement took place in the channel between the British and French fleets, when ten of the enemy's ships were dismantled, seven were taken, three only rejoined the French admiral, and Howe had the glory of towing into Portsmouth six ships of the line.

Lord Howe's health now began to fail; but, notwithstanding his infirmities, he consented to go in person to quell the mutinies that had arisen at Portsmouth, Spithead, &c. With his wife and daughter he spent the rest of his life in retirement. He had declined a pension. He died August 5, 1799.

HOWITZER, a piece of ordnance which differs from what is denominated a gun only in its proportions, the ratio of the length of the piece to its diameter being considerably less than that in the latter kind of arm. It may be considered as interme-

diate between the gun and the mortar, though it is mounted on a gun carriage. It is employed to project solid and hollow shot, loaded shells, carcasses, and case shot. It being comparatively light, the charge of powder is small, and consequently the angle of elevation required is high.

The howitzer is used against troops in the field, in the attack of redoubts or villages, and both in the attack and defence of regular fortresses. A small light gun called the Coehorn howitzer, is also much used for mountain service in India.

HOWLEY, MOST REV. DR. WILLIAM, Archbishop of Canterbury, and Primate of all England, was born at Ropley, near Alresford, in Hampshire, in 1765. He was educated at Winchester, under the tuition of Dr. Warton; and in 1783 he proceeded as a scholar to New College, Oxford, where he was elected fellow in 1785. After passing successively through the different university degrees, he was appointed, in 1809, Regius Professor of Divinity. In 1813 he was promoted to the see of London. In the following year he made his primary visitation as the new bishop of London; and the eloquent charge which he delivered on that occasion produced a deep sensation, especially amongst the Unitarians, whom he represented as 'loving to question rather than learn.' To this Mr. Belsham published a powerful reply, and accused the bishop of promulgating the slavish doctrines of Popery rather than the free spirit of Protestantism. But while exhibiting the principles of intolerance on the one hand, his lordship appears to have displayed a feeling of political obsequiousness on the other. He was one of the most strenuous supporters of the bill of pains and penalties against Queen Caroline, in 1820; and on that occasion he enunciated, with much emphasis, the slavish doctrine that the king could do no wrong, either morally or politically. This uncompromising defence of 'right divine' did not fail to secure the goodwill and patronage of his majesty, George IV.; for on the death of Archbishop Manners Sutton in 1828, his lordship was translated to the archiepiscopal see of Canterbury. The duke of Wellington was then prime minister, and imagined that he could rely on the support of the new primate in carrying the Catholic Emancipation Bill; but he was mistaken; for his grace declared that at his consecration he had sworn to stand by the Church of England; and he denounced the measures of the Government as irreligious and revolutionary. Thus, in 1829, and again in 1831, did the archbishop struggle, first, against emancipation, and next against parliamentary reform, when he declared that from these measures the church and constitution, the altar and the throne, were in danger of certain annihilation. They have, however, long become a part and parcel of the law of the land; and notwithstanding the solemn declarations and dark forebodings of our most reverend prelate, the throne and the altar still remain, and apparently on a firmer basis than ever. The fact is, that although his grace was a learned theologian and an estimable private character, he was neither a statesman, an orator, nor a politician, but a time-serving supporter of 'the powers that be,' and an uncompromising opponent of all liberal progress. He died in 1848, and was interred in Addington Church, near Croydon.

HOWRA, a town on the right bank of the Hooghly,

British India, opposite to Calcutta, of which it may be considered a suburb. It has shipbuilding yards, and is a terminus of the railway from Calcutta to the north-western provinces. (Johnston's *Gazetteer*.)

HOWTH. [DUBLIN.]

HOY. [ORKNEY.]

HOY, a small vessel, usually rigged as a sloop, and employed in conveying passengers and goods from place to place on the sea-coast.

HUCKABACK, a very coarse kind of linen cloth, commonly used for towels.

HUDDESFIELD, a market-town and parliamentary borough in the West Riding of Yorkshire, is situated 7 miles S.E. from Halifax, 26 miles N.W. from Sheffield, and 189 miles N.N.W. from London. At the last census the population of the entire parish was 52,254; of the parliamentary borough only, 34,877. The greater part of the houses are built of a light-coloured stone. The market-place is a large area, surrounded with good houses and shops. The trade of the town derives great advantages from its inland navigation, by means of the Ramsden and Huddersfield canals, both eastward and westward, and from the abundance of coal in the vicinity. The canal connecting the town with the Mersey is carried, at the highest canal level in England, through the chain termed the 'English Apennines' by a stupendous tunnel, $3\frac{1}{4}$ miles long.

The parish church was a small ancient structure, which was taken down in 1835, when a new one was erected in the perpendicular Gothic style. There are several other churches of the establishment, and there are also many places of worship for Methodists, Independents, Unitarians, Quakers, and Roman Catholics. The Sunday-schools and religious and educational societies connected with the town and county are liberally sustained. The Philosophical Hall is a Grecian building, which was completed in 1837. There are also subscription and law libraries, and a commercial news-room. The Infirmary is a large and elegant stone building in the Grecian Doric style, erected in 1830. The town also contains a national proprietary college, collegiate school, gymnasium hall, commodious cloth hall, banking company, several branch banks, &c. The manufactures comprise broad and narrow cloths, kerseymeres, flushings, serges, cords, pilots, mohair and sealskin cloths, and 'fancy woollen goods.' Silk spinning and cotton spinning and doubling are carried on, and the manufacture of cotton warps. The railway communication is very good, there being direct lines to the metropolis and the principal manufacturing towns, and good access to all parts of England, by means of the Great Northern and Manchester, Sheffield and Lincolnshire, London and North-Western, and Lancashire and Yorkshire railways. The borough returns one member to Parliament, and is also a polling place for the county. The number of registered electors in 1866 was 2138; and the population, 37,066.

HUDSON, HENRY, is eminent among those early navigators who sought a shorter passage to China than the circuitous route round the Cape of Good Hope. Nothing is known of him before 1607, when he was employed by some London merchants to command a ship fitted out to prosecute that object. After three unsuccessful voyages he undertook a fourth, in hopes of discovering a north-western pas-

sage, in April, 1610. In the course of June and July he sailed through the Strait, and discovered the Bay, both of which have since been called after his name. [HUDSON'S BAY.] The insufficiency of provisions exposed him and his companions to great hardship, and at last proved fatal to his scheme. The men became discontented and insubordinate, and while they were in the Strait on the voyage home, some of the boldest of the mutineers seized the captain and eight of his staunchest followers, and sent them adrift in an open boat. They were never afterwards heard of.

HUDSON, RIVER. [NEW YORK.]

HUDSON'S BAY is an extensive gulf on the eastern side of North America, and connected with the Atlantic Ocean by Hudson's Strait. Its length is 850 miles (between 51° and 66° N. lat.). It is 600 miles across in its widest part. The southern portion, called James' Bay, extends nearly 240 miles, and at its mouth (near 55° N. lat.), between Cape Jones, E., and Cape Henrietta Maria, W., it is 140 miles wide. The coasts are generally high, rocky, and rugged, and in many places precipitous, except along the south-western shores between Cape Henrietta Maria and Cape Churchill, where they are low and swampy, and frequently exhibit extensive strands. The depth of water in the middle of the bay has been taken at 150 fathoms, but it is probably greater. In the northern part lies Southampton Island, at the mouth of the Strait. The shores of the bay possess an inhospitable climate, being very much colder than places in Scotland in the same latitude. At Fort York, near the western shore, in lat. $57^{\circ} 2'$ N., the thermometer sometimes descends to 50° below zero; brandy freezes to a solid substance in rooms with a constant fire; and but for supplies obtained from more temperate regions existence would be impossible.

Numerous rivers run into Hudson's Bay, the largest being the Nelson. The Hudson's Bay Company have various 'ports,' or settlements on its shores.

HUDSON'S BAY COMPANY was incorporated by Charles II. under a royal charter dated the 2nd of May, 1670. The charter was given in favour of Prince Rupert, who was the first governor, the duke of Albemarle, Earl Craven, Lord Arlington, Lord Ashley, Sir John Robinson, Sir Robert Vyner, Sir Peter Colleton, Sir Edward Hungerford, and others; and it states that these parties having at their own great cost and charges undertaken an expedition to Hudson's Bay, for the discovery of a new passage into the South Sea, and for finding some trade in furs, minerals, and other commodities, had 'already made such discoveries as to encourage them to proceed further in their design, by means whereof there may probably arise great advantage to us and our kingdom.' With this view the charter grants to the company in perpetuity the sole trade and commerce of all those seas, straits, bays, creeks, and sounds, in whatever latitude they may be, that lie within the entrance of Hudson Straits, together with all the lands and territories upon the countries, coasts, and confines of the seas, bays, &c., aforesaid. The company thus obtained the privilege of exclusively trading with the Indians in the vast and not well-defined region called Rupert's Land, which comprised all the country that had rivers flowing into the great

inlet from which the company takes its name. This association founded several establishments, and has ever since prosecuted the trade under the direction of a governor and committee of management, chosen from among the proprietors of the joint-stock, and resident in London. The company's charter not being confirmed by Act of Parliament, it was considered that all British subjects were entitled to engage in the trade with those regions; and in conformity with this notion the North-West Company was formed in 1783, and proved a powerful competitor. This company had a settlement, called Fort Chippewyan, so far west as the Lake of the Hills, in 110° 26' W. long.; and some of the Indians trading with them came from beyond the Rocky Mountains. A great degree of jealousy and hostility arose between the respective agents of the two companies, which more or less impeded the operations of both for many years, until in 1821 a junction of the two was effected, and the trade has since been prosecuted peacefully and successfully.

In 1825 a license of exclusive trade with the Indians, over all that portion of the north-west territory not included in the charter, was granted to the company for twenty-one years. This license was renewed in 1835. The power of the company was thus greatly increased, and all the Indian territories opened to the operations of the association, which *now virtually ruled through seventy-five degrees of longitude, from Davis' Strait to Mount St. Elias; and through twenty-eight degrees of latitude, from the mouth of the Mackenzie to the borders of California. This extensive tract of country has, however, been gradually brought under the pale of civilization; and the company, though retaining its commercial supremacy, has lost much of the legal monopoly. The state of Oregon was given up to the United States in 1841; in 1859 the island of Vancouver, and likewise the district of British Columbia, were colonized, and the license withdrawn from the company. This does not in any way affect the original charter of Rupert's Land, and the company would seem to have lost rather a formal privilege than actual influence. In fact it is believed by competent authorities, that even if the fur trade were thrown entirely open, a long time would elapse before the trading of the company would cease to hold its pre-eminence, because of the wide-spread ramifications of their system, and because also of the ties of various kinds which bind the native hunters to them.

The company's vast territories are ruled by a governor-in-chief, invested with large powers, who, with the chief factors or agents, constitute the members of a council, which meets annually in June to review the events of the past year, and make arrangements for the ensuing one. The company send out yearly large quantities of blankets, cloth, guns, ammunition, knives, and miscellaneous articles, of which about one-third is for the use of their servants, and two-thirds for barter to the Indians for furs. The total number of persons in the company's employ is about 3000.

In 1863, a change was effected in the constitution of the company which in no way affected the charter, and the effect of which has been generally misunderstood. At that period the opening up of

the north-west territory attracted public attention in England, and it was generally surmised that the Hudson's Bay Company, from its wish to protect the trade in furs, was an obstruction to the settlement of that country. The duke of Newcastle, then secretary for the colonies, participated to some extent in that belief, and under his auspices an association of speculators came forward, who agreed to purchase the whole of the stock of the company at a stipulated price, provided they were insured so much of the stock as would give them a preponderance in the company. The governor and committee then in office having agreed to these terms on the part of the company, the whole stock was taken at the price agreed on by the International Financial Society, who fixed the capital at two millions sterling, which was issued to the public in 100,000 shares of 20*l.* each. Since then the company has greatly extended its operations, and will, no doubt, do so still more hereafter. Negotiations have been opened by Canada for the acquisition of the company's rights, and it is probable that in a few years immigration will have extended to the district of the Saskatchewan and the other territories east of the Rocky Mountains, extending along the southern frontier of British North America. Postal and telegraphic communication has been established between Canada and British Columbia across the company's territory. Ministers of the gospel of every denomination are protected and encouraged, and there is a bishop of the Church of England in the diocese of Rupert's Land.

In the year 1864 the exports from the Settlements of the Hudson's Bay Company to the United Kingdom were as follows:—

	Quantities.	Value.
Castor, ...	2,673 lbs. . .	£691
Feathers for beds, . . .	37 cwts. . .	311
Isinglass, ...	29 " . . .	961
Oil, train or blubber, . .	51 tuns. . .	2,368
Skins—Bear, ...	6,865 . . .	8,581
" Beaver, ...	77,886 . . .	29,208
" Fisher, ...	3,295 . . .	5,039
" Fox, ...	16,543 . . .	15,555
" Lynx, ...	3,350 . . .	1,703
" Marten, ...	102,208 . . .	71,120
" Musquash, ...	256,345 . . .	6,676
" Otter, ...	9,649 . . .	6,024
" Wolf, ...	6,170 . . .	3,290
" Other sorts, ...	— . . .	7,489
All other articles, . . .	— . . .	4,241
Total, ...		£163,257

The above includes goods to the amount of 44,103*l.* from British Columbia, all of which were, however, exported by the company. The imports in the same year from Great Britain to the Hudson's Bay Settlements, exclusive of British Columbia, were valued at 74,777*l.*, and consisted chiefly of clothing and provisions. [FURS AND FURRIERY.]

HUÉ, or HUÉ-FO, the capital city of the empire of Anam, Cochín-China, on the Hué river, about 10 miles from its mouth, in the China Sea. The population is not correctly known, but is supposed to be about 100,000. It has no parallel in the East, having been regularly fortified in the European style early in the present century. Its walls, mounting

numerous cannon, are upwards of five miles in circumference, and inclose an inner citadel, with the palace, and spacious barracks, large public granaries, an arsenal, and magazines, which, with other public buildings, are supplied with water by numerous canals, faced with masonry, and crossed by fine bridges. A garrison and fleet of galleys are usually stationed here.

HUE AND CRY was the old common-law process of pursuing with horn and voice all felons and such as had dangerously wounded another. This process is still used in England as a means of arresting felons without the warrants of a justice of the peace. Hue and cry may be raised either by the precept of a justice of the peace, or by a private person who knows of the felony, who should acquaint the constable of the vill with the circumstances and the person of the felon; if the constable is absent, hue and cry may be made without license. When hue and cry is raised, all persons are bound to join in the pursuit and assist in the capture of the felon. A constable, also, who has a warrant against a felon may follow him by hue and cry into a different county from that in which the warrant was granted, without having the warrant backed. The pursuers are justified in breaking the outer door of the house where the offender actually is, and are not liable to any punishment or suit if it should appear that the hue and cry was raised by mistake, but the person raising the hue and cry wantonly and maliciously may be severely punished as a disturber of the public peace.

A printed sheet called the *Hue and Cry* is issued three times a week from the police court, Bow Street, which contains descriptions of property stolen, notices of robberies, and descriptions of soldiers who have deserted. Copies of this paper are sent to the police offices throughout the country. The *Hue and Cry* is published at the expense of the Home office, and costs about 1200*l.* a year.

HUELVA, a seaport in the south of Spain, capital of the province of Huelva, is situated at the confluence of the Odiel and the Tinto, 63 miles W.S.W. of Seville. It has a good transit trade with Cadiz and Seville, and exports large quantities of fruit and matting to England and Portugal. The population is 8423.

HUGUENOTS was the name given to the early followers of the Reformed or Calvinist religion in France. The origin of the word has been variously accounted for, but was most probably a corruption of the German *eidgenossen* ('confederates,' or 'bound together by an oath'). By some it is said to be derived from the early meetings having been held on a heath near Tours, haunted by the ghost of Hugo Capet. The Roman Catholics used the name of Huguenots as a word of reproach against heretics. The word is now obsolete, and has been replaced by that of 'Réformés,' which is usually given to the disciples of Calvin, while the more general name of Protestants includes Lutherans. The wars and persecutions of the Huguenots are noticed in the articles *BARTHOLOMEW, ST.*; *CHARLES IX.*; *COLIGNY*; and *HÔPITAL, DE L.*, but for full details of the history of the Huguenots the reader is referred to Dr. G. De Félice's '*Histoire des Protestants de France, depuis l'origine de la Réformation jusqu'au le temps présent*,' of which there is more than one English

translation. D'Aubigné's '*History of the Reformation in the Sixteenth Century*' also contains some valuable information respecting the Huguenots.

HULL, or KINGSTON-UPON-HULL, is a borough and county of itself. It is the chief town in the East Riding of Yorkshire, and a port of first-class magnitude, situated on the north side of the estuary of the Humber, where it is joined by the river Hull. It is distant 174 miles N. from London. Hull returns two members to Parliament. The number of electors on the register in 1866 was 5566.

For municipal purposes, Hull is divided into seven wards, represented by thirteen aldermen and forty-two councillors. The mayor has the singular honour of having two maces and two swords, one given by Richard II., the other by Henry VIII. The boundaries of the parliamentary and municipal borough are identical.

This place took its name of Kingston from its purchase by Edward I., who saw the great natural advantages of its position, and determined on the foundation of a fortified town and port.

The town, under the name of Mytonwyk, appears to have been of importance in the time of Athelstan. In the civil war of Charles I. it was the first to close its gates against the king, and it successfully sustained two sieges by the royal troops in 1642 and 1643.

The citadel, which was on the east bank of the river Hull, at its junction with the Humber, has been pulled down, and its site is now converted into streets and shipbuilding yards. The garrison has been removed to the village of Paull, six miles lower down the Humber, where a new fort has been erected in a more commanding position. Hull has several good streets; and extensive warehouses, backed by narrow lanes, border the river, along which the town and suburbs extend for nearly two miles from the Humber.

The docks, built upon the site previously occupied by fortifications, communicate with each other, and have an aggregate length of 1807 yards, covering 87½ acres, including the West Dock, 17 acres, which was constructed in 1866. They are surrounded by broad quays and large warehouses, have a depth varying at high tide of from 20 to 27 feet, and are crowded with the shipping of all nations.

Hull has the advantage of being connected by railway with all the manufacturing towns of Yorkshire and the Midland counties, and forms the great outlet for the exportation of their goods. The number of vessels registered as belonging to the port in 1867 was 617, of 86,258 tons 'urthen. The total number of ships which entered the port in 1866 was 4111 (1,076,403 tons), two-thirds of which were engaged in the foreign and colonial trade, and one-third coastwise. The clearances in the same year amounted to 4018 (1,001,559 tons). The customs revenue for 1866 was 339,463*l.*, ranking in England, in this respect, next after London, Liverpool, and Bristol. The principal imports are timber, corn, wool, iron, flax, hemp, tallow, hides, pitch, spirits, sugar, tobacco, and wine; the exports, woollen and cotton manufactures, yarn, earthenware, hardware, and metals. The coasting trade is highly important, there being much traffic in coal. There is also a very extensive transit trade between the north of Europe

and America, *viâ* Liverpool. The merchants of Hull were the first in England to embark in the northern whale fishery, but this trade has nearly ceased. The town is an important steam packet station, and communicates many times weekly with London, Yarmouth, Leith, Berwick, Aberdeen, Hamburg, Rotterdam, Copenhagen, Havre, Dunkirk, and Antwerp; also with the other chief European ports.

In the town are large cotton and flax mills, extensive iron shipbuilding yards, manufactories for machinery, chain cables, ropes and canvas, potteries, tanneries, soap and chemical works, corn and oil mills. The manufacture of oil-cake is also carried on to a considerable extent. There is a branch of the Bank of England, and several other banks.

Among the chief public buildings are the royal institution and museum, guildhall, new exchange, custom-house, dock, pilot, excise, post, and stamp offices, public rooms, infirmary, Trinity house and Trinity almshouses. A handsome new town-hall was opened in January, 1866; and in the same year a merchant seamen's orphan asylum was completed. There is an equestrian statue of William III. in the Market Place, which is covered with leaf gold. The Wilberforce statue surmounts a fine fluted Greek Doric column, on a square pedestal. In the People's Park (about 14 acres in extent), is a seated marble statue of Queen Victoria; and there is a bronze statue of the late Dr. Alderson in front of the infirmary.

The most important educational establishments are the Trinity House School, where thirty-six boys receive a nautical education, the Hull Grammar-School, Proprietary College, Coggan's charity school for girls, many national and other schools, and various institutes.

The benevolent establishments include the general infirmary, founded in 1782, the Trinity House, instituted in 1369 for the relief of decayed seamen, the Charter House, or Maison Dieu, for the relief of the poor, several dispensaries and asylums.

The Botanic Garden, established in 1811, is about a mile from the town.

The Holy Trinity Church is the most ancient in Hull, and is very large. It is 272 feet long from east to west, and is a beautiful and ornate cruciform Gothic structure, with a pinnacled tower 140 feet in height. It was restored internally and externally in 1864; and St. Mary's Church was also enlarged and completed in the same year. There are ten other churches, and fifteen dissenting chapels.

The rapid progress made by this flourishing port within the last half century, is apparent from the following statistics. In 1821 it contained 9004 houses; in 1831, 11,888; in 1841, 13,927; in 1851, 18,428; in 1861, 20,581; and in June 1865, 24,768. In 1821 the number of inhabitants was 44,965; in 1831, 54,112; in 1841, 67,095; in 1851, 82,502; in 1861, 97,661; and in June, 1867, nearly 107,000. In 1836 the rateable value of property in Hull was 176,559*l.*; in 1861, 238,504*l.*; and in 1864, 280,000*l.* In 1836 the burthen of the vessels frequenting the port of Hull upon which dock dues were levied by the Hull Dock Company was 503,165 tons; in 1860, 1,215,203 tons; and in 1864, 1,216,815 tons. The value of the goods exported from Hull in 1859 was 12,980,587*l.*; in

1863 it was 13,556,254*l.*, and in 1865 it had increased to 15,865,528*l.* This amount is exclusive of coal and coke exports.

HULLMANDEL, CHARLES JOSEPH, inventor of the lithographic art, was of German descent, and born in London in 1789. He first commenced his experiments on the then newly-discovered art of lithography in Great Marlborough Street, in the year 1818, and there printed his own drawings taken from sketches made during his residence on the Continent. The success attending his efforts attracted the attention of the artistic world; and such was the encouragement he received, that he determined on devoting his entire time to the study and practice of lithography. The art being mainly dependent on the judicious application of chemical principles, he placed himself as a student under Professor Faraday. The first great improvement he effected was that of a graduated tint printed over a black and white impression, which imparted to it the appearance of a print on tinted paper, and gave a vast impulse to the encouragement of the art. It was the means of bringing out some of the splendid productions of Harding, Stanfield, Nash, and other eminent artists. Mr. Hullmandel also succeeded in producing various other improvements, such as printing in colours by means of different stones, and also printing from drawings made with a brush and liquid ink. This art he called Lithotint, for which he procured a patent. For this he received the reward which Louis Philippe of France had previously offered for the discovery. Several splendid works of art, executed by this process, soon afterwards made their appearance, which established the fame of the inventor, and confirmed the value of his art. He died in 1851.

HUMBER. [YORKSHIRE.]

HUMBOLDT, FRIEDRICH HEINRICH ALEXANDER, BARON VON, a celebrated naturalist and traveller, descended from an ancient, wealthy, and noble family in Pomerania, was born at Berlin on the 14th September, 1769. His father, Major Humboldt, served in the Seven Years' War as aide-de-camp to the duke of Brunswick, and was afterwards chamberlain to the king of Prussia. When he was only fourteen years of age, Alexander went with his brother William to Berlin to complete his studies under Læflier and Fischer for classics, Wildenow for botany, and Endel, Klein, and Dohm for political economy and philosophy. Between 1786 and 1788 he studied at the University of Frankfort-on-the-Oder, and in 1788 he repaired to Göttingen, where he studied philosophy, history, and the natural sciences under Heyne, Eichhorn, and Blumenbach. At Göttingen he became acquainted with George Forster, Heyne's son-in-law, who accompanied Captain Cook in his second voyage round the world, and who inspired his young friend with a desire to study the productions of the tropics. In 1790 he accompanied Forster and Genz in a tour through Germany, Holland, England, and along the two banks of the Rhine; and he published the result of his tour in a work entitled 'Observations sur les Basaltes du Rhin,' &c., which appeared at Berlin in 1790. At the close of 1790 he went to Hamburg, where he studied foreign languages and bookkeeping in the commercial school of Bosching; and though his family intended him for some office under the

government, his mother yielded so far to his passion for science as to send him to the mining academy at Freiberg, to extend and perfect his geological knowledge under Werner, who had then for one of his pupils the celebrated Baron Von Bach. The reputation which Humboldt had now acquired was such as to obtain for him the government appointment of assessor of the council of mines at Berlin, and soon afterwards that of director-general of the mines in the principalities of Anspach and Bayreuth. With the knowledge acquired in the discharge of these duties he wrote and published in 1793 his 'Specimen Floræ Freibergensis,' a work in which he described the cryptogamic and subterranean plants of the district. M. Galvani of Bologna had about this time founded a new science on the convulsive twitches of the nerve in the leg of a frog when touched with a knife. Humboldt rushed into this new field of inquiry with a zeal bordering on extravagance. He made wounds in his back by means of cantharides, in order that the metals of the galvanic circle might be better applied to the muscle. The results of these researches were published in 1796, and the French translation of the work, which appeared in 1797, entitled 'Expériences sur l'Irritation Nerveuse et Musculaire,' was enriched with notes by the illustrious Blumenbach. Upon the death of his mother on the 20th November, 1796, Humboldt had resolved to undertake some great voyage of discovery. With this view he sold his property in Prussia, and made a tour in Switzerland and Italy to examine the mountainous regions and volcanoes of those interesting countries. Shortly after his return to Berlin he set off for Paris, in order to purchase the instruments which were necessary for the execution of his plans, to study its valuable collections of natural history, and profit by the society of the illustrious men who then adorned the academies of the Institute. Working with Arago, Cuvier, and Gay-Lussac, he acquired in their laboratories and observatories the practical knowledge which he needed; and on their recommendation the directory authorized him to join the expedition under Captain Baudin, which was about to circumnavigate the globe, with permission to disembark wherever he chose. Owing to the war in Germany and Italy, the government withdrew the funds which had been granted for the expedition; and having become acquainted with Aimé Bonpland, who was to have accompanied Baudin as naturalist, it was arranged that Humboldt and he should visit the north of Africa and explore the chain of the Atlas mountains. When at Marseilles, the ship which was to convey them had not arrived after two months' delay. They set off, however, for Tunis; but being prevented from landing by the hostility of that state to France, they resolved to spend the winter in Spain, previous to a journey to Egypt. On their arrival at Madrid, the naturalists were received with the highest distinction. The king gave them permission to travel through all the colonies of Spanish America, and to visit the Marianne and Philippine islands on their return to Europe; and having eagerly accepted of this liberal offer, they quitted Madrid in May, 1799. On the 5th of June they set sail from Corunna in the ship *Pizarro*, and after visiting the peak of Teneriffe, they reached Cumana,

the capital of New Andalusia, on the 16th of July. After verifying his instruments, and making other preparations for his journey, Humboldt and Bonpland travelled through New Andalusia and Spanish Guiana, determining the geographical position of the most important stations, studying their natural history, observing atmospheric phenomena, and examining the antiquities of the country, and the manners and customs of the inhabitants. This exploration of South America was continued for five years, and whether we estimate it by the romance of personal adventure, or the value of scientific research, it is without a parallel in the annals of civilization. After having for seventy-five days navigated, in an Indian canoe, the Orinoco, the Apure, the Atrabapo, the Rio Negro, and the Cassiquari, they rested at Angostura in June, 1800; and after being detained for two months by the English blockade, they went at the end of the year to Havannah in Cuba, where they remained for above ten weeks. Quitting Cuba in March, 1801, with the view of joining Captain Baudin's expedition to the Philippine isles, and learning that this plan was impracticable, they went to Carthagena, ascended the Amazons in a voyage of fifty-four days, and after visiting various interesting regions, arrived on the 6th January, 1802, at Quito, where they spent five months. On the 23rd June, accompanied by Carlos Montufar, they ascended Chimborazo, nineteen thousand three hundred feet above the sea, and the highest point of the Andes ever reached by man. After visiting Lima in Peru, they embarked about the end of December, 1802, for Guayaquil, descended to Acapulco, and passing by Fasco and Cuernavaca, they arrived in April at Mexico. In this interesting kingdom they spent more than a year, visiting the mines of Moran, the singular waterfall of Regla, and on the 17th September, 1803, the mud volcano of Jorullo, one of the wonders of the New World. From Mexico our travellers went to Havannah, and from thence to the United States, visiting Philadelphia and Washington. Laden with large and valuable collections, they quitted America on the 9th July, 1804, landed at Bordeaux on the 3rd August of the same year, and repaired to Paris to prepare for the publication of their travels. Here Humboldt remained till March, 1805, when he visited Italy and Berlin in succession, and returned to Paris in 1807, where he remained for twenty years, refusing the most liberal offers from the Prussian government. During his short visit to Berlin we find him occupied in observing the solstices and equinoxes, and in recording the variations in the horizontal magnetic needle every half hour during several days and nights. His object in these observations was to study the nocturnal portion of the diurnal oscillation, but he unexpectedly detected the most capricious changes in the needle, which occasionally exhibited sudden and rapid movements, to which he gave the name of *magnetic storms* (accompanying the aurora borealis), a subject which has been prosecuted with great success by M. Arago and our distinguished countryman General Sabine. About the end of 1807 appeared the first parts of his great work, entitled 'Voyage aux Regions Equinoctiales des Nouveau Continent pendant les années 1799-1804, par A. De Humboldt et A. Bonpland.' A translation of

the personal narrative, by Helen Maria Williams, was published in five volumes in 1814-21; and between that year and 1817 the other parts were published in French and Latin, and drawn up by several distinguished individuals—Olmans for astronomy, Arago and Gay-Lussac for chemistry and meteorology, Cuvier and Latreille for zoology, Vauquelin and Klapproth for mineralogy, and Kunth for botany. In 1822 Humboldt accompanied the king of Prussia to the congress at Verona, and, along with Gay-Lussac, he made a scientific tour in Italy, visiting Venice, Rome, and Naples. On his return he spent some time in England, and in 1823 he published his 'Essai Geognostique sur le gisement des roches dans les deux hemispheres.'

In obedience to the urgent solicitations of the king, our author took up his residence in Berlin in 1826, and was welcomed in the warmest manner by all classes of the community. In the winters of 1827-1828 he delivered his celebrated course of lectures on the physical phenomena of the universe, which was afterwards expanded into his 'Cosmos.' In the spring of 1829, when Humboldt was about to enter his fifty-ninth year, he was invited by the emperor of Russia to undertake at his expense, and principally for the benefit of science, a journey to the eastern provinces of his kingdom, and to Central Asia, having for its main object the advancement of geology and terrestrial magnetism. Having eagerly accepted of this liberal offer, he associated with himself the celebrated naturalist, M. Ehrenberg, for the department of zoology and botany, and Gustavus Rose for chemistry and mineralogy, while he himself was to conduct the astronomical and magnetical observations. With M. Menschenin, a Russian engineer, as their guide and interpreter, the travellers left St. Petersburg on the 20th May, 1829, and embarking at Novogorod on the Volga, they passed by Casan to the Kirghese Steppe, visited Bolgari, the Tartar capital, and went by Persia to Ekatherineberg on the Asiatic side of the great Uralian chain. Advancing along the Southern Ural they arrived at Astrakan and the Caspian, and returning through the country of the Don Cossacks to Moscow, they reached St. Petersburg in November, 1829, having accomplished in six months a journey of two thousand three hundred and twenty geographical miles. The results of this great expedition have been given in two works—the one by Gustavus Rose and the other by Humboldt. The work of Humboldt, published in Paris in three volumes in 1843, is entitled 'Asie Centrale, Recherches sur les chaines de Montagnes, et la Climatologie comparée.' This work, dedicated to the emperor of Russia, led to the establishment of those magnetical and meteorological observations in various parts of the empire, and in the British colonies in Canada, Australia, South Africa, and St. Helena, by means of which our distinguished countryman General Sabine has been led to such important generalizations. In April, 1835, Humboldt suffered a severe loss in the death of his brother William, who expired in his arms. In the beginning of 1842 he accompanied the king of Prussia to England, and was present at the christening of the Prince of Wales. In 1843 and 1844, when in the seventy-fifth year of his age, he composed his remarkable work, dedicated to the king of Prussia,

entitled 'Cosmos: Essai d'une Description Physique du Monde,' which was published at Stuttgart and Berlin in 3 vols., 1847-51, and which was translated into English, under the patronage of its author, by Mrs. General Sabine, and also by Miss Otté, and into French in 1848-57 by MM. Faye and Goluski, under the auspices of M. Arago.

The intellectual services of Humboldt, which our limited space has enabled us but imperfectly to record, were honoured with rewards seldom conceded to the cultivators of literature and science. Among the decorations which he received from different sovereigns, that of grand officer of the legion of honour was doubtless the most welcome. In 1850, on the death of our illustrious countryman Mr. Cavendish, he was elected one of the eight foreign associates of the Academy of Sciences of the Institute of France, and he was an honorary or corresponding member of all the leading scientific institutions in the Old and New World. He was chancellor of the Prussian order *pour le Merite*, founded by Frederick the Great, the decorations of which have been, on his recommendation, bestowed on several of the most distinguished of our countrymen. In 1858, while occupied with the completion of his latest work, Humboldt was reminded of his own mortality by the death of his friend and fellow-traveller, Aimé Bonpland, who, after escaping from the tyranny of Dr. Francia, died at San Borgia in Brazil, in the eighty-sixth year of his age. In a short time after the intelligence of this event had reached him, Humboldt was seized with an illness which carried him off at Potsdam on the 6th of May, 1859, when he was within a few months of his ninetieth year. The loss of such a man, who was beloved by all ranks of society at Potsdam and Berlin, was felt as a public calamity, and every honour was paid to his venerated remains.

HUMBOLDT, KARL WILHELM, BARON VON, was born at Potsdam, June 22, 1767, and studied law in the universities of Göttingen and Jena. He was thirty-three when he published his first production, which was a critical essay on Göthe's poem of 'Hermann and Dorothea;' but this work at once established his fame, and it is still considered as a model of æsthetical criticism. In 1802 Humboldt was appointed resident, and a few years afterwards, minister plenipotentiary at the Holy See. In 1812 he was sent as ambassador to Vienna, and afterwards discharged the functions of minister plenipotentiary of Prussia, together with Hardenberg, at the Congress of Vienna. He continued his diplomatic career at Frankfurt, where he made himself conspicuous through his conciliatory eloquence in the delicate business of dividing Germany among its princes, and afterwards as ambassador at the court of St. James'. In 1819 he was appointed minister and a privy councillor at Berlin. Humboldt and the ministers Von Beyme and Von Boyen tried to persuade the king to be faithful to those liberal principles which he had proclaimed in 1813, and to introduce a general national representation. Unable to stem the king's policy, Humboldt, Beyme, and Boyen tendered their resignation, and Humboldt retired to Tegel, where he henceforth devoted all his time to literature. He died April 8, 1835. During forty years he had enjoyed the well deserved reputa-

tion of one of the greatest linguists of Europe. With the exception of one large work which he left unfinished, Humboldt composed only minor works, consisting of critical essays, poems, translations from the Greek, and remarks on the oriental languages, which he published at different periods. The greater part of them was collected by his brother Alexander, and published under the title, 'Wilhelm von Humboldt's Gesammelte Werke,' Berlin, 1841, 4 vols. 8vo.

HUMBOLDTINE, mineral *oxalate of iron*. This substance occurs crystalline and massive. The crystalline form is undetermined, but is yellow and opaque. The massive variety occurs in small, flattish, reniform pieces, of a fine earthy structure; colour greenish yellow.

HUMBOLDTITE. This mineral is a *boro-silicate of lime*. It occurs crystallized. Primary form an oblique rhombic prism; colour white and yellowish white. Opaque. Specific gravity, 2.99.

HUME, DAVID, was born at Edinburgh on the 26th of April, 1711. His father's family was a branch of that of the earl of Home, or Hume; but Hume inherited only a slender patrimony. His father died when he was very young, and his mother destined him for the law; but for this he showed no inclination, and it was eventually given up.

In 1737 he repaired to Bristol, with some recommendations to eminent merchants, but in a few months, finding that scene totally unsuitable to him, crossed over to France with a view of prosecuting his studies. He first went to Rheims, and thence to La Flèche in Anjou; and at these two places he composed his 'Treatise of Human Nature.' It was published in London in 1738, but fell dead-born from the press. In 1742 he published at Edinburgh the first part of his Essays, which was on the whole favourably received.

In 1745 Hume went to live with the young marquis of Annandale as a guardian, and afterwards acted as secretary to General St. Clair, principally during his military embassy to Vienna and Turin.

On his return from the Continent he resided with his brother in Scotland, and composed his 'Political Discourses,' and his 'Enquiry concerning the Principles of Morals.' These two works were published in 1752. In the same year he was appointed librarian to the Faculty of Advocates. He now formed the plan of writing the 'History of England.' Priding himself much on his own impartiality, he was bitterly disappointed, when, on the appearance of the first volume, he was accused on all hands of onesidedness.

In the interval between the appearance of the first and that of the second volume of his History, he published his 'Natural History of Religion,' against which a violent pamphlet was written by Warburton. The second volume of the 'History of England' was published in 1756. 'This performance,' he says, 'happened to give less displeasure to the Whigs, and was better received. It not only rose itself, but helped to buoy up its unfortunate brother.' 'The History of the House of Tudor' was published in 1759; and the two volumes, containing the earlier English history, which completed the work, in 1761.

He availed himself, in 1763, of an invitation from the earl of Hertford to accompany him on his embassy to Paris, where his literary fame secured him much attention. When Lord Hertford was, in 1765,

appointed Lord-lieutenant of Ireland, Hume remained at Paris as *chargé d'affaires* till the arrival of the duke of Richmond. He returned to England in the beginning of 1766, accompanied by Jean Jacques Rousseau, who, however, but ill requited his hospitality, and the year after was appointed Under-secretary of State. He held this appointment about two years, and then returned to Edinburgh. He died August 25, 1776, in his sixty-sixth year.

The editions of Hume's 'History' are numerous. The best edition of his philosophical works is one published in Edinburgh, in 1826, in four vols. 8vo. J. H. Burton, Advocate, Edinburgh, published a Life of Hume, some years since, with many letters never before published.

HUME, JAMES DEACON, was born April 28, 1774, at Newington in Surrey, and was educated at Westminster School.

At the age of sixteen, Mr. Hume was appointed to a clerkship in the London Custom House, and at an unusually early age he was selected to fill an office of much responsibility in the department. His value came to be highly appreciated by the government, and in 1823 he was appointed to reduce into one simple code the many hundred statutes (upwards of 1500) which at that time formed the Custom-house legislation. Three of the most valuable years of his life were devoted to the task; for the performance of which Mr. Hume was presented by the treasury with the sum of 5000*l.* over and above the salary of his office, from the duties of which he had been relieved during the period devoted to the task; and from that time scarcely any question of importance which had reference to the trade of the country was decided without his opinion having first been obtained. At length, in July, 1829, his services were wholly transferred to the Board of Trade, where an office was created for him as Joint-Assistant Secretary. Mr. Hume died January 12, 1842, in the sixty-eighth year of his age.

HUME, JOSEPH, the champion of economy in national finance, and for thirty-seven years foremost in the ranks of parliamentary liberalism, was born at Montrose in the year 1777. His father, a shipmaster, owner of two vessels, died when he was five years old. His mother, a woman of strong mind and great good sense, found herself unable, after a trial, to carry on her husband's business, and she, by industry and skilful management, reared her family on the profits of a cruckery shop. Joseph had the education which is seldom denied, when a parent is anxious for it, to a child-denizen of a Scottish burgh; and the deficiencies of the instruction given him he endeavoured to repair by his own exertions. Among his notable schoolfellows was his friend and fellow-worker of after-life, the late John Mill, the historian of British India. The medical profession was his own choice. Apprenticed at fourteen to a surgeon at Montrose, he migrated three years later to the University of Edinburgh, completed his medical studies, and in 1795 was admitted a member of the Edinburgh College of Surgeons. He made a voyage to India in 1796, and in 1797, after attending the hospitals, was admitted a member of the College of Surgeons in London. He now entered as an assistant-surgeon the service of the East India Company. He began his career with the

equipment of an indomitable energy, and of a disposition to be helpful and useful in any emergency. Even in the course of his first passage out he volunteered to supply the place of the purser, accidentally incapacitated, and discharged his extempore duties so well, that at the conclusion of the voyage he was presented with a testimonial by the captain, officers, and passengers; thus he landed with a reputation ready made. Observing that few of the company's servants knew the languages in use in Hindustan, he applied himself to master them. With this knowledge, and with his inborn aptitude for accounts and business, he soon added to his medical duties those of Persian interpreter, postmaster, and paymaster of the division to which he was attached on the breaking out of the war with the Mahrattas in 1803. He worked so hard and so successfully that when he returned to England in 1808, it was as the possessor of a fortune of 30,000*l.* or 40,000*l.* In 1809 he made a tour of minute observation through the United Kingdom, visiting every place of manufacturing importance. He passed the greater part of the years 1810–11 in foreign travel, visiting Spain, Portugal, Sicily, Egypt, Turkey, Greece, &c., keeping his eyes ever open to any practical arrangement which might be carefully imported into this country. It was at that early period that, struck by what he had seen at Palermo (as he once told the writer of this memoir), he pressed on the authorities at home the system of extramural internments, which has only recently been carried into effect. To these continental researches, he added a careful study of the constitution and political history of his own country. On his return to England in 1812 he entered the House of Commons as member for Weymouth, a vacancy occurring through the death of Sir John Johnstone. Mr. Hume was passing through the lobby of the house when Bellingham shot Mr. Percival, and it was he who seized the assassin, and held him fast until he was arrested. He had arrived from India with a strong belief in the excellence of the government as it was, and he took his seat on the ministerial side of the house. His views, however, were soon modified, and his advocacy of a liberal commercial policy so dissatisfied the trustees of Sir John Johnstone that they refused to return him to the new Parliament of 1812. His first recorded speech in the house was one in favour of popular education. For some years afterwards he devoted himself to political and social action out of Parliament, cultivating the acquaintance of advanced reformers such as Francis Place, and promoting the establishment of savings banks and of Lancasterian schools. During this period of absence from the House of Commons Mr. Hume began his exertions in the court of East India proprietors, where, in 1813, he fought single-handed the battle of free-trade. In 1818 he was returned to Parliament for the Montrose burghs, which included his native town, and he continued to represent them until 1830. With his varied knowledge, ever open to increase, his indefatigable industry, and his imperturbable temper, he soon took rank in the house as a liberal leader of no ordinary calibre. Other men might have larger intellects or greater oratorical gifts, but the usefulness of Joseph Hume was never vitiated by a suspicion that he wished either to play

the part of a demagogue or to grasp the spoils of office. To name the political and social 'causes' of which Mr. Hume was the unwearied advocate in the House of Commons and out of it, would be to recapitulate the programme of the liberal party from the commencement to the close of his parliamentary career. Financial reform was from first to last his peculiar question. His immense knowledge of the details of government departments was something startling, and his demands for retrenchment and economy were not of the vague kind which it is so easy to cultivate, but based on and supported by facts and figures familiar to him as the alphabet. When a 'job' or a piece of extravagance was proposed, 'What will Joseph Hume say?' was an expression which became proverbial. In the pre-reform era, one of his most notable achievements was the repeal which he procured of the combination laws; and when the reform bill came, he saw ministers of the crown endeavouring to gain popularity by carrying out the reforms which he had long promoted almost single-handed. It was his exertions—long, laborious, and costly—that gave the death-blow to Orangeism in the army and out of it in the years 1835–36. It was he who moved for the appointment of the import duties committee of 1840, which led to the tariff reforms of Sir Robert Peel. It is to Mr. Hume that the public owes the throwing open of such places as Hampton Court and Kew Gardens. He was the spokesman of every grievance, public and private; and to the last his house in Bryanston Square was the resort of all who had injuries to be redressed, or suggestions for improvement and reform requiring an advocate. During the latter years of his life he enjoyed, without the embarrassments of office, the position of a veteran minister; and, nearly the oldest member of the house, where he had never made an enemy, he was respected and esteemed by the leaders of all parties in Parliament. It should be added that though his name was identified with financial economy and retrenchment, Mr. Hume was always not only ready, but eager to support every claim on the public purse which had in view the social or educational elevation of the people, or indeed any object of genuine public utility; he may be said to have created the present system of lighthouses. He died at his seat, Burnley Hall, in Norfolk, on the 20th of February, 1855. From 1830 to 1837 he had represented the county of Middlesex, which he exchanged in 1837 for Kilkenny. In 1842 he was re-elected for the Montrose burghs, and continued to represent them till his death. The new writ for the Montrose burghs, rendered necessary by his death, was moved for by Lord Palmerston on purpose to deliver a eulogium on the character and career of their last representative. His lordship dwelt specially on the singular disinterestedness of Mr. Hume's long and laborious political career, and said of him that 'he took the lead in almost every branch of improvement and in every measure of improvement which has of late years been carried into practical operation.' Mr. Hume had married, in 1815, a daughter of the late Hardin Burnley, and to his public merits added the private virtues of an excellent son, husband, and father.

HUMIDITY is that property of a substance by which it communicates to a body in contact with it

some of a liquid which it may have absorbed; and the term is commonly applied to the atmosphere when it is in a state to deposit moisture upon bodies in it.

The humidity of the atmosphere is caused in a great measure by the evaporation of water from the seas, lakes, &c., of the earth; and the quantity of moisture which a volume of air is capable of containing depends upon the temperature. If that be increased, the power of receiving more vapour increases; and the atmosphere becoming saturated with moisture, if the temperature be suddenly lowered, a precipitation of water takes place.

The humidity of the atmosphere generally decreases from the surface of the earth upwards; and when the density of the lower strata is great, the clouds ascend into the drier regions, where they are readily absorbed. This circumstance accounts for the fact that, when the mercury rises in the barometer, the weather frequently becomes fair.

The effects of humidity on the dimension of bodies are various: when a watery vapour penetrates between the twisted fibres of cordage, which are vegetable materials, the cordage swells out transversely, and thus becomes shortened; while cords made of animal substances become relaxed by humidity and increase in length. Most salts absorb water, and thereby increase in weight.

HUMIRIACEÆ, a natural order of plants belonging to the syncarpous group of polypetalous Exogens. There are three genera belonging to this order, *Humirium*, *Helleria*, and *Sacoglottis*.

H. balsamiferum, a tree forty feet in height, is a native of Guiana. Its bark is thick, and abounds with a red balsamic fluid, which resembles styrax in smell; after it has exuded from the tree it becomes hard and transparent, and when burnt affords an agreeable odour. The negroes and natives of Guiana use the bark in slips for the purpose of flambeaux; they also use the wood in building their houses. The other species of *Humirium*, and also those of *Helleria* and *Sacoglottis*, yield resinous juices.

HUMMING-BIRD. [TROCHILIDÆ.]

HUMULUS LUPULUS, a perennial plant belonging to the natural order *Urticaceæ*, is a coarse twiner inhabiting hedges in many parts of Europe, and is also found apparently wild in the United States of America.

The female flowers, termed cones, strobili, or catkins, of *Humulus Lupulus*, when ripe, constitute hops, which, independent of their employment in brewing, are of considerable utility in medicine.

The valuable principle of the hop is called *Lupuline*, and is contained in little glands on the fruit. The superiority of the hop, as an ingredient in our malt liquors, depends upon the fact of its containing within itself several distinct and independent elements of activity, which the bitter herbs that have at different times been employed as a substitute do not possess. The bitter principle imparts to the beverage a tonic quality and an agreeable flavour; while at the same time an aromatic ingredient adds a warmth and stimulating property, and modifies the bitterness: it likewise contains an astringent principle (tannin), the effects of which are to precipitate the vegetable mucilage, and thus to remove from the beer the active principle of its fermentation: every attempt therefore to substitute an ordinary bitter

for that of the hop must necessarily fail, unless a compound can be so artfully constructed as to contain in due proportions the principles of bitterness, astringency, and aroma.

The aromatic bitter gives to the hop a very marked power over the digestive organs when debilitated. A narcotic property has also been ascribed to this plant, which is denied to it by some writers, who attribute the intoxicating power of beer entirely to the alcohol and carbonic acid which it contains. Yet there can be no doubt that tincture of hops, and even extract of hops, possess sedative powers, and often procure quiet and sleep where opium cannot be borne. Decoction does not seem to be a judicious mode of preparation, and should not be practised. Lupuline has been administered alone, but this does not possess any advantage over the tincture.

HUMUS (Lat. 'vegetable mould'), a name given by chemists and scientific agriculturists to that dark and crumbly soil which has been formed by the remains of plants exposed to the different stages of decomposition of rottenness. Thus when roots, wood, straw, or dung, lie upon or in the earth, they absorb moisture; and first becoming brown and soft, they afterwards assume a blackish-brown colour. Finally they become black and pulverulent, as may be easily seen on examining the superstratum of the soil in forest lands. In truth, vegetable fibre may be regarded as the principal producer of humus; such as leaves, straw, moss, peat, &c. When these substances turn to putrefaction and decay, their colour becomes dark, and they are converted into carbonic acid and water, which can be absorbed as nutriment by plants; for the fallen leaves and decayed roots, as well as the insects and worms which feed upon them, become subject to decomposition and decay when the vital principle is gone. Then the carbon they contain is converted into carbonic acid; and the humus, when air and moisture can act upon it, is by degrees still further decomposed, and thus continually furnishes fresh supplies of carbonic acid to the roots of plants. Of all the ingredients of soils humus possesses the strongest power of absorbing the moisture, oxygen, and other constituents of the atmosphere favourable to vegetation.

HUNDRED. [SHIRE.]

HUNDRED, in commerce, a numerical amount which varies in different countries. In England it is usually estimated at 112 lbs. In Riga and Elsinore, the great hundred is twenty gross, or 2880 pieces. In Belgium the hundred of articles, in general sales, is 164 pieces. The hundred deals or planks in Christiana are reckoned at 127; in Sweden at 120; in Westwyck at 124; and in some other of the timber-exporting places of the north, at 132.

HUNDRED, TRIBUNAL OF THE, was a legislative body at Carthage, instituted, like our House of Commons, for the purpose of balancing or counteracting the power of the senate and nobility.—The *Senate of Five Hundred* was also a celebrated tribunal at Athens, whose business was to deliberate on all measures of state, or matters of law, intended to be submitted to the people for adoption. They were liberally maintained at the public expense, and were required to meet every day for the despatch of business.

HUNGARIAN LITTORALE. [CROATIA.]

HUNGARY. Under the denomination of *Hungarian Hereditary Dominions* were formerly comprehended Hungary Proper, Slavonia, Croatia, Transylvania, Dalmatia, and the Military Frontier. After the unsuccessful revolution in 1849, the limits of the old kingdom of Hungary were much contracted, but the recent reconciliation between Hungary and Austria will tend to restore it to its ancient importance. It is inclosed by the Carpathian mountains on the north, Transylvania on the east, the Banate and Slavonia on the south, and Styria, Lower Austria, and Moravia on the west. It lies between 46° and 49° 35' N. lat., and 16° and 26° 20' E. long. The area is about 68,000 square miles, and the population nearly 11,000,000.

The country consists chiefly of an immense plain, and possesses generally a clay soil of extraordinary fertility; but along the rivers large swamps occur, owing to their low borders being so readily overflowed. There are also large tracts of sand, called *puzta*, interspersed with soda lakes, which dry up in summer and leave their beds incrustated with the mineral. From their general character they appear to have anciently belonged to the bed of an extensive inland sea. But both the sand and swampy tracts are rapidly diminishing in size, in consequence of extensive works energetically carried on for their reclamation. The climate varies considerably. In the districts nearest the mountains it is so cold that the winter may be said to continue from October to May, but in the southern districts snow seldom lies on the ground more than two or three weeks. The level tracts in the eastern part often suffer greatly from drought. Although, from want of care, in the swampy districts ague is prevalent, the climate on the whole must be regarded as healthy, and favourable to the development of physical strength.

Nearly the whole of Hungary lies within the basin of the Danube. The Theiss, itself a branch of the Danube, is one of the chief rivers, and its basin may be considered as forming a distinct part of Hungary. The Drave, the Raab, the Leitha, the March, the Waag, the Gran, &c., flow into the Danube. The Zagya, Sajó, Hernád, Bodrog, Koros, Maros, Gzemos, Temes, &c., flow into the Theiss. Of the lakes the most considerable are the Plattensee [*BALATON*], 46 miles long, and 3½ miles mean breadth, and the Neusiedler, about 24 miles long, and from 3 to 7 miles broad, both of which lie in the west part of the country. Many canals have been made in different tracts of Hungary, partly to drain the marshes and partly for the purposes of commerce.

In the abundance, variety, and value of its natural productions Hungary excels almost any country in Europe. Corn is the main product of agriculture, especially in the south. The Hungarian wheat is of the finest quality, and well known in the French and English markets. Fruit grows everywhere, even at the foot of the Carpathians. There are whole forests of cherry, plum, and chestnut trees. In the south, lemon and orange trees blossom the whole summer in the open air. The grape is most abundant; the wine of the Hegyalla district is renowned by the name of Tokay. The average yearly production of wine in Hungary is estimated at 400,000,000 gallons, of which at least one-third is available for export, and is now coming into favour

in the English markets. Tobacco is also extensively cultivated; but the crops of corn, grapes, and tobacco would all soon be very much increased by free trade, political security, and greater facilities of transport.

Of domestic quadrupeds the horned cattle are some of the finest in Europe. The breed of sheep has been much improved, and horses, swine, and poultry are largely reared. Bears, wolves, and various birds of prey are met with in the forests. Hungary has extensive works in metals of almost all kinds, except tin; and it produces likewise a great variety of precious stones, such as amethyst, agate, opal, jasper, Hungarian diamonds, garnets, &c.

The inland trade of the kingdom is as active as the means of communication will permit, and the foreign commerce is of importance, and rapidly increasing in extent. The exports consist of the natural produce of the kingdom; the imports chiefly of manufactures. The roads in many parts are still very bad, but extensive railway communication has been opened between the chief towns, and the resources of the country are in process of extensive development. A sound and equitable system of taxation, coupled with the recent revival of constitutional rights, will, no doubt, soon effect still greater changes.

Perhaps no country of the same extent contains such a variety of nations as Hungary. The Magyars, or proper Hungarians, were originally an Asiatic people; there are also Wallachians, Armenians, Germans, Italians, Jews, Servians, Russniaks, Slovacs, Croats, and Wends. The inhabitants, except the Jews, are Christians. The Roman Catholics have three archbishops and seventeen bishops. The United Greeks have four bishops. The Non-united Greeks have an archbishop and seven bishops. The Protestants have no bishops, but are governed by superintendents and synods.

Education, especially in its lower branches, is rapidly extending. Schools exist in every district. There are also a few academies, many gymnasia, a lyceum at Erlau, a university and two schools for philology at Pesth, a famous mining school at Schemnitz, and many others.

The constitution of Hungary is given in the article **AUSTRIA**.

History.—The oldest known inhabitants of Hungary were a nation of nomadic barbarians, originally issuing from Scythia or Western Tartary. They do not appear to have been known to the Romans until the beginning of the third century, at which time the Latins called them Pannonians. Under Attila, not unjustly named the 'Scourge of God,' they made an irruption into Gaul, and conquered its most opulent towns, and were rapidly sweeping towards Paris when Ætius, the Roman general, defeated them with immense slaughter near Troyes, in Champagne, in 451. Attila then withdrew into Pannonia; but soon recovering his losses, he poured, like a torrent, into Italy, captured its richest towns, ravaged its fairest provinces, and was about to carry his victorious arms into Gaul, when death arrested his career in the year 454.

Upon Attila's decease the Huns assumed the name of Hungarians, but of their progress during the fall of the Western and the rise of the Eastern empires, and of their wars, irruptions, and forays which are said to have occurred between the third and tenth cen-

turies, history preserves no authentic record. But it is certain that German missionaries carried a knowledge of the religion of the cross into their savage wilds early in the eleventh century, when Stephen, their chief, who had married the Emperor Henry's sister, was baptized, and received from the pope the title of the 'apostolic king.' He endeavoured to strengthen his throne and consolidate his kingdom by creating a hierarchy and an aristocracy. For this purpose he divided Hungary into ten bishoprics and twenty counties; the counts and bishops forming a council of state, with whose concurrence this sagacious monarch prepared a system of government, whose main features were long preserved. But the prosperity of the country was long impeded by the struggles which broke out in King Stephen's reign between the dominant forces of paganism and Christianity. Andrew I. (or Andreas) reigned from 1046 to 1061, when he fell in a battle with his brother Bela, who succeeded him on the throne. St. Ladislaus, by his genius and virtue, irradiated a period of Hungarian history which otherwise would present only a dark record of war and bloodshed. He subdued Slavonia and Croatia in 1089, and Calomann conquered Dalmatia in 1102. The boundaries of the kingdom were still further extended by Bela II. and Emeric, the former of whom subdued Bosnia, and the latter Servia.

A valuable impetus was communicated to the prosperity of Hungary by the introduction in 1148, under the auspices of Geysa II., of German colonists, who laid the foundation of its manufacturing wealth; and the gradual progress of commercial and industrial ideas exercised a favourable influence on the Magyars, who abandoned their wild rude life on the tented plain, and assembled in towns under the shadow of the law. Something of the grace and elegance of French civilization was introduced by Margaret, sister of King Henry of France, who married Bela III., an able and patriotic monarch. A severe blow, however, was given to the national welfare by a terrible irruption of the Mongols about the middle of the thirteenth century, and it required a long course of years to heal the wounds inflicted by those barbarous hordes.

Bela III. was succeeded by his son, Andreas II., who died in 1235. Then came Bela IV., and, in 1290, Andreas III., the last monarch of the Arpad dynasty, which became extinct at his death in 1301. A disastrous interregnum ensued, which was terminated by the interference of the papal power on behalf of Charibert. Charibert gained his crown by the sword, and preserved it by the sword, recovering the provinces of which the kingdom had been deprived, and adding to it Moldavia. This energetic sovereign was succeeded by less competent rulers, and Hungary was convulsed with internal feuds which continued almost uninterruptedly for several generations. A civil war was maintained between the nobles and the commons, during the reigns of Ladislaus V. and the Corvins, which afforded the Turcomans an opportunity of invading the distracted country. Led by Soliman the Magnificent, the Moslems completely annihilated the Hungarian forces in 1526. Their king, Louis II., was slain, and when the victorious soldiers of the crescent withdrew from the ravaged land, they bore with them

two hundred thousand Christian captives into slavery.

In 1526, the Hungarian states unanimously elected Ferdinand I., emperor of Germany, to the Hungarian throne. But the country still remained disturbed by the enmities of the Protestant and Catholic factions, and the Turks held many of its principal strongholds. For a century and a half, as the bulwark of Christendom, the frontier land between Christian Europe and Mohammedanism, it was subject to their invasions, which drained it of its best blood and exhausted its resources.

Leopold was elected king in 1655. As he attempted to encroach upon their liberties, the Hungarians revolted, and in consequence many of their leading nobles perished on the scaffold at Vienna. To complicate the misfortunes of the country, it was again invaded by the Turks, who, assisted by a large body of the insurgents, under the celebrated Tekeli, swept through Hungary, and invested the Austrian capital. The ruin of the Austrian empire seemed imminent, but this peril to Christendom was averted by the genius of Sobieski, king of Poland, who hastened to the succour of the emperor, and under the walls of Vienna gained a complete victory over the Moslems.

Hungary now submitted to the imperial crown, which, in 1687, was declared hereditary in the house of Hapsburg. It remained for many years tranquil and prosperous; and when the coalition of France, Bavaria, and Prussia threatened the Empress Maria Theresa with the loss of all her dominions, with the shout of 'Moriatur pro rege Maria Theresa,' the loyal Magyars drew their swords in her cause. She died in 1780, and was succeeded on the Hungarian throne by her son, Joseph II., emperor of Germany. In 1790, Peter Leopold became king, but reigning only five months, his eldest son, Francis, assumed the crown.

During the long wars of Napoleon the Hungarians ungrudgingly contributed their men and money to the defence of the Austrian empire; the Diets being convoked for no other purpose than to grant supplies, and be dismissed as soon as they spoke of grievances. But when Napoleon's power was crushed on the field of Waterloo, they naturally expected as a recompense for their sacrifices the social and constitutional reforms which the kingdom greatly needed. On the other hand, Austria was desirous of absorbing Hungary as an integral part of the empire, and of sweeping away the rights and privileges secured to her by the compact of 1687. To resist this unprincipled attempt the Hungarian party was formed in 1827, who continued for twenty years their patriotic exertions, and by their firmness baffled the intrigues of the Austrian government.

In 1847 the direction of the patriotic party was assumed by Louis Kossuth, a man of genius, political sagacity, and courage, who, gifted with extraordinary powers of eloquence, soon obtained a vast ascendancy over the minds of his countrymen. Under his leadership, the Hungarians demanded a responsible ministry, freedom of the press, and annual diets or parliaments. The French revolution of '48 had shaken nearly every European throne, and the emperor was in no position to disregard the voice of Hungary. He conceded all she asked, and, for the

first time for three centuries, the Magyars beheld at Pesth a truly national government.

As soon as Austria had shaken off her first alarm, she began to consider how she should undo what she had done, and recall the liberties she had reluctantly granted. For this purpose she secretly encouraged Jellachich, the ban of Croatia, to invade Hungary with his Serbs and Croats, hoping to profit eventually by the successes he might gain. Discovering the imperial designs, Hungary prepared for war; and the Diet voted funds for raising an army of 200,000 men. Both parties now stood unmasked. The emperor loaded favours upon Jellachich, who crossed the southern frontier of Hungary on the 9th of September with an army of 60,000 men. On his approach to Pesth, he was met by the Hungarian volunteers, strong in the consciousness of a just cause, and suffered a total defeat.

The imperial authorities now threw themselves actively into the struggle. They dissolved the Diet, appointed Jellachich military governor of Hungary, and declared the whole kingdom under martial law. The troops of Austria were poured into the country, in the belief that the 'rebellion' would be speedily crushed. One hundred and thirty thousand men, under Prince Windischgratz, constituted, indeed, a force to which, at first, the Hungarians could offer no resistance, and town after town fell into the hands of the Austrians. The Diet then retired to Debreczin; and Görgei, the commander-in-chief of the Hungarian levies, concentrated his army behind the Theiss. Elate with fond hopes, the emperor now issued a proclamation on March 4, 1849, declaring the national existence of Hungary terminated; as a corollary on which startling proposition, Görgei suddenly led his troops across the Theiss, dashed upon the Austrians, and in a series of engagements which extended over ten days drove back the enemy from point to point, until he finally crushed them at Godollo. Windischgratz was immediately removed from his command, and his successor evacuated Hungary with the wrecks of the imperial army.

On the 16th of April the Diet declared Hungary independent, and appointed Louis Kossuth governor. This step appears to have wounded the *amour propre* of Görgei, though he offered no open opposition; but thenceforth it can hardly be doubted that he played a traitor's part. Had he immediately marched upon Vienna he would assuredly have secured his country's freedom; but he elected to move towards Buda, and afforded Austria time to summon her troops from Italy, and to invoke the aid of Russia. In the month of June the combined imperial armies poured into Hungary from north and south, from east and west. An attack, however, which they hazarded upon Görgei's intrenched camp, near Komorn, was repulsed with a loss of 3000 men; and it is probable that his great military talents might still have been exerted on his country's behalf, but for his sudden and ill-advised removal from the post of commander-in-chief. It is true that in the following August Kossuth and his colleagues retraced their steps by placing the sole power in his hands as Dictator of Hungary; but the slight rankled in the mind of a man who was as vain as he was able, and he basely revenged himself by selling his country to Austria; for, ten days subsequent to his elevation, he

unconditionally surrendered his whole army, 32,000 men, with 144 pieces of artillery, to the Russian commander, at Villagos.

There was now no resource for Hungary but submission. The leading nobles solicited the emperor's clemency; Kossuth, Bem, Guyon, and others, too closely implicated in the rebellion to expect any mercy, made their way into Turkey. Austria pressed for their surrender; but the Ottoman government, supported by England and France, resisted the demand; and Kossuth afterwards repaired to England, where he was enthusiastically welcomed.

Komorn, the last stronghold of the Hungarian patriots, capitulated in October, 1849, and the whole of Hungary bowed beneath the Austrian yoke.

It is not, perhaps, for the interests of Europe that the land of the Magyars should have an existence separate and distinct from that of the Austrian empire; and it would probably be impossible for her to maintain her independence for many years. But every lover of liberty will sympathize with her courageous efforts to secure the advantages of a constitutional government, and the restoration of the rights guaranteed to her by the very treaty which confers her crown on the house of Hapsburg. What she failed to obtain by force of arms, she has now, however, obtained from Austria's necessities. The catastrophe at Sadowa opened the eyes of the emperor and his advisers to the fatal weakness of the empire, and it became their first care to effect a durable reconciliation between the crown and its Hungarian subjects. On June 8, 1867, the emperor was crowned at Pesth as king of Hungary, with a pomp and enthusiasm which recalled former and happier times, and took the oath of allegiance to the Hungarian constitution. All the principal demands of the Hungarian constitutionalists have been conceded by the Austrian cabinet under the advice of the emperor's sagacious premier, Baron von Beust, and the country has obtained the control of her own finances and militia, her rights of local self-government, her own Diet, and separate administration. In fact, her relations to Austria now in some respects resemble those of Ireland to England before the Union; and they have already much strengthened the position of Austria as a first-rate European power.

HUNGERFORD. [BERKSHIRE.]

HUNS, HUNNI, the name given by historians to several nomadic Scythian tribes which devastated the Roman empire in the fifth century. They inhabited the plains of Tartary near the borders of the Chinese empire for several centuries before our era, and it was to put a stop to their incursions that the Chinese built their great wall about two centuries before Christ. In after times they became divided into the Northern and Southern Huns. The northern Huns, being defeated by the Chinese about A.D. 93, emigrated westward as far as the Volga, where they defeated the Alani. They then encamped in the plains between the Volga and the Tánais, and as far south as the ridge of the Caucasus, where they remained for more than two centuries. Under the Emperor Valens they first crossed the Cimmerian Bosphorus, drove before them the Ostrogoths and Visigoths, and obliged the latter to cross the Danube, when the emperor granted them lands in Thrace. The Huns had frequent wars with the Romans. [ATTILA.]

After the death of Attila the various tribes under his sway quarrelled among themselves, and being attacked by the Goths they were driven back beyond the Tânaïs. Part of them settled in Pannonia, to which they gave the name of Hungary; but the present Hungarians, or Magyars, came from a different immigration.

HUNT, JAMES HENRY LEIGH, a celebrated poet, essayist, and critic, was born at Southgate, in Middlesex, 19th October, 1784. He received his education at Christ's Hospital; and his poetical talent displayed itself at such a singularly early age, that before he left school he had written a somewhat large number of verses, which his father published by subscription in 1801, under the title of 'Juvenilia.' Mr. Hunt next became clerk to his brother Stephen, an attorney, and then a clerk in the war-office, which he left in 1808, and became editor and part proprietor of the *Examiner* newspaper, which had just been started by his brother John. They were both tried for political libel in 1811, acquitted and tried again, and sentenced to pay a fine of 500*l.*, and to undergo two years' imprisonment. The libel consisted of the term 'a fat Adonis of fifty' as applied to the Prince Regent. The penalties were borne with patience and fortitude, and all offers on the part of the government to remit them on certain easy conditions were sturdily rejected. After the expiration of the term, Mr. Hunt, a sufferer in health no less than in fortune, returned to his old post, and continued to write as before for the *Examiner*, which long enjoyed the distinction of being the most ably edited and the most independent among the weekly metropolitan press. Mr. Hunt's editorship brought him into contact with several of the leading literary men of the day; and among the authors whose acquaintance he formed were Campbell, the two Smiths, Keats, Shelley, Coleridge, Hazlitt, Lamb, and Byron. In 1821 a new phase opened in Hunt's career. The cause of liberty was, it was thought, in danger of betrayal, and required its friends to be more active; and at Byron's invitation, Hunt determined to transfer the *Examiner* to other hands, and to proceed to Italy with a view to establishing, in conjunction with the author of *Childe Harold*, Hazlitt, and others, a journal in the interest of reform, to be christened the *Liberal*. Hunt describes in his 'Autobiography' the difficulties in which he personally stood in regard to a co-operation in the proposed undertaking. His wife was ill; he himself was ill; he had a large family; and his circumstances, not improved by government prosecutions, were not too flourishing. Altogether he was considerably embarrassed. At length the step was taken. He embarked in November, 1821. 'It was by Shelley's advice,' he says, 'that I acted; and I believe if he had recommended a balloon, I should have been inclined to try it.' Four chapters of the 'Autobiography' are devoted to an interesting narrative of Hunt's Italian experiences, and a good deal of space is occupied by gossip and anecdote. He remained in the peninsula four years, a portion of which time he and his family spent under Lord Byron's roof, and the juxtaposition was attended, as might have been expected, by occasional jars. On his return to England, Mr. Hunt resumed his literary labours, chiefly in the shape of contributions to serials, and in periodical works, some

of which were his own speculations. Among these were the *Literary Examiner*, 1817; the *Companion*, 1828; the *Tatler*, 1830-32, and the *London Journal*, 1834-35; and his talents gradually introduced him to the notice of persons able and willing to serve him. Mr. Hunt, before his visit to Italy, had published Nos. 1 to 4 of a quarterly review called the *Reflector*, and one hundred numbers of the *Indicator*, 1819-21.

His other principal works are—'The Feast of the Poets,' 1814; 'The Descent of Liberty,' a mask, 1815; 'Bacchus in Tuscany,' trans. n. d.; 'Hero and Leander,' n. d.; 'Story of Rimini,' 1816; 'Ultra-Crepidarius,' a satire on W. Gifford, 1819; 'Amyntas, a Tale of the Woods,' 1820 (from Tasso); 'Recollections of Lord Byron,' 1828; 'Sir Ralph Esher,' a romance, 1832; 'Captain Sword and Captain Pen,' poem, 1839; 'Legend of Florence,' play, 1840; 'The Palfrey,' poem, 1842; 'Christianism,' 1846; 'Men, Women, and Books,' a selection from his uncollected prose writings, two vols., 1847; 'The Town,' 1848; 'Autobiography,' three vols., 1850; 'Religion of the Heart,' 1853; 'Stories in Verse,' 1855; 'Old Court Suburb,' 1855. It was the intention of Mr. Hunt, had he been spared a little longer, to have republished the 'Religion of the Heart'; and there is a copy of this book, corrected in many places, and with 'Cardinomia, or Religion of the Heart,' added to the title in the author's hand. In 1847 Lord John Russell procured Mr. Hunt a pension on the civil list of 200*l.* a-year; and this reward, which he had amply won by his old political services and sacrifices, contributed with Shelley's commuted bequest to place him in tolerably comfortable circumstances. His later years were passed in tranquil seclusion and domestic privacy. It was his fortune to outlive the majority of those with whom he had associated at the outset of his career. He saw Keats, Shelley, Byron, Hazlitt, Lamb, and Coleridge sink successively to their graves; and although he did not offer in himself any striking example of longevity, he became at last almost a stranger to the men whom he saw around him, one of a generation which had prematurely vanished. Years rolled on, and his own time came. 'August 28 [1859], at the house of Charles Reynell, Esq., Putney, aged seventy-four, Leigh Hunt, Esq.,' forms a record of the melancholy event which the declining health of the deceased had led his friends for some time to anticipate. He died without pain, and death came so quietly that the sick man was hardly conscious of its approach; and his interest in life remained to the last. Those who wish to form a favourable, or even a fair estimate of Leigh Hunt, will judge him by his earlier productions (1813-20): the publication which will make his name live is the 'Story of Rimini,' 1816. Such as have only read his works are apt to form a very imperfect notion of the accomplished author; for they can know nothing of the riches and charms of his discourse, his gentleness of character, his forgiving nature, and his large heart. One of the noblest of modern political martyrs, he was also one of the most charitable and inoffensive of mankind. In person Hunt was tall and slender, and remarkably erect, even as an old man, in his gait. His hair, bleached by age, was in his younger days jet-black; and his features, though not handsome, were full of

intelligence. His dark, searching Indian eyes were peculiarly expressive, and there was a fire in them which was quenched only with life.

A selection from his Letters and Correspondence was published in 1862 by his son, Mr. Thornton Hunt.

HUNTER, JOHN, was born in 1728, at Long-Calderwood, a village near Glasgow, where his father possessed a small farm. Being the youngest of ten children, and his father dying when he was young, his education was almost entirely neglected. His whole time was devoted to the amusements of the country till he was seventeen years old, when he went to stay with his brother-in-law Mr. Buchanan, who was a cabinet-maker at Glasgow. Hunter worked at the trade for nearly three years. At the end of that time, hearing of the great success which his brother [HUNTER, WILLIAM] had met with in London as an anatomical and surgical lecturer, he wrote to offer him his services as assistant in the dissecting rooms. His offer was accepted, and in 1748 he commenced his anatomical studies, in which he at once distinguished himself both by his ardour and his skill. In 1749 Hunter became the pupil of Cheselden, then surgeon to Chelsea Hospital, where he attended for nearly two years, and in 1751 he went to St. Bartholomew's Hospital, and attended the practice of Mr. Pott. In 1753 he entered as a gentleman-commoner at St. Mary's Hall, Oxford, intending to practise as a physician: but he seems soon after to have given up this idea, for in 1754 he entered as a surgeon's pupil at St. George's Hospital, in the hope of becoming at some future time a surgeon at that institution. In the same year his brother made him his partner in the school, and he delivered a part of each annual course of lectures till 1759, when his constant and severe labours in anatomy, to which he had lately added comparative anatomy and physiology, began to affect his health so seriously that it became advisable for him to resort to some milder climate. With this view he obtained an appointment as staff-surgeon, and early in 1761 proceeded to Belle-Isle with the armament ordered to lay siege to that town. He afterwards went to Spain, and remained in active duty till the end of 1763, when a peace was negotiated, and, his health being completely restored, he returned to London, and commenced practice.

At first Hunter met with little success in his profession. His manners were rough, and he paid but little attention to his practice, regarding it only as a source from which he might obtain the means of carrying on the scientific investigations to which he was far more attached, and which he had steadily pursued while in the army. To defray the expenses which these entailed he again commenced lecturing on anatomy and surgery; but notwithstanding the talent and extensive knowledge which his lectures evince, they were little appreciated, and he never had a class of more than twenty pupils. Every year however, added to his reputation, and in 1767 he was elected a Fellow of the Royal Society, and in 1768 surgeon to St. George's Hospital. The latter appointment was of the greatest value to him; it increased his income, both by adding to his surgical reputation, and by enabling him to take pupils, from whom he received large fees. Among his pupils were

Jenner, with whom he remained throughout his life on terms of the closest intimacy, and Sir Everard Home, whose sister he afterwards married. From the time of his appointment to St. George's, Hunter's life was occupied with a constant and laborious investigation of every branch of natural history and comparative anatomy, physiology, and pathology, to all of which he devoted every hour that he could snatch from the requirements of an increasing surgical practice. In 1773 he suffered from the first attack of the disease of the heart of which he ultimately died. In 1776 he was appointed surgeon-extraordinary to the king; and soon afterwards inspector-general of hospitals, and surgeon-general. For many years after, however, his health seemed pretty good, and he was subject to slighter returns of the disease only when much excited or fatigued; but in 1785 the attacks became more frequent, and he was obliged to leave London. In the following years he became gradually more debilitated, and the slightest fit of anger was sufficient to induce severe spasms. In October, 1793, he was engaged in warm disputes with his colleagues at the hospital; and a remark being made by one of them at a meeting of the governors, on the 16th of the month, which Hunter regarded as an insult, he left the room that he might repress or at least conceal his rage, and had scarcely entered the adjoining apartment when he fell dead in the arms of Dr. Robertson, one of the physicians of the hospital.

John Hunter's museum consisted, at the time of his death, of upwards of 10,000 preparations, illustrative of human and comparative anatomy, physiology and pathology, and natural history. The principal and most valuable part of the collection, forming the physiological series, consisted of dissections of the organs of plants and animals, classed according to their different vital functions. He had a beautiful collection of nearly 1000 skeletons; of objects illustrative of natural history, consisting of animals and plants preserved in spirit or stuffed, of which he left nearly 3000; of upwards of 1200 fossils; and of monsters. The pathological part of the museum contained about 2500 specimens, arranged in three principal departments: the first illustrating the processes of common diseases and the actions of restoration; the second the effects of specific diseases; and the third the effects of various diseases arranged according to their locality in the body. Appended to these was a collection of about 700 calculi and other inorganic concretions. The museum was sold after Hunter's death. The government gave 15,000*l.* for it, and presented it to the College of Surgeons, London, by whom it has been greatly augmented and maintained.

For several years before his death Hunter had been anxious to form a complete catalogue of his collection, and to embody in one large work the results of all his labours and observations. He died when he had completed but a small portion of his design, and left only the materials, with which his successors might have completed a work which would undoubtedly have been the most valuable of its kind ever published. The formation of the catalogue was intrusted to Sir Everard Home, the brother-in-law and only surviving executor of Hunter; but from year to year he deferred his task, and, after supplying only two

small portions of his undertaking, he at length announced, that in accordance with a wish which he had heard Mr. Hunter express, he had burned the manuscripts, which he had taken without leave from the College of Surgeons, and among which were the ten volumes of dissections, and numerous other original papers. The Catalogue, however, is now formed in a manner which, although it cannot compensate for the loss of the other, confers the highest credit on those by whom it has been made.

Hunter is, by the common consent of all his successors, the greatest man that ever practised surgery. Considered merely as a surgeon, and with reference only to the direct improvements which he effected in its practice, he stands inferior to few: his improvement of the operation for aneurism was undoubtedly the most brilliant discovery in surgery of his century. He first described the important disease of inflammation of the veins; he first published lucid views on the venereal disease, and by his work on inflammation improved the modes of practice applicable to nine-tenths of the diseases which fall within the province of the surgeon. But it was less by individual discoveries than by the general tone of scientific investigation which he gave to surgical practice that he made it a science, rather than a mechanical art, and induced men of far higher attainments than those who had before practised it to make it their study.

As an anatomist and physiologist, his museum alone is sufficient to show that he has had no superior; and while his published works confirm this opinion, and exhibit what he knew, they add to the regret that so much more should have been lost.

His surgical works were published under the title of 'John Hunter's Surgical Works, with Life, by Palmer,' 4 vols. 8vo. His life was also written by Sir Everard Home, by Jesse Frost in 1794, and by Joseph Adams in 1816.

HUNTER, WILLIAM, was born in 1718 at Long Calderwood, near Glasgow. He was entered at the University of Glasgow in 1732, and remained there for five years studying for the church; but, while hesitating whether he should pursue that profession, he met with Cullen, who was at that time practising as a surgeon and apothecary at Hamilton. An intimate friendship was soon formed between them, the result of which was that Hunter determined to study medicine, and to practise in partnership with Cullen. Part of the agreement into which they mutually entered was, that each of them should alternately pass a winter at some large medical school, while the other remained in charge of the business in the country. Hunter visited London in 1741, where he resided with Smellie, the celebrated accoucheur, and studied anatomy under Dr. Nicholls, and surgery at St. George's Hospital. Dr. Douglas, to whom he brought a letter of introduction, engaged him soon after his arrival to assist him in completing an anatomical work which he was publishing, and to educate his son. He resided in the family till 1744, when Mr. Sharpe having resigned a lectureship on surgery to a Society of Naval Surgeons, Hunter was elected to fill his place, and at once met with the most marked success. In 1746 he commenced lecturing on anatomy, and in 1747 became a member of the Corporation of Surgeons. But he had always preferred

the practice of midwifery to that of surgery, and, several circumstances coinciding to give a favourable prospect of success, he determined in 1749 to confine himself exclusively to the former branch of the profession. In 1750 he took a Doctor's degree at Glasgow; in 1764 was appointed physician extraordinary to Queen Charlotte; in 1767 he became a Fellow of the Royal Society. His time was now so completely occupied in the practice of his profession, that he was obliged to give up a part of his lectures, and his brother John, Hewson, and Cruickshank were successively his partners. He amassed a large fortune, and died in 1783, with a reputation inferior only to that of his brother, of whom it was not his least honour that he had been the preceptor and first patron.

William Hunter's principal work was the 'Anatomy of the Gravid Uterus,' on which he was engaged for nearly thirty years. It contains thirty-four folio plates, most accurately and beautifully engraved from dissections by himself and his brother, illustrative of the most important subjects in obstetrics. He was also the author of numerous essays in the 'Philosophical Transactions,' and the 'Medical Observations.' He founded a medical school in a private house in Windmill Street, with a museum and dissecting rooms attached to it. His valuable museum he bequeathed to Dr. Baillie, who was to hold it for thirty years, and then to transmit it to the University of Glasgow, to which he left 8000*l.* for its maintenance and increase.

HUNTINGDON. [HUNTINGDONSHIRE.]

HUNTINGDON, SELINA, COUNTESS OF, born 1707, died 1791, was one of the three daughters and co-heirs of Washington Shirley, Earl Ferrers. She married, in 1728, Theophilus Hastings, earl of Huntingdon, who died October 13, 1746. She had many children, four of whom died in youth or early manhood. She became deeply religious, and may be said to have belonged to the Whitfieldian section of Methodism; but she chose to act herself as the founder of a sect. Her followers are distinguished as belonging to 'the Countess of Huntingdon's connection.'

HUNTINGDONSHIRE, an inland county of England, situated between 52° 8' and 52° 36' N. lat., and 0° 3' E. long., and 0° 30' W. long. It is bounded N. and N.W. by Northamptonshire, S.W. by Bedfordshire, and on all other sides by Cambridgeshire. The population in 1868 was 63,683. The area is 229,544 acres, of which, according to the official agricultural statistics, published in 1869, 205,417 are under cultivation—102,179 being devoted to corn; 17,240 to green crops; 12,310 to clover and artificial grasses, and 55,513 to permanent pasture. The number of cattle in the county in 1868 was 23,835; sheep, 167,277; and pigs, 23,130.

Surface, Rivers, &c.—Huntingdonshire has no high hills, but there are two or three elevated tracts. The principal rivers are the Ouse and the Nene, with their respective tributaries. The Ouse enters the county from Bedfordshire, near St. Neots, and, flowing past Huntingdon, enters Cambridgeshire at Earith, after a course of 23 miles in the county or on the borders, all navigable. The Nene has a short course along the northern border before it enters

Cambridgeshire. Whittlesea-Mere, Ramsey-Mere, and Ugg-Mere were large pools or lakes which have been drained and reclaimed. Whittlesea-Mere was the largest English sheet of water apart from the lake district, two miles and a quarter long by one and a half broad, abounding with fish and water-fowl, but since 1851 converted into corn fields and pastures, and occupied with farm buildings. A considerable part of the county is destitute of springs, and is supplied with water from ponds. Formerly it was a deer forest, but at present it is thinly wooded.

Geology, Climate, and Agriculture.—The south-eastern part of the county is occupied by the iron-sand and gault. The rest of the county, excepting the Fens, and perhaps a narrow strip on the western side, is occupied by the Oxford clay.

The climate is similar to that of the contiguous inland counties—mild and healthy, except in the Fens, where, in addition to the humidity, there is a great want of pure water. The soil, in general, is a deep loamy clay or loamy gravel, with good meadow land on the Ouse and Nene. The farms are large, and grain, with beans, rape, and clover, are the chief crops. Cheese, butter, and malt are sent to market. Agriculture generally is in an advanced state, especially in the Fens. The sheep are mostly of the Leicester breed. The hogs are Berkshire or Leicestershire, with various crosses.

Divisions and Towns.—Huntingdonshire is divided into four hundreds and 107 parishes. It is in the diocese of Ely and the Norfolk circuit. The assizes are held at Huntingdon. Two members are returned to Parliament for the county, and one for the borough of Huntingdon. The number of voters on the county register in 1869 was 3637. The following are the chief places:—

Godmanchester is three-quarters of a mile S.E. from Huntingdon. It was for many centuries famed for its very superior husbandry. It has a fine parish church, which was restored a few years since. There are an iron foundry and machine works, and some small manufactures of malt, oil cake, and leather. The parish, which forms part of the parliamentary borough of Huntingdon, contains a population of 2438.

Huntingdon, the chief town of Huntingdonshire, and a municipal and parliamentary borough, is 59 miles from London by the Great Northern, or 77 by the Great Eastern Railway. The town is on a gently rising ground on the north bank of the Ouse, and is connected with Godmanchester by three bridges. Very great improvements have been made in the drainage and sewage during the last few years. The principal street extends about a mile north-west from the bridge over the Ouse, and consists for the most part of respectable houses. St. Mary's Church is of perpendicular character; it was rebuilt in 1620, but had become much mutilated, until it was restored in 1862. All Saints has a fine perpendicular tower, with a good entrance; and another church has recently been erected by Lady Olivia Sparrow, on the site of the old theatre. There are four dissenting chapels, a good town hall, county gaol, hospital, and lunatic asylum, borough gaol, union, an endowed grammar school, and other educational establishments. The trade of the town is considerable, principally in malt, wool, and corn; and there

are manufactures of patent bricks and tiles for draining, two large breweries, and an iron foundry. The market is well supplied with corn and provisions. The municipal borough is governed by a mayor, four aldermen, and twelve councillors; population, 3816. The parliamentary borough formerly returned two members to the House of Commons, but the Reform Bill of 1867 deprived it of one. Population, 6272; number of electors (1869), 901. Oliver Cromwell was born here in 1599, in a house near St. Mary's Church, and was educated at the grammar-school.

Kimbolton is 9 miles S.W. from Huntingdon, and $87\frac{3}{4}$ from London by the Midland Railway. The town is small and unimportant. The church has a tower with a lofty spire, and contains some monuments of the Manchester family. There is an endowed grammar-school, and brewing, malting, tanning, and brick making are carried on to a small extent. Near the town is Kimbolton Castle, the residence of Queen Catherine after her divorce from Henry VIII., and now the seat of the Duke of Manchester. It has recently been renovated and much altered. The park is very extensive and well stocked with deer. The remains of Stonely Priory are also in the vicinity. Population, 1661.

Ramsey is 10 miles N.N.E. from Huntingdon, and $75\frac{1}{4}$ from London by the Great Northern Railway. The town derives its origin from a Benedictine abbey, founded on an island or dry spot in the marshes, called Ram's Ey, i.e., Ram's island, in the reign of Edgar, 969. It consists chiefly of one long street. The church is spacious, and has recently been restored. There are also eight dissenting and a new Roman Catholic chapel, and a large building called the Institution, used for meetings, lectures, &c. Population of the parish, 4500; of the town, 2354.

St. Ives is 5 miles E. by S. from Huntingdon, and $72\frac{1}{4}$ from London by the Great Eastern Railway. The town stands on a slope; the lower part, close on the bank of the Ouse, is liable to be inundated by the floods of that river. Brewing and malting are carried on, but there are no manufactures. Considerable business is done by means of the navigation of the Ouse. A new corn exchange was erected in 1864. In addition to corn, the market is one of the largest in the kingdom for cattle. The church is a light neat building, with some ancient portions, and there are several dissenting chapels. Population, 3395. Cromwell was a resident farmer at St. Ives, and acquired the popular title of Lord of the Fens from some displays of public spirit relative to their improvement.

St. Neots is 8 miles S.S.W. from Huntingdon, and $51\frac{1}{4}$ miles from London by the Great Northern Railway. A Benedictine monastery was early established here, to which the remains, or part of the remains of Neot, a Saxon saint, were transferred from Neotstock in Cornwall. The town is of respectable appearance, and has some good shops. The church is a remarkably fine edifice, and there are some dissenting chapels. The town contains an extensive iron foundry and manufactory of steam engines, gas apparatus, &c., as also some large breweries and steam flour mills. About a mile distant is also a very large paper mill. A new corn exchange was erected in 1863. Population of the parish, 3321.

Stilton is 13 miles N.N.W. from Huntingdon. It was once a market town, but has dwindled into insignificance. The *Stilton* cheese takes its name from this village, but no cheese of that kind is made there. It acquired the name from travellers on the great north road becoming acquainted with its quality at the village inn, the landlord of which obtained it from a relative in Leicestershire, the first and still the chief place of its production. The church of St. James has been thoroughly restored. Brick making is carried on. Population of the parish, 724.

Yaxley is 4 miles from Peterborough and 76 from London. The town is small and irregularly laid out. The church is a fine edifice, built partly in the perpendicular style, intermixed with others of an earlier date. There are dissenting chapels, and an endowed school; a brewery, some malt houses, and an agricultural implement manufactory, and in the vicinity are some market gardens. Population of the parish, 1411.

History and Antiquities.—Huntingdonshire is generally considered to have formed part of the territories of the Iceni, but it must at least have been on the western frontier of that nation, towards the Catyechlani. Upon the subjugation of Britain by the Romans, it was included in the province of Flavia Cesariensis. Two Roman stations are considered to have been in this county. The Roman Ermin Street crossed the county, from S. by E. to N. by W. The Via Devana crossed the county, from near Cambridge to Leicester.

In the earlier part of the Saxon period this county was included in the kingdom of the East Angles. It was subsequently annexed to Mercia. In the later period of the Anglo-Saxon dynasty it constituted an earldom, which continued till 1789, when it was supposed to have become extinct; but a claimant having made out a good title in 1819, it was revived, and still exists, the honour being enjoyed by a branch of the Hastings family.

In the civil wars of Charles I. Huntingdon was plundered in 1645 by the royalists.

Of the churches, Alwalton, Conington, Hartford, and Leighton Bromswold have some portions of Norman architecture. The tower of Chesterton church is a good specimen of early English, with a fine spire. Upton and Wootton churches have also some fine portions of early English architecture.

HUNTLY. [ABERDEENSHIRE.]

HURA, a genus of plants belonging to the natural order *Euphorbiaceæ*. *H. crepitans* is a tree abounding with milky juice. It is a native of the West-Indian Islands, Mexico, and Guiana, where it is called Monkey's Dinner-bell. The fruit of this tree is a depressed woody capsule, about the size of a middling apple, with from twelve to eighteen furrows which separate into as many cocci; each of these separates into two valves, and flies asunder with great elasticity when dry and fully ripe. The noise the fruit makes during this process has obtained for the tree its common name. The juice of the plant is exceedingly acrid, and a small quantity touching the eye will produce blindness. The seeds contain an acrid oil which is a drastic and dangerous cathartic.

HURD, RICHARD, D.D., was born in 1720,

and died bishop of Worcester in 1803. He went to Cambridge at a much earlier age than is now the custom, about fifteen; and his history from that time is that of a scholar, university man, author, and divine. The writings of Bishop Hurd are too many to be particularly named. The most remarkable are his 'Dialogues,' his 'Letters on Romance and Chivalry,' his 'English Commentary on the Epistle of Horace on the Art of Poetry,' and the ingenious Essays published with it, his 'Twelve Discourses on the Prophecies,' his 'Sermons,' and his Life of his friend Bishop Warburton. There is also an octavo volume of the correspondence between Warburton and Hurd, a very pleasing book.

HURDLES are straight flat rectangles of strong wicker work, about six feet long and three feet high, used in military exploits for fencing, barriers, or in the construction of hurdle batteries. In the latter, three of them are fastened at their ends in the form of a triangle, and the central space speedily filled up with earth. A number of these triangles are made to any ground plan, behind which a body of soldiers can intrench themselves in a very short time.

HURDWAR, a famous spot on the Ganges, on the right or west bank of the river, close to its emergence from the mountains, is deemed from its position one of the most sacred sites on the stream, and changes its aspect remarkably by an annual influx of visitors under the twofold influence of religion and trade. At the end of March and the beginning of April a great fair is held; and this being accounted the season most proper for ablutions, there is a prodigious gathering of pilgrims, merchants, and beggars from a wide area of Asia. The ordinary attendance averages from 200,000 to 300,000; but every twelfth year, when a particular festival is held, the number is said to be 2,000,000. The merchandise collected embraces the products of European and Asiatic industry, and also a large number of animals.

HURDY-GURDY. A stringed instrument, the tones of which are produced by the friction of a wheel acting the part of a bow against the strings, which are pressed by the fingers or by keys. It has two strings which always sound bass, like the drones of a bagpipe.

HURON, LAKE. [CANADA.]

HURRAH! an interjection used by the English as a shout of acclamation or applause. It is also used as a war-cry by English soldiers and sailors, at the most exciting times of an engagement.

HURRICANE. In the strict sense of the word a hurricane is a violent rotatory wind, which often sweeps over the Western Atlantic. In China a similar wind is called a 'typhoon,' and in India a 'cyclone.' Other winds of somewhat the same kind, but not so destructive, are called whirlwind, tempest, water-spout, land-spout, sand pillar, tornado, white squall, pampéro, &c. Hurricanes occur most frequently and with the greatest violence in tropical climates, chiefly because, in consequence of the very great heat which there prevails, the rarefaction of the air, and also the condensation of the vapour it contains into rain-drops, take place more suddenly and completely than in more temperate regions. Scientific men to this day are not quite unanimous as to the source and origin of these winds; but after many years of patient and extended investigation they have obtained such infor-

mation as to their form, course, and velocity, that they are enabled to issue directions to mariners by which their former devastating effects may to a great extent be prevented, and, in some instances, the storm itself rendered subservient to the purposes of navigation.

It was for a long time supposed that hurricanes were powerful winds which swept in a straight course along a certain track, which observation had shown to be nearly always used by them; and it was not till the late Mr. Redfield, of New York, and Colonel Sir. W. Reid, of the Royal Engineers, devoted themselves to the study of the subject, and learned those facts respecting the hurricane for which all who traverse the ocean must ever owe them a debt of deep gratitude, that any practical information on the matter could be issued for the benefit of sailors. It is now ascertained beyond a doubt that in hurricanes, tornados, typhoons, and other tempests of a similar character, the wind has a violent movement, in a circular or spiral direction, apparently about a mathematical axis; the latter having, at the same time, a progressive motion on the surface of the land or sea. The diameter of the circle within which the gyration of the wind takes place varies from a few hundred yards to several hundred miles, but the circular motion is, of course, limited to the circumference of the hurricane itself. The progressive motion is no greater than that of the general wind prevailing at the time, which, under circumstances so violent as to admit of the presence of hurricanes, may be somewhat faster than the usual rate. The circular motion is generally upwards of a hundred miles an hour, and is always in one unvarying direction. What formerly appeared to be the shifting of the wind is, in reality, only the progress of the storm, and shows that the ship, island, or whatever it may be, has come within the influence of another quadrant of the hurricane. For it must be evident that the velocity of the wind, in a revolving storm, must be the greatest and least respectively on opposite sides of the axis of rotation, in a diameter which is perpendicular to the path of that axis; for on one side the direction of the revolving current harmonizes with that of the progressive motion of the storm, and on the other it is contrary to it. The direction in which the storm always revolves is from right to left in the northern hemisphere, and from left to right in the southern—in each case contrary to the apparent course of the sun. This being so, it is evident that in a hurricane in the northern hemisphere, the prevailing wind at each of the four great points of the compass will be as follows:—At the northern margin an easterly wind; at the western margin a northerly wind; at the southern margin a westerly wind; and at the eastern margin a southerly wind. The intervening points, of course, are affected by winds modified of these, and the whole arrangement reversed exactly describes a hurricane in the southern hemisphere. With this knowledge the captain of a vessel, by simply observing the direction of a cyclone wind, can easily ascertain his position in the hurricane and how its centre bears from him, and he then only requires to know the way in which the wind will haul, to enable him to make such preparations as may insure the safety of the ship, or even to use the hurricane for the purposes of his voyage.

An acute observer can easily detect the indications of an approaching hurricane. The enormous volumes of vapour which the whirling air within the cyclone, and the external air rushing into it from without, collect and keep together, appear like a dense dark wall resting on the horizon, in the direction from which the hurricane is approaching. The sky also has a lurid and threatening aspect, the atmosphere becomes oppressively hot, and the clouds are tinted with a deep red or dark olive colour. The sun, moon, and stars shine with a pale and sickly light, and as the hurricane approaches, the wind at first moans fitfully and then roars. But as most of these warnings do not allow time for advantage to be taken of them, it is always best to rely upon the barometer, which is quite as certain, and always gives the earliest intimation of the approaching tempest. If the mercury suddenly shifts from high to low, or *vice versa*, and is followed by persistently high and unusual readings, a storm may be expected, and measures taken accordingly. By careful attention to the barometer the ship's position in the hurricane may also be determined, and much danger avoided.

Although so much is now known respecting the laws of storms, we have yet to learn their precise causes, the intervals between their recurrence, and other matters connected with them, before we can consider our knowledge on the subject thoroughly satisfactory.

The best works hitherto published on the subject are—Redfield's *Observations on Storms*; Piddington's *Sailor's Horn Book for the Law of Storms*, and *Conversations about Hurricanes*; Admiral Beaufort's *Remarks on Revolving Storms*; W. R. Birt's *Hurricane Guide*, and his article on Atmospheric Waves in the *Admiralty Manual of Scientific Enquiry*; Admiral Fitzroy's *Weather-Book*; Sir J. Herschel *On Meteorology*, &c.

CYCLONES, TORNADOS, and TYPHOONS, are specially described in separate articles.

HURTOIR, in fortification, the name of a long square piece of timber, which is placed at the head of the platform next to the interior slope of the parapet, for the purpose of preventing the wheels of the gun-carriage rolling down the slope.

HUSBAND. [WIFE.]

HUSBANDRY. In the oldest writings which have been handed down to us, the common operations of husbandry are mentioned, or alluded to, under the Greeks and Romans, in nearly the same terms in which we should describe them now. Considerable progress had been made in the tillage of the ground and in the breeding and rearing of the domestic animals. The practice of fallowing land, to restore its fertility, can be clearly traced to them. The colonies planted by the Greeks and Romans tended to diffuse a knowledge of husbandry among ruder nations.

The land in England consisted originally for the most part of woods, and of extensive pastures, in which sheep and cattle were bred, which constituted the chief wealth. A very small proportion of the soil was cultivated; and, while the population was thin, there was no difficulty in obtaining land which had never before been broken up, and which with little trouble or manuring produced moderate crops of corn. When the husbandmen began to congregate in villages for mutual defence, the best land nearest

to the habitations was cultivated, and the common pastures fed the cattle without much trouble or expense. Manure was seldom made; four times the seed was an average corn crop; and fields were fallowed every second year. Wheat was little cultivated; barley, rye, and oats were the principal produce. Many hogs were fed on acorns and beech-mast in the woods. Bread made of rye, barley, peas, or beans was the food of the labourers who were attached to the soil. The immediate tenants of the land cultivated a portion of the lands which they held for their own use, and let the remainder to smaller tenants, who, although born free, were little above the condition of the labourers, and lived much in the same manner. The live stock was frequently hired from the landlord. Oxen drew the ploughs; horses carried the produce to mill and market; and the implements were of the rudest kind.

The first English author of any note who wrote on husbandry was Sir Antony Fitzherbert, in 1523. The farmer of those days was a hard-working man. Money was seldom seen in his possession. He lived on the produce of his land, and fed his labourers at his own board. Wool was the principal article sold. The sheep were kept on extensive commons at little expense. The great difficulty was to keep them alive in severe winters, and many perished every year.

In the time of Elizabeth some attention began to be paid to the improvement of husbandry; the situation of the farmers appears to have improved; they began to acquire wealth and to increase their domestic comforts.

Cromwell encouraged husbandry; and works on husbandry published by Hartlib, Bligh, and Weston, introduced many improvements in the seventeenth century. From that time to the present day husbandry has improved slowly but regularly. With the increase of population, and a consequent increased demand for the produce of the soil, the cultivation of waste lands, and the granting of long leases to farmers, were resorted to with the best results. Jethro Tull, a gentleman who had a property near Hungerford in Berkshire, introduced a mode of cultivation which was prevalent in Lombardy, and was borrowed from the practice of gardeners, who sow and plant their vegetables in rows with wide intervals. Finding that in rich soils the produce was much increased by stirring the earth round the roots of plants, he formed a theory respecting the food of plants, which he imagined to be extremely attenuated earth. His theory was false; but the introduction of machines to drill the seed in rows, and of others to clean and hoe the intervals, which he principally suggested, has been of infinite use to the improved cultivation of the soil.

The rearing and fattening of cattle on the produce of arable land, which followed the introduction of sainfoin, lucerne, and other artificial grasses, and the cultivation of roots for the same purpose, have made a great change in the old systems. Manure is produced in greater quantity; the land is increased in productive power, and will bear more frequent crops of corn; better implements have been invented to save labour and do the work more completely; and good systems of draining have been introduced. The improvements which have been made in the breeds of cattle and sheep may be considered as entirely modern.

To enumerate the various works which have come

from the press on subjects connected with husbandry would be to give a catalogue of a large library. We can only mention some of the principal authors, such as Lord Kames, Marshall, Arthur Young, Sir John Sinclair, and Dickson. Of these, the most original, perhaps, is the first, but the works of Arthur Young are those which afford the fullest information on the state of British husbandry in the latter part of the eighteenth century, and which did most towards its improvement. The *Farmer's Magazine*, which appeared in 1800, has done much good in disseminating useful practices in husbandry; and later journals, some issued by agricultural societies, such as the Royal and Bath and West of England, have continued to impart similar benefits.

Different systems of husbandry have been prevalent at different times and in different parts of Great Britain.

The first and most inartificial is that which consists in breaking up portions of pasture-land and sowing corn on a slight ploughing, which cannot fail to be productive for some time. Several crops may thus be taken, until the land is so exhausted that the crop no longer repays the seed and labour. To extend this time, experience soon pointed out the crops which succeeded best after each other. Wheat or barley were probably the first crops; afterwards peas, beans, or oats, until the ground, being overrun with weeds, would be left to the renovating effect of time, and a fresh spot would be broken up.

The first improvement on this system is that of infield and outfield. The infield is cultivated more carefully, somewhat like a garden, and all the dung of the cattle is exclusively put upon this part. The outfield is a continuation of the first-mentioned system. The infield consisted of inclosures or open fields near the dwelling, which it was most convenient to cultivate as arable land.

The mode of recruiting lands which have been exhausted by crops or were overrun with weeds, by means of a fallow, seems to have been introduced into England by the Romans, but appears not to have been practised in Scotland till the eighteenth century. The alternate crop and fallow seem to have been later introduced than a fallow after several crops. The triennial system, which consists of a summer fallow, a winter crop, and a spring crop, was probably longer established than any other, and is still the practice in many parts of England.

During the last fifty years many of the old common fields in England have been inclosed and divided by special acts of Parliament; and where such has been the case, a better system of husbandry has generally followed. Clover and turnips are more regularly sown, and, on the light lands, take the place of summer fallow. Clover generally comes after a crop of corn, with which it was sown the preceding year in spring; and as most crops succeed well after clover, wheat was usually chosen for the next crop, as the most profitable. Thus arose the Norfolk (or alternate) system, without any very sudden departure from the old rotations. These changes, and the introduction of beans into the series, gave rise to the improved rotation of turnips, barley, clover, wheat, beans, wheat; after which the land is again cleaned and prepared for turnips with all the manure that can be spared.

As the English systems have taken their origin

chiefly from the infield cultivation, so the Scotch appear to have arisen from that of the outfield. Fallows were unknown; but the sowing of grass seed gave rise to the Scotch convertible system of husbandry, which is gaining ground daily, and bids fair, in remote situations where no manure can be purchased, to be firmly established. The convertible system is not very generally known or adopted in England, and is often confounded with the alternate system. The alternate system interposes a green crop between two white straw crops. On good land the convertible husbandry may consist of three or four years' tillage and three years' grass. Instead of sowing grass seeds after the land is exhausted, it has been found advantageous to accelerate the growth of grass by manuring the crop in which it is sown; and experience has proved that the richer the grass is the more productive are the crops which come after. The grass, instead of being a mere substitute for fallowing and manuring, is made highly profitable by feeding cattle and sheep; and the profit of the years when the land rests, as it were, by being depastured, is often as great as that of the years when it is cropped, and the risk and expense much less.

What renders the improved systems of British husbandry so superior to that of all other nations, is the attention paid to the perfection of the different breeds of domestic animals, especially the horse, the ox, and the sheep. In this respect British husbandry surpasses every other. No expense or trouble is spared to improve the qualities of cattle and sheep.

The great variety of new instruments which are daily invented, and some of which gradually come into use, however expensive they may appear, is another feature in British husbandry; and the letting out of drills and thrashing machines, which are kept for profit by men who have little or no land to cultivate, is a step to that division of labour which has done such wonders in manufacturing industry, and which will no doubt in time do the same in the operations of husbandry. A decided spirit of improvement has also of late years arisen among practical agriculturists, and not the least favourable symptom is, that it is now acknowledged 'much may yet be learned,' and that 'husbandry is still comparatively in its infancy.' The success, at length, of the reaping machine and steam plough is the crowning point of its progress hitherto; and this, conjoined with the extraordinarily developed trade in artificial and manufactured manures, is what indicates most perfectly the energy and enterprise of English agriculturists.

HUSKISSON, WILLIAM, one of the earliest official inaugurators of a liberal commercial policy in this country, was the son of a gentleman-farmer of good family and estate, and born March 11, 1770, at Birch Moreton Court, Worcestershire.

In 1783, when in his fourteenth year, William Huskisson was sent to Paris, and became an enthusiast in the cause of the French revolution. He was present at the taking of the Bastille in 1789, and became a member of one of the French clubs, from which, however, he soon withdrew. In the following year (1790) he became private secretary to Lord Gower (afterwards the Marquis of Stafford), who was then the English ambassador. After the events of the 10th of August, 1792, the English ambassador was recalled, and Mr. Huskisson returned with him to

England. In January, 1793, by desire of Mr. Dundas, he undertook the duties of a small office which had just been created for investigating the claims of French emigrants who were then thronging in crowds to England. Early in 1795 he was appointed under-secretary of state in the department of War and Colonies under Mr. Dundas. Towards the end of 1796 he was brought into Parliament as member for Morpeth. On the retirement of Mr. Pitt, he resigned his official situation. He was unsuccessful in procuring a seat at the general election in 1802, and did not appear again in Parliament until 1804, when he sat for Liskeard. He was secretary of the Treasury under the administration formed by Mr. Pitt in 1804, and, after the death of that minister, was an active member of the opposition. At the general election in 1806 he was re-elected for Liskeard, and after the dissolution of Parliament in 1807 he sat for Harwich, and continued to do so until 1812. From this period until 1823 he represented Chichester, in which neighbourhood he had, in 1801, purchased a small estate. From 1823 until his death he represented Liverpool.

On the retirement of the Whigs from office in 1807, Mr. Huskisson resumed his former post as secretary of the Treasury. He resigned office in 1809, along with Mr. Canning. In August, 1814, he was appointed chief commissioner of Woods and Forests. In 1823 he was made president of the Board of Trade, when he relaxed the navigation laws, the reciprocity acts, &c., under which, by an order in council, foreign ships in matters of importation and exportation were placed on an equality with British ships. Then followed a sweeping reduction of protective duties on foreign merchandise, which, in the case of silk manufactures, brought much odium on the proposer; but the expositions of his policy—clear and convincing—soon brought him converts to the new doctrine. After the death of Mr. Canning, in 1827, Mr. Huskisson held the office of secretary for the Colonies in Lord Goderich's cabinet; and he retained his post when this cabinet was broken up and the duke of Wellington became the head of a new ministry. On the 19th of May, 1829, the debate on the disfranchisement of East Retford took an unexpected turn, and Mr. Huskisson was called upon to redeem a pledge which he had given in a former discussion on the question; and he accordingly voted in favour of the bill and in opposition to his colleagues. After the debate, at 2 A.M., he wrote a note to the duke of Wellington, placing his resignation in his hands. Without any communication with Mr. Huskisson, the duke laid it before the king. The resignation of Mr. Huskisson was followed by that of Lord Palmerston, Mr. Grant, and several others who had belonged to what was called 'Mr. Canning's party.'

At the close of the session of 1830, Mr. Huskisson left London to be present at the opening of the Liverpool and Manchester Railway, on the 15th September. At Parkside, near Newton, Mr. Huskisson, with others, had got out of the carriage, when an alarm was given of the approach of an engine on the other line. Mr. Huskisson attempted to regain his seat, but fell at the moment when the engine passed, and was so much injured that he died the same evening.

Mr. Huskisson married in 1799 the youngest daughter of Admiral Milbanke, but had no family. On retiring from office in 1829 he entered upon the

receipt of one of six pensions of 3000*l.* a year, which the Crown was empowered to grant for long public services.

HUSS, JOHN, was born at Hassinetz, a village of Bohemia, of humble parents, about the year 1370. He studied in the University of Prague. Being ordained priest in 1396, he adopted the opinions of Wycliffe, and gave offence to the archbishop of Prague; but Huss was confessor to Sophia, queen of Bohemia, and was favoured by King Wenceslaus himself, and thus he was able to maintain his ground. In 1408 the heads of the university declared that whoever taught the opinions of Wycliffe should be expelled from that body. Huss identified his cause with that of his Bohemian countrymen, and the consequence was that the German students withdrew from the university and repaired to Leipzig. Huss afterwards became rector of the University of Prague, and inculcated the doctrines of Wycliffe, whose works he caused to be translated into Bohemian. In 1410 the archbishop of Prague ordered them to be publicly burned, and excommunicated those who adhered to the opinions contained in them. He also suspended Huss from his sacerdotal functions, but Huss assembled the people, and preached against the pope, against purgatory, and, above all, against indulgences. He was then summoned by the pope, John XXIII., to appear at Bologna to answer the charges against him, which neglecting to do, he was excommunicated. Huss, however, had a strong party in his favour, and, unwilling to encourage the disorders which arose, he retired to his native village. Some time after, on the death of the archbishop, Huss returned to Prague, and there publicly opposed a papal bull which had been just issued by the court of Rome against Ladislaus, king of Naples. Fresh tumults took place; Huss was cited to appear before the Council of Constance, and he obeyed in 1414, after receiving a safe conduct from the Emperor Sigismund. On arriving at Constance, however, he was arrested. His doctrines were condemned as heretical, and on the 6th of July he was burned. [CONSTANCE, COUNCIL OF.]

HUSSAR. This term was originally applied to the Hungarian horse-soldiers. Every twenty houses or families were ordered by Mathias I. to furnish to his army one horseman; hence from *husz*, twenty, and *ar*, pay, came the word 'hussar.' There are now hussars in every well organized army. In the British there are thirteen regiments of them, composed of light cavalry troopers, dressed in loose jackets and fur cap, and usually armed with a sabre and pistol.

HUSTINGS (Sax. *hustinge*), formerly the principal court of the city of London, in which the lord mayor and aldermen presided. According to Fleta, other towns, as York, Winchester, &c., had courts of the same name. It is now applied to the platform from which members of Parliament address the public at an election.

HUTCHESON, FRANCIS, the most eloquent and influential professor in the Scottish universities in the first half of last century, was born in Ireland, August 8, 1694. His father was a Presbyterian minister. After completing his studies at Glasgow, Hutcheson officiated for some time as minister to a Presbyterian congregation in the north of Ireland. In 1720 he first became known by the publication of

his 'Inquiry into the Original of our Ideas of Beauty and Virtue, &c., with an attempt to introduce a mathematical calculation in subjects of morality.' His essay 'On the Nature and Conduct of the Passions and Affections,' appeared in 1728, and in the following year he was appointed professor of moral philosophy in the University of Glasgow, where he was admitted to the degree of LL.D. His largest work, in 2 vols. 4to., entitled 'System of Moral Philosophy,' did not appear until after his death, which took place at Glasgow in 1747.

HUTCHINSON, JOHN, was born in 1674, at Spennithorne in Yorkshire. He received a good education, and he became steward to the duke of Somerset. Availing himself of the opportunities which his situation afforded him, he made a large and valuable collection of fossils, which, with his own observations, he consigned to the care of Dr. Woodward to digest and publish. This duty Woodward failed to discharge, but bequeathed the task and the collection to the University of Cambridge. In 1724 Hutchinson published the first part of a curious work entitled 'Moses' Principia,' in which he attempted to refute the doctrine of gravitation as taught in the 'Principia' of Newton. In the second part of this work, which appeared in 1727, he continued his attack upon the Newtonian philosophy. From this time to his death he published yearly one or two volumes in further elucidation of his views, which tend to show that the Old Testament contains a complete system of natural history, theology, and religion. They are written in a rambling and uncouth style, but evince a profound and extensive knowledge of the Hebrew scriptures. He died on the 28th of August, 1737.

HUTCHINSONIANS, the denomination of those who followed the philological and exegetical views of John Hutchinson. In their number they reckoned several distinguished divines in England and Scotland, both of the established church and of dissenting communities.

HUTTON, CHARLES, was born at Newcastle-upon-Tyne on the 14th of August, 1737. He manifested at an early period an extraordinary predilection for mathematical studies; and while yet at school he is said to have made considerable progress with little or no aid from his master. Upon the death of his father, which happened before he had completed his eighteenth year, he became teacher in a school at the neighbouring village of Jesmond, and some years afterwards his master, who was a clergyman, having been presented to a living, resigned the school in his favour. In 1760 Hutton married, and removed his establishment to Newcastle, where he met with considerable encouragement. While engaged in tuition, he wrote his first work, entitled 'A Practical Treatise on Arithmetic and Bookkeeping,' which appeared in 1764, and soon passed through several editions. In 1771 he published his 'Treatise on Mensuration,' 4to., London, and the same year, the bridge of Newcastle having been nearly destroyed by a great flood, he drew up a paper upon the best means of securing its future stability, which was afterwards published under the title of 'Principles of Bridges and the Mathematical Demonstration of the Laws of Arches,' Newcastle, 8vo., 1772. In 1773 he became a candidate for the professorship of mathe-

matics at the Royal Military Academy of Woolwich, and obtained the place after a severe competition. Hutton was elected a fellow of the Royal Society, and, upon the accession of Sir John Pringle to the presidency, he was appointed foreign secretary to that body, which office he continued to hold with the greatest credit until he was displaced by Sir Joseph Banks in 1778-79, on the plea that it was requisite the secretary should reside constantly in London. In 1775 the Royal Society instituted a series of experiments on the mountain Schellien in Perthshire, with a view to determine the mean density of the earth. These were conducted principally under the direction of Dr. Maskelyne, and when completed the labour of making the necessary calculations was allotted to Dr. Hutton, who was considered the most competent person for the undertaking. His report is contained in the 'Philosophical Transactions' of the year 1778. In the year 1779 the degree of LL.D. was conferred upon him by the University of Edinburgh. In 1781 he published his 'Tables of the Product and Power of Numbers,' London, 8vo., and in 1785 his 'Mathematical Tables,' containing the common, hyperbolic, and logistic logarithms, with the sines, tangents, &c., both natural and logarithmic, London, 8vo. To these succeeded his 'Tracts on Mathematical and Philosophical Subjects,' in 4to., London, 1786, which were reprinted in 1812, London, 8vo., 3 vols. In 1795 appeared his 'Mathematical and Philosophical Dictionary,' in two large quarto volumes, which for many years supplied works of a similar description with valuable information both in the sciences treated of and in scientific biography.

About this time he undertook, in conjunction with Drs. Pearson and Shaw, the arduous task of abridging the 'Philosophical Transactions.' The work was completed in 1809, in 18 volumes quarto. In 1806 he was attacked by a pulmonary complaint, which a few years after led to his retirement from the academy. Dr. Hutton died January 27, 1823, in the eighty-sixth year of his age.

Besides the works above mentioned, and the papers in the 'Transactions of the Royal Society,' Dr. Hutton was a constant contributor to the *Lady's Diary*, of which periodical he was editor for many years. His remaining works consist of—'Elements of Conic Sections,' 1787, 8vo.; 'A Course of Mathematics, designed for the use of Cadets in the Royal Military Academy,' London, 1798-1801, 3 vols., of which several later editions have appeared; 'Recreations in Mathematics and Natural Philosophy, from the French of Montucla,' London, 1803, 4 vols. 8vo., and some others.

HUTTON, WILLIAM, was born at Derby, of poor parents, 30th September, 1723. At the age of seven he was sent by his father to work in the silk mill at Derby, which occupation he quitted at seventeen, and was bound apprentice to an uncle at Nottingham, who was a stocking-maker. He ran away during his apprenticeship, and wandered as far as Birmingham, but distress compelled him to return to his uncle. In 1746 he taught himself the art of bookbinding, walked to London to purchase a few bookbinders' tools, and in the year 1749 commenced attending Southwell, fourteen miles distant from Nottingham, on the market-day; and here he rented

a shop at twenty shillings a year, and opened it for the sale of books. His object was to save a small sum to enable him to commence business in a large town; and in 1750 he took the lesser half of a small shop in Birmingham, at a rent of one shilling per week, and furnished it with a small supply of books. Five shillings a week covered all his expenses, and at the end of the first year he had saved 20*l*. Fortune continued to smile upon him, and in 1755 he married. In 1791 his property was destroyed during the Church and King Riots at Birmingham that year, but after great difficulty he succeeded in recovering 5390*l*. from the county. He now relinquished business in favour of his son. He had filled successively all the local offices of the town. In 1781 he published his 'History of Birmingham;' and this was followed by other works, of which the principal were—'Journey to London,' 1784; 'The Court of Requests,' 1784; 'The Hundred Court,' 1788; 'History of Derby,' 1790; 'The Roman Wall,' 1801.

Mr. Hutton died 20th September, 1815, a few days before the completion of his ninety-second year. In 1816 his daughter published 'The Life of William Hutton, stationer, of Birmingham, and the History of his Family: written by himself.' An edition of this work was published in 1841, in the series of 'Knight's English Miscellanies.'

HUVEAUNE, River. [BOUCHES-DU-RHONE.]

HUY, a town of Belgium, in the province of, and 17 miles S.W. from Liege, the capital of an arrondissement, and romantically situated on the river Meuse. The name is pronounced *Wé*. The town is fortified, has a line of railway, a college, ironworks and breweries, a citadel, &c. There are also leather, tile, paper, glue, and other factories, and a brisk trade in corn. In 1862 the number of inhabitants was 10,632. Peter the Hermit was interred in the abbey of Neufmoustier, which he founded at Huy on his return from the first crusade.

HUYGENS, CHRISTIAN, was born at the Hague, April 14, 1629. His father, a poet and a mathematician, who died in 1687, at the age of ninety, had been counsellor and secretary to three successive princes of the house of Orange. The subject of this article, his second son, from his boyhood showed an aptitude for mathematical and mechanical studies, and in 1645 he prosecuted them at the University of Leyden. In 1646-48 he studied civil law at Breda. In 1649 he accompanied a count of Nassau to Denmark; and in 1655 he visited France. He then remained in Holland till 1660, when he went again to France, and in 1661 to England, both which voyages he repeated in 1663. In 1665 he was invited to France by Colbert, where he remained from 1666 to 1681, with the exception of two trips to Holland in 1670 and 1675, for health. This consideration prompted his final return to Holland in 1681: he was again in England in 1689, and died at the Hague, June 8, 1695.

Huygens wrote on the quadrature of the hyperbola and on that of the circle. In this last work he gives some new and very close approximations to the quadrature of the circle. He was also engaged in a controversy with James Gregory on this subject.

His 'Horologium,' and 'Horologium Oscillatorium,' appeared in 1673. In the first of these tracts Huygens simply describes the application of the pen-

dulum to the clock, of which improvement he is the inventor. The idea came to him in 1656, and the pendulum employed was the common circular one. In the second he describes the well-known but now disused apparatus by which the geometrically isochronous or cycloidal pendulum was obtained. But this is the least part of the celebrated work before us, which contains four distinct and new discoveries of first-rate importance. The first is that of the cycloid being the curve all whose arcs measured from the lowest point are synchronous. The second is the invention of the involution and evolution of curves, in which the proposition is established that the cycloid is its own evolute. The third is the method of finding the centre of oscillation, being the first successful solution of a dynamical problem, in which connected material points are supposed to act on one another. The fourth is the announcement (without demonstration) of those relations between the centrifugal force and velocity of a body revolving in a circle, which were afterwards proved by Newton in the 'Principia.' It thus appears that Huygens was in complete possession of the solution of the problem of circular motion. Had his mind not been preoccupied by the Cartesian system, it is most probable that he would have gone at least to the extent of deducing Kepler's laws from the assumption of gravitation.

In his optical writings Huygens took up the theory of undulations in opposition to that of emanation, which was adopted by Newton. By this theory he gave a sufficient explanation of the phenomena of reflexion and refraction, and also of that of double refraction, in which Newton could not succeed; that is, he gave an explanation of all the prominent phenomena of optics. The undulatory theory is now almost universally received, and Huygens must be considered as the founder of it; for though Hooke had previously advanced the notion, yet he made no application of it to the explanation of phenomena.

After completing his more profound researches, Huygens spent the evening of his days in the composition of his 'Cosmotheoros (Theory of the Universe), or Conjectures respecting the celestial bodies and their inhabitants.' This interesting work, which, being translated into German and Dutch, passed through two English and two French editions, was written at the age of sixty-five, a short time before he died; and so great was the interest which he felt in its publication, that on the approach of death he earnestly besought his brother to carry his wishes into effect. 'He mentions,' says Sir David Brewster in his 'More Worlds than One,' 'the great pleasure he had derived from the composition of it, and from the communication of his views to his friends. About to enter the world of the future, the philosopher who had added a new planet to our system, and discovered the most magnificent and incomprehensible of its structures, looked forward with a peculiar interest to a solution of the mysteries which it had been the business of his life to contemplate. He was anxious that his fellow-men should derive the same pleasure that he did from viewing the planets and the stars as the seat of intellectual life, and he left them his theory of the universe—a legacy worthy of his name.'

Huygens is distinguished by correctness, penetration, and a freshness of intellect which never left him. Before he was in possession of the formal differential

calculus he was able to supply its place. His power of acquisition lasted to the end of his life. He was near sixty when he read the 'Principia,' and past that age when he began to study the 'Calculus' of Leibnitz. At that time of life persons seldom change old opinions; but Huygens accepted the theory of Newton immediately.

HUYSUM, JAN VAN, was born at Amsterdam, in 1682. The father, a picture-dealer and painter, was the instructor of his son, who soon became celebrated as a flower and fruit painter. His flowers are more beautiful and true to nature than his fruits. He is equally successful in the accessories. He was the first who painted flowers on a light ground. His colours still retain their lustre, and his pictures are still held in the highest estimation. He died in England in 1749. He had three brothers, all painters; one of them, Jacob, came to England, and was chiefly occupied in copying the pictures of his brother Jan, which copies are doubtless reputed to be by the more celebrated brother.

HYACINTH. Few spring flowers are more worthy of cultivation than the hyacinth, whether we regard its varied shades of rich colour or the sweetness of its perfume. The soil and climate of Holland seem to be peculiarly adapted to this plant, for, however well the imported roots may flower in England for the first season, they soon degenerate. It is, however, probable that this arises in some degree from want of skill in the cultivation; for some gardeners have been successful in growing the same roots for several years in succession. The compost used at Haarlem is rotten cow-dung, rotten leaves, and fine sand. The bed into which this compost is to be put must be taken out to the depth of three feet, its bottom made firm, and a few stones thrown into it in order to keep it dry. It must then be raised considerably above the level of the surrounding soil with the compost already prepared. The best season for planting is from October to the beginning of November, and the early sorts planted at this time will begin to show their flowers in the beginning of April.

As hyacinths are planted in autumn, and bloom early in the season, they never require any water, and, as soon as the flowering is over, the more dry the ground can be kept the better it is for the bulbs. When the leaves turn yellow and are withered, which will take place in about a month after the plants have gone out of flower, the bulbs must be carefully taken up and dried.

Hyacinths are frequently grown and flowered in water-glasses. Sometimes before they are put into the glasses they are planted in pots, and when the roots have grown a little they are taken up and washed, and placed in the glasses, or they are placed in the glasses at first. The water must be frequently renewed, or it will soon become fetid and offensive. To prevent their growing long, weak, and pale, so as to flower badly, they should be kept close to a window, where they can be constantly exposed to bright light all day long. In order to secure their pushing out their roots before the leaves lengthen, they should always be kept in the dark for a fortnight or three weeks after they are first placed in the water-glasses, care being taken at that time that the water and the bulbs are not in contact. The moisture that rises

into the air will be sufficient to induce the bulbs to put forth roots; and the total absence of light will prevent the leaves from being stimulated into growth.

HYACINTHINE, a mineral of a brown green colour, transparent, and crystallized in rectangular eight-sided prisms; the fracture imperfectly conchoidal. *Hyacinth* is one of the names given to the brown or yellow crystals of Zircon.

HYÆDES. [TAURUS.]

HYÆNA. In his last subdivision of the digitigrade Carnivora Cuvier includes two groups, the Hyænas and the Cats. It appears to us that the Hyænas constitute a family including the Proteles [AARD-WOLF], and linked by the latter to the Civets. [VIVERRIDÆ.]

The Hyænas are distinguished by having their fore legs longer than their hind legs, by their rough tongue, great and conical molar or rather cutting-and-crushing teeth, projecting eyes, large ears, and a deep and glandular pouch beneath the anus.

Incisors, $\frac{6}{6}$; canines, $\frac{1-1}{1-1}$; molars, $\frac{4-4}{4-4} = 34$.

The false molars, three above and four below, are conical, blunt, and very large. The upper flesh-tooth (carnassière) has a small tubercle within and in front, but the lower one has none, and presents only two trenchant points. The whole of the dental and molar organization, and indeed the whole cranial structure, appears to have been formed with a view to the bringing into the most available action the formidable natural instruments which enable the Hyænas to break the hardest bones.

The Hyænas are ferocious, cowardly, nocturnal animals, and in some countries where they swarm in legions, are the dread of whole districts, in which, however, they in some manner repay the injuries they commit by their services as scavengers. They seldom attack men, unless forced in self-defence, but often carry away children, and destroy sheep, asses, calves, and even cows. The strength of their neck and jaws is prodigious, but their hinder quarters seem to be comparatively feeble, and they run along with a sort of shuffling gait. During the day they conceal themselves in caverns, amidst ruins, and in other obscure retreats. They are skulking, prowling, and, poetically speaking, mysterious beasts. Their wild howlings during the hours of darkness are well calculated to appal even man; and the timid beasts upon which they habitually prey crouch panic-struck, or take to flight. Then it is that these savage and yet cowardly carnivoræ feel themselves confident of success, and prey upon their unresisting victims.

The strength of these animals and their power of dragging away large bodies is strikingly exemplified in Colonel Denham's narrative. At Kouka he relates that the Hyænas, which were everywhere in legions, grew so extremely ravenous, that a good large village, where he sometimes procured a draught of sour milk when on his duck-shooting excursions, had been attacked the night before his last visit, the town absolutely taken by storm, notwithstanding defences nearly six feet high of branches of the prickly tulloh, and two donkeys, whose flesh these animals are, according to our author, particularly fond of, carried off, in spite of the efforts of the people.

The hyænas are confined to Asia and Africa, at

least in the present day, and the following species are known:—

1. The Striped Hyæna (*Hyæna striata*, Zimmerman). Colour variable, generally gray, irregularly barred with brown or blackish brown. A mane runs along the spine from the back of the head, which mane is bristled up when the animal is roused to anger. Locality—India, the mountains of Caucasus, and the Altaic chain, Asiatic Turkey, Syria, Persia, Barbary, Senegal, and Central Africa generally. Susceptible of domestication.

Striped Hyæna (*Hyæna Striata*.)

2. The Spotted Hyæna (*Hyæna crocuta*, Erxleben; *H. Capensis*, Desmarest). This is the Tiger-wolf of the colonists of the Cape.

Spotted Hyæna (*Hyæna crocuta*.)

General colour, gray or grayish brown, irregularly spotted with black. Locality, Southern Africa.

Mr. Steedman, in his 'Wanderings and Adventures in the Interior of Southern Africa,' gives most appalling accounts of the rapacity of the Spotted Hyæna. He states that Mr. Shepstone, in a letter from Mamboland, relates that the nightly attacks of the wolves, as the Hyænas are generally called, have been very destructive amongst the children and youth; for within a few months not fewer than forty instances came to his knowledge wherein that beast had made a most dreadful havoc. 'To show clearly,' says that gentleman, 'the preference of the wolf (Spotted Hyæna) for human flesh, it will be necessary to notice that, when the Mambookies build their houses, which are in form like bee-hives, and tolerably large, often eighteen or twenty feet in diameter, the floor is raised at the higher or back part of the house, until within three or four feet of the front, where it suddenly terminates, leaving an area from thence to

the wall, in which every night the calves are tied, to protect them from the storms or from wild beasts. Now it would be natural to suppose that, should the wolf enter, he would seize the first object for his prey, especially as the natives always lie with the fire at their feet; but, notwithstanding this, the constant practice of this animal has been in every instance to pass by the calves in the area, and even by the fire, and to take the children from under the mother's kaross, and this in such a gentle and cautious manner, that the poor parent has been unconscious of her loss until the cries of her little innocent have reached her from without when a close prisoner in the jaws of the monster.' Mr. Shepstone then particularizes two instances within his own knowledge, one of a boy about ten years of age, and the other of a little girl about eight, who had been carried off by this species, and wretchedly mangled, but recovered by the attention of Mr. Shepstone and his friends. Notwithstanding this ferocity, the Spotted Hyæna has, it is stated, been domiciliated in the houses of the peasantry, 'among whom,' says Mr. Bennet, 'he is preferred to the dog himself for attachment to his master, for general sagacity, and even, it is said, for his qualifications for the chase.'

3. The Villose Hyæna (*Hyæna villosa*, Smith; *H. brunnea*, Thunberg). Colour, a dark brownish gray, with blackish stripes on the limbs. Locality, South Africa. This is the Straand-wolf of the Cape colonists, so called from its frequenting the sea-coasts. The Straand-wolf devours carrion and such dead animal substances, whales for instance, as the sea

Villose Hyæna (*Hyæna villosa*.)

casts up: but when pressed by hunger its habits seem to resemble those of the other species, for it then commits serious depredations on the flocks and herds of the colonists, who hold its incursions in great dread. Mr. Steedman, who states this, says that he saw a very fine specimen, which had been shot by a farmer residing in the vicinity of Blauw-berg, and was informed that it had destroyed three large calves belonging to the farmer. He adds, that it is said to be a remarkably cunning animal, retiring to a considerable distance from the scene of its depredations to elude pursuit, and concealing itself during the daytime in the mountains, or in the thick bush, which extends in large patches throughout the sandy district in which it is usually found.

Fossil Hyænas.—Fossil Hyænas occur abundantly in the third period of the tertiary deposits (Pliocene of Lyell), especially in the ossiferous caverns.

HYÆNA DOG (*Lycæon tricolor*, Brookes; *Canis pictus*, Desmarest; *Hyæna venatica*, Burchell), the Cape Hunting Dog. This daring and ferocious animal, one of the pests of Southern Africa, is a complete dog, or *Canis*, in the form of the skull and the characters of the teeth; it has, however, as in the hyænas, only four toes on the anterior feet, and the same on the feet behind. In figure it is tall, lightly built, but muscular and well proportioned; the limbs are long, the ears large and erect, the jaws powerful, and the teeth strong. Its aspect is wild and fierce, and its disposition treacherous. The fur is close, and of a sandy yellow, irregularly clouded and blotched with black and a little white. The tail is somewhat bushy and of moderate length. The colour is subject to variation. Mr. Burchell, who brought into this country the first specimen, states that it hunts in packs, at night by preference, but frequently in the day. He describes it as swift, fierce, and active, so that only those animals which are gifted with great fleetness can escape from it. It attacks sheep openly and fearlessly; it approaches oxen and horses more cautiously, advancing upon them by stealth, biting off the tails of the oxen, and injuring the horses, especially young colts, so severely that they rarely survive.

HYALÆIDÆ, a family of *Pteropoda*, according to the systems of Lamarck and Cuvier, but belonging to the family *Thecosmata* (order *Aporobranchiata*) of De Blainville. M. Rang, in his 'Tableau Méthodique,' follows De Férussac in making the *Hyalæidæ* a family, and enumerates the following genera as composing it—*Cymbulia*, *Limacina*, *Hyalæa*, *Cleodora*, *Cuvieria*, *Euribia*, and *Psyche*.

Animal furnished with a head, but it is not distinct, with a third natatory membrane smaller and intermediate at the ventral part; mouth situated at the bottom of a cavity formed by the union of the locomotive organs. Shell nearly always present, and very variable in form.

HYALOSIDERITE (Gr. *hyalos*, 'glass,' and *sideros*, 'steel'), a crystallized mineral, of a yellow-brown colour; the surface metallic, and the internal lustre vitreous. Its specific gravity is 2.87. Its component parts consist of silica, lime, alumina, magnesia, soda, protoxide of iron, and potash.

HYBODUS, a genus of fossil fishes placed in the order of *Placoidians* by M. Agassiz, 'Recherches sur les Poissons Fossiles.' The information which M. Agassiz has collected concerning this extinct group of fishes appears to be considerable, yet only in a few instances (from the lias of Lyme Regis and Bristol) has he been able to reconstruct the whole skeleton. The species of *Hybodus* are supposed to amount to twenty-two, and extend from the new red sandstone to the chalk, inclusive.

HYBRID is the term applied by naturalists to the offspring of different species of animals and plants. For the hybridity of animals and birds see the articles **MULE**, **HORSE**, **CANARY BIRD**, &c.

The subject of the hybridization of plants was first investigated by Kölreuter at the end of the eighteenth century. To produce a hybrid plant requires the interference of man, who cuts away the stamens of the flower of which the pistil is to be impregnated with pollen of another species, and carefully prevents all access of pollen except that which he has inserted.

It is very seldom that the result is successful, but when a hybrid is obtained, it is sure to exceed the parent plants in the size and abundance of its fruit, brilliancy of its flowers, and other qualities.

HYDATICA, a genus of fossil plants (probably aquatic) from the coal formation.

HYDATIDS (*Idæria*, a vesicle, from *Idæa*, 'water'). This name has been applied to various bladder-like productions, which are sometimes found in the bodies of men and animals.

The term hydatid comprehends, firstly, several species of entozoa, or parasitic animals, which have a distinct independent vitality; secondly, the simple unattached cysts which are frequently met with; and lastly, what have been called false hydatids, which are vesicular bodies, either entirely or partially connected with the tissues by which they are surrounded.

Hartmann in 1686 first clearly observed that many of the bodies, or cyst-like tumours, called hydatids, were distinct living beings, or parasitic animals. Since his time the subject has been more thoroughly investigated, and there is now no doubt of the animal nature of a large number of hydatids. Pallas arranged all the cystic entozoa, except the common globular hydatid, or *Acephalocyst* (which was only considered as a simple serous cyst before the time of Laennec), under the genus *Tenia*, on account of the similarity of structure between their mouths and those of the tape-worm. Cuvier and other French naturalists gave all these entozoa the generic name of *Hydatid*, but Rudolphi has since shown that they cannot be all placed in one genus, but should be divided into several genera, as *Cysticercus*, *Cœnurus*, and *Echinococcus*, to which may be added *Acephalocystis*. [ENTOZOA.] Several species of *Cysticercus* are enumerated, but the most common are *C. tenuicollis* and *C. cellulosus*. *C. tenuicollis* is met with frequently in the peritoneum and pleura of ruminating animals and pigs. It is often generated in the disease of sheep called the rot, where another entozoon, the *distoma*, or fluke-worm, is met with in the ducts of the liver. The *C. cellulosus* is found generally lodged in the tissues of the muscles between the fibres; it occurs sometimes in man, but more frequently in animals, particularly in the hog, where it causes the disease called measles or leprosy. Of the genus *Cœnurus* the species *C. cerebralis* is found in the brain of sheep, oxen, and other ruminating animals. The hydatids belonging to the genus *Echinococcus* consist of a cyst containing a number of small animals of low organization. The *Acephalocyst* is a simple unattached vesicle, varying in size from a millet-seed to a child's head, filled with pellucid fluid, furnished with no kind of appendix or head, generally associated with numerous others, and contained in a common cyst, which is also filled with fluid.

Hydatids may be developed slowly, and occasion so little inconvenience, that persons in whom they have been discovered after death may not have suspected disease of the organ in which they existed during life. Occasionally they cause so much irritation that suppuration may take place either around or within the common sac, which may burst externally or into a serous or mucous cavity. In either the first or last case the hydatids will be discharged, and the patient may recover; but if the cyst should communicate with

a serous cavity, as the peritoneum or pleura, fatal inflammation will occur.

With respect to the treatment for the prevention or removal of hydatids, it must necessarily, from the obscure notion of the symptoms of the presence of these animals, be of a very uncertain kind.

HYDE, EDWARD, EARL OF CLARENDON, an illustrious statesman and historian, was born on the 18th February, 1608, and was the third son of Henry Hyde, Esq., of Denton, in Wiltshire, a member of a respectable family which for centuries had been settled in Cheshire. He studied at Magdalen College, Oxford, and afterwards in the Middle Temple. His legal studies were not prosecuted at first with great assiduity, and he spent much of his time in the company of gay and dissolute associates. Ill health too, and subsequently a strong attachment to the daughter of Sir George Ayliffe, whom he married in 1629, diverted his attention from his professional pursuits. This lady died six months after their marriage, and in 1632 he married the daughter of Sir Thomas Aylesbury, by whom he had six children, four sons and two daughters.

After his father's death Hyde found himself in possession of a competent fortune. In the spring of 1640 he was returned to Parliament by the constituencies both of Shaftesbury and Wootton Bassett, and made his election to serve for the latter. The borough of Saltash returned him to the Long Parliament, in November, 1640. Up to the time when a bill was passed for preventing the dissolution of Parliament without its authority and consent, Hyde had acted with the moderate portion of the popular party, and indeed had obtained several important reforms; but the democratic tendency of this measure caused him to change his views. He now gave his support to the church, defended the prerogative of the crown, and became one of the three councillors appointed by the king to consult upon and conduct his affairs. These councillors, however, were by no means responsible for all the king's actions. Charles sometimes acted without their consent and knowledge. For instance, in the attempt to seize the five members, his advisers were wholly ignorant of his intention, and were displeased and dejected by the perfidy and rashness of the act.

The queen quitted England in 1642, and Charles left London, not again to reside there until he was a prisoner. Hyde followed him to York, and continued to act as the king's adviser until the civil war broke out. He accepted the chancellorship of the exchequer, and was knighted and sworn a member of the privy council. In 1645 the king thought fit to send the prince of Wales into the West, and to name Hyde one of the councillors to attend upon and direct him. Hyde eventually accompanied the prince in his flight, and landed with him at Jersey, where the prince left him to join the queen in France. Hyde now felt his position to be so dangerous, that he made his will, and wrote letters to be delivered to the king and prince after his death. It might be expected that under such adverse circumstances his spirits would have failed, but constant occupation sustained them; he collected all the materials that he was able, and commenced his 'History of the Rebellion.'

In September, 1648, Hyde rejoined the prince

at the Hague; and here he heard of the execution of the king.

The disposition of the Spanish court towards the youthful Charles II. disposed him to send an embassy to Madrid. Hyde and Cottington were appointed, and during fifteen months negotiations were carried on by them without the establishment of friendly relations. At length the ambassadors received the command of the king of Spain to retire. Hyde quitted Madrid in 1651, and lived at Antwerp with his family until the autumn, when the king returned to Paris. Here he conducted the principal business of the English court, relieving its pecuniary embarrassments as far as his own poverty would permit him, until the Restoration, when, from a powerless and poverty-stricken guardian of an exiled king, he suddenly rose to be the 'first in place, favour, and authority, among the ministers of a monarch, who, while invested by the public with sovereign power, still evinced towards him the deference of a pupil.'

The part that Hyde took in the principal measures that occupied the parliaments after the Restoration may be learned from Lord Clarendon's 'Life,' in Mr. Lister's 'Life of Clarendon,' and Burnet's 'History of his own Times.' We pass to the narration of an event of immediate personal importance to the lord chancellor (the appointment had been conferred on him before the Restoration), which occurred in the autumn of 1660. Anne Hyde, his daughter, had contracted an attachment to the duke of York, the result of which was a secret marriage, celebrated in time to legitimize their first child. This marriage was offensive, not only at court, but also to the chancellor, 'who broke out,' as he tells us, 'into an immoderate passion against the wickedness of his daughter.' The king, assured that there had been no artifice or collusion on the part of Hyde, created him a baron, under the title of Lord Hyde of Hindon. On the occasion of the coronation, which took place in April 1661, the further dignity of the earldom of Clarendon was conferred on him, and he received from the king a gift of 20,000*l*.

Hyde took an active part in the king's marriage with Catherine of Portugal, the negotiation of a loan from the king of France, and the sale of Dunkirk. The opposition of the chancellor to the king's inclination to Catholicism, as well as to other wishes he had formed, diminished his share of royal favour, and gave opportunity to his enemies to cabal against him. But an attempt made by the earl of Bristol to impeach the chancellor for high treason proved ridiculously unsuccessful, and he still continued at the head of affairs. A series of disastrous events, however—the embarrassment of the country at home, and its disgrace abroad—all contributed to diminish his popularity. His influence was successfully undermined, and by the king's command he resigned the great seal on the 30th of August, 1667. The duke of Buckingham was then restored to office.

Seventeen articles of impeachment against Clarendon were then drawn up by a committee of the House of Commons; but the accusation founded upon them was rejected by the Lords, and during the contention that followed the ex-minister quitted the kingdom. A bill for banishing and disenabling Clarendon was passed by the Lords on the 12th of December, and by the Commons on the 18th.

The public life of Clarendon was now at an end; he was permitted by the king of France to reside within his kingdom, and at Moulins he commenced the continuation of his 'Life.' In the spring of 1674 he procured a house at Rouen, which was his last residence. Repeated attacks of gout had enfeebled his constitution, and he expired December 9, 1674, in the sixty-fifth year of his age.

Clarendon's abilities were very great. He was a weighty and dignified speaker, and an able man of business—shrewd, prompt, and laborious; and he combined an earnest desire to uphold the Constitution and promote the welfare of the country, with a sincere regard for the honour of the Crown. As an historian, he displays great insight into character, and considerable powers of description; his style, though generally laboured, often rises into eloquence. Amid prevailing profligacy and corruption he was personally pure and incorrupt. In private life he was blameless, and he was a warm and steady friend; but his temper was hot, harsh, and arrogant, and he was deficient in docility and tact. The principal works of the great historian are, besides his 'History of the Rebellion,' his own 'Life,' 'A Short View of the State of Ireland,' 'A Brief View of the Errors in Hobbes's Leviathan,' and a 'Collection of Tracts.'

HYDE, SIR NICHOLAS, chief-justice of the King's Bench in the reign of Charles I., was the uncle of Chancellor Clarendon, and had the honour of instructing him in the knowledge of law. Sir Nicholas had been employed by the duke of Buckingham in preparing his answer to the articles of impeachment drawn up against him by the House of Commons, and from gratitude for his services on that occasion the duke procured him the appointment of chief-justice in 1626. The most important trial upon which Sir Nicholas Hyde presided was the one in which Sir John Eliot, Hollis, and Valentine were indicted for forcibly holding down in his chair the speaker of the House of Commons while certain resolutions were passed at the violent close of the Parliament of 1627. The court refused to allow the prisoners their Habeas Corpus, and inflicted fines upon them of considerable amount. He died at Hinton Lodge, Hampshire, August 26, 1631, aged fifty-nine. His son, Lawrence Hyde, became principally remarkable for the personal share which he had in furthering the escape of Charles II. after the battle of Worcester. The circumstances are told in a manuscript written by Hyde's cousin, Colonel Gounter. This manuscript is now in the British Museum. He died in 1682.

HYDE, THOMAS, D.D., was born 29th June, 1636, at Billingsley, near Bridgenorth, in Shropshire. He received his first instruction in the Oriental languages from his father, and afterwards studied them under Wheelock, in the University of Cambridge, where he remained about a year. At the age of seventeen he repaired to London, to assist Walton in editing the Polyglott Bible. In 1658 he entered Queen's College, Oxford; in 1659 was appointed under-librarian of the Bodleian; and in 1665 principal librarian. In 1660 he became a prebendary of Salisbury, in 1678 archdeacon of Gloucester, and in 1682 took the degree of D.D. On the death of Pococke, in 1691, Hyde was appointed Laudian professor of Arabic; and not long afterwards Regius professor of Hebrew, and canon of

Christchurch. He resigned the librarianship of the Bodleian in 1701, and died on 18th January, 1703.

Hyde possessed an accurate knowledge of almost all the Asiatic languages which were at that time accessible to European scholars. His most celebrated work is entitled 'Veterum Persarum et Magorum Religionis Historia,' Oxford, 1700; reprinted in 1760.

HYDE PARK, an inclosure of about 390 acres, forming an excellent place for open-air recreation in the heart of the west-end of London. It was formerly known as Hida Manor, and belonged to Westminster Abbey, but became crown property on the dissolution of the monasteries in the reign of Henry VIII. In the year 1550 the French ambassador hunted with the king in Hyde Park, which was then well stocked with game, and kept as a royal inclosure. Nearly the whole of Kensington Gardens were then included in the park; the separation was not made till the time of George II., but they still remain virtually an extension of Hyde Park, and bring the whole space into one area. The Serpentine is a long canal-like piece of water, covering fifty acres, and much used for rowing, bathing, and skating, which was formed by the order of Queen Caroline out of a number of small ponds. Hyde Park has been fashionable for drives and promenades ever since the reign of Charles II. Rotten Row is a road in it devoted exclusively to equestrian exercise, where the fine gravel is always allowed to remain loose. Adjoining to this road the International Exhibition Palace of 1851 was built. The carriage drive on the northern bank of the Serpentine is called *The Ladies' Mile*. Near the Piccadilly entrance, and opposite Apsley House, stands Sir R. Westmacott's bronze statue of Achilles, erected in honour of the late duke of Wellington.

HYDER-ALI-KHAN-BAHADOOR, Sultan of Mysore, a formidable opponent of the British rule in Hindustan, was the son of the chief general of the rajah of Mysore, and born in 1717. Until the age of thirty-three he was comparatively unknown. In 1750 he commanded a contingent against the Maharrattas, fighting in concert with the French. Ascending step by step, in 1759 he reached the rank of commander-in-chief of the rajah of Mysore. After one or two turns of fortune, Hyder not only established himself firmly as prime minister, but pensioned off his master with three lacs of rupees yearly, and became in 1761 the undisputed ruler of Mysore. From this moment he applied diligently and successfully to the increase of his power. His encroachments led to an offensive alliance between the Maharrattas, the Nizam, and the late East India Company; but he found means not only to break up this confederacy, but to engage the Nizam in war against his late friends the British, in 1767. This war was carried on, little to the advantage of the British, for two years, when at last Hyder, by a bold and able stroke, placed himself in a position to prescribe terms of peace, of which the chief conditions were a mutual restitution of conquests, and an alliance in defensive wars. In 1770 the Maharrattas invaded Mysore, and reduced Hyder to great difficulty. He recovered himself, however, and in 1780 burst with a vast army into the Carnatic. He met with continual success, and refused any terms of peace. The war, therefore, continued on the same footing until Madras was

reduced to a frightful state of famine, when the death of Hyder, in November, 1782, relieved the English from danger. His son, Tippoo, concluded peace on the terms of a mutual restitution of conquests.

HYDERABAD, a province of India, Nizam's territory, occupying the whole centre of the Deccan, and entirely surrounded by British territory, between lat. $15^{\circ} 10'$ and $21^{\circ} 46' N.$, long. $74^{\circ} 40'$ and $81^{\circ} 30' E.$ The area is estimated at 95,337 square miles, and the number of inhabitants at 10 millions. The soil, when well manured, bears any kind of crops, without regard to season. Sheep are extensively pastured all over the country. Horned cattle are used as beasts of burden; honey and bees'-wax are plentiful. The chief products are rice, wheat, maize, mustard, castor-oil, sugar-cane, tobacco, cotton, indigo, and fruits, including the vine and melon, with valuable timber. The manufactures are for home use, and comprise cotton and woollen fabrics, and silk—the raw material for the latter, called *tussore*, being gathered in the woods, the produce of a wild worm. Raw and dressed hides, dye-stuffs, gums, and resins, are the chief articles of commerce. [NIZAM'S TERRITORY.] *Hyderabad*, 'Lion's Town,' the capital of the Nizam's dominions, is a walled city, on the river Musi, 389 miles N.N.W. Madras. The population is stated to be 200,000. In the suburb, on the left side of the river, is situated the British residency, a splendid pile of buildings, communicating by a very fine bridge with the city and palace. The public buildings comprise a fine mosque, the Chahâr Minâr ('four minarets') used as a school of arts and sciences, and many other mosques and bazaars. Among the artisans are lapidaries, noted for their skill in cutting precious stones. Silks, with gold embroidery in the weft, turbans, and trinkets, are manufactured. There are several very large tanks in the neighbourhood. (Johnston's *Dictionary of Geography*.)

HYDERABAD, the capital of Scinde, British India, is a town containing 25,000 inhabitants, situate four miles from the east bank of the Indus, in lat. $25^{\circ} 22' N.$, long. $68^{\circ} 28' E.$ It has a fortress and ramparts, flanked by round towers, and is very picturesque. The atmosphere is very dry, and the weather in December and January is pleasant and bracing. Hyderabad is connected with Kurra-chee by a railway, which terminates at Kottree, on the western bank of the Indus. The town is famous for its manufactures of such arms as swords, spears, matchlocks, and shields.

HYDRA, a fabulous monster, to destroy which was one of the twelve labours of Hercules. Its origin is uncertain, some making it the issue of Styx and the Titan Pallas, and others of Echidna and Typhon. It is said to have inhabited the marshes of Lernæa, in Argolis; and to have had many heads, which grew up again as often as they were cut off. The number is variously stated from nine to one hundred. A subtle and deadly poison issued from its numerous mouths.

HYDRA (Gr. *hydor*, 'water'), a genus (and the only one) of the family of the *Hydridae*, of the order Gelatinosi, and class Polypti. Cuvier describes the hydra as among the simplest but most curious of all animal creation in its organization, merely consisting of a small gelatinous horn, provided with filaments

that act as tentacula. Even the microscope discovers nothing in its form but a transparent parenchyma; yet these animals can crawl and swim, and even walk, by attaching the ends of their bodies alternately, like leeches or caterpillars. 'They are usually attached,' says Mr. Dallas, 'to some aquatic plant, and their most favourite station is among the rootlets of the duck-weed, so common in all our ponds. The animal, when extended, consists of a long gelatinous cylinder, attached by one extremity to the sub-aquatic plant, and furnished at the other with very long tentacles, which it stretches about in the water in search of the minute animals on which it feeds.'

The Hydra.

The reproduction of the hydra is by gemmation, or budding, which appears in small tubercles on different parts of the parent animal; and these tubercles separate on arriving at maturity. In warm weather the young hydrae, by the process of gemmation, are produced very rapidly; and, what is still more extraordinary (as Baker observes, in his 'Natural History of the Polype'), 'the young ones themselves often breed others; and those others sometimes push out a third or fourth generation before the first fall off from the parent. Wonderful as these modes of reproduction may appear, they are surpassed by the artificial multiplication of the animal by the division of the body. This was discovered by Tremblay, in his 'History of Polyypes,' in 1774. He says, 'I have opened a polype on my hand, extended it, and cut the simple skin of which it is formed in every direction; I have reduced it to little pieces, and, in a manner, minced it. These little pieces of skin, both those which did and those which did not possess arms, became perfect polyypes.'

These polyypes are extremely voracious, and feed only on living animals. The larvæ of insects, worms, and the minute crustaceous animals which swarm in all waters, constitute their principal food. 'Sometimes two polyypes,' says Mr. Dallas, 'will seize upon the same worm, when a dispute, of course, ensues, which occasionally ends in a very singular manner. If the weaker of the two does not feel inclined to let slip a booty for which he has perhaps been waiting

with extended tentacles for several days, it sometimes happens that each polype swallows the end which has fallen to his share, until at length the worm being all gone, the mouths of the pair come into actual contact. They now find themselves in a position of considerable difficulty, which is sometimes terminated by the breaking of the worm; but if this does not take place, the larger or stronger of the two seizes upon his antagonist, and swallows him, worm and all. After a time the swallowed polype emerges uninjured from his living tomb.'

There are different species of this genus; as the *Corine*, the *Cristatella*, the *Pedicellana*, *Viridis*, *Oligactis*, &c.; but the most curious are the *Vorticellæ*, which abound in stagnant fresh waters, and are arranged as shrubs, plumes, or other agreeable forms; but they are generally too minute for observation by the naked eye.

HYDRA (constellation, *ὕδρως* in Ptolemy), the Water-snake, one of the old constellations. From the time of Arátus downwards it has always been a triple figure: a long snake, represented as trailing upon the ground, bears upon his back a cup (Crater), and nearer to his tail is seated a crow (Corvus). The mythological meaning is altogether unknown.

The great length of this constellation has caused it to be divided into four parts, which are designated as Hydra, Hydra et Crater, Hydra et Corvus, and Hydræ Continuatio. The first contains the head and body up to about ten and a half hours of right ascension, all near to and south of the bright star Regulus; the second contains the cup and the parts of the body adjacent; the third the crow, with the parts of the body adjacent; and the fourth (beginning at about thirteen hours of right ascension) contains the tail.

HYDRACIDS are such acids as contain hydrogen instead of oxygen as the acidifying power: hydrobromic and hydrochloric acids are examples. Their acidity is in general very strongly marked. They contain only one equivalent of hydrogen, and, when acted upon by metallic oxides, they lose their hydrogen by its combining with the oxygen of the oxide, and the results are water and a chloride. All the hydracids are gaseous, and are easily combined with water, forming solutions which possess the well-known and strongly-marked properties of sourness, acting upon carbonates, and reddening vegetable blue colours. They are all artificial products.

HYDRANGEA, a well-known genus of hardy shrubs, of which one species is commonly cultivated for the sake of its beautiful flowers. It is a native of China and Japan, and was originally observed in the gardens of Canton by Loureiro, who took it for a primrose, and called it *Primula mutabilis*. When this plant is hardy enough to survive the winter, it grows to a considerable size, and when covered by a multitude of its very large round heads of rosy flowers, becomes a magnificent object. To grow it in perfection it should be planted in the open ground in rich soil. During winter it should be covered with a mat well stuffed with straw.

HYDRANT, a machine, with suitable valves and a spout, by which water is raised and discharged from the main conduit of an aqueduct.

HYDRAS/PIS (Gr. *hýdor*, 'water,' and *aspis*, 'a shield'), a genus of river tortoises, of the family *Emyda*, in which the sternum is solid and narrow.

HYDRATES. The term hydrate is usually applied to compounds which contain water in definite proportion, which does not impart regularity of form, or, in other words, give crystals with the body with which it so unites. Thus, when water is added to potash, it may form with it either water of solution, water of crystallization, or water which constitutes it an hydrate; and it is observable that, while water of solution has comparatively little affinity for the substance with which it is combined, water of crystallization has more, and water with which the body constitutes an hydrate has the greatest affinity of all.

HYDRAULIC PRESS. [HYDRAULICS.]

HYDRAULICA (Gr. *hydor*, 'water,' and *aulos*, 'a musical pipe'), an organ acted upon by water, and mentioned by ancient writers as producing musical sounds by the compression of water on a large vessel filled with air, by which pressure the air was forced from the vessel into the pipes of the instrument. Its particular construction, however, is not exactly known; but from Athenæus (who attributes the invention to Ctesibus), Plutarch, Hedytus, and others, we learn that it was capable of a great variety of harmony. Claudian speaks of its 'innumera voces,' or numberless tones. But the art of constructing these hydraulic organs appears to have been lost with the destruction of the Roman empire; and the Barbarians attempted in vain to recover it.

HYDRAULICS. This term is applied to the art of constructing machines in which water is employed as a moving power, or by which that fluid is put in motion; and it necessarily includes the principles by which such machines are executed. The art of constructing docks, quays, or any building whose foundations are laid under water, is denominated hydraulic architecture. Of this subject a brief notice will first be offered.

No countries in Europe possess more advantages with respect to naval power than Great Britain and Ireland. The islands and headlands on their coasts form excellent natural ports; and these, where necessary, have been converted into secure harbours by every means which the science of the hydraulic engineer could devise. The breakwaters at Plymouth and Portland, the lighthouses which have been raised in the ocean, and the vast docks at the principal seaport towns, are so many practical examples which render the British Isles a complete school for the study, in detail, of every subject connected with this branch of science.

Hydraulic architecture chiefly now involves the construction of masses of masonry whose foundations are laid in the beds of rivers or in that of the sea, such as the piers of bridges, quays, jetties, and breakwaters; also the formation of artificial harbours and docks for shipping, and locks at the falls on rivers or canals. In all these cases great precautions are requisite to secure the foundations, and give the superstructure sufficient strength to resist the hydrostatical pressure of water which may find its way under or behind, and cause the destruction of the works. The starlings of the old bridges at London and Rochester were examples of the rude methods anciently employed in this country for building in water. Caissons resting on piles driven deep into the ground under the intended work are occasionally employed when the

water is not very deep and the soil good. But no work of magnitude can be considered as secure whose foundations are not laid by the engineer in the bed of the water; for this purpose the part on which the construction is to be raised should, if possible, be laid dry by inclosing it within a coffer-dam, and actually drawing off the water by engines.

From an opinion that the oscillations of the particles of water in waves take place in vertical directions, and because waves become broken in ascending an inclined plane, it has been of late proposed to make the faces of sea-walls quite upright; but since in storms the sea is driven with violence against any object before it, the stability of a wall or breakwater seems to require that its sea-face should have a certain slope. In very deep water, probably the best method of forming an embankment is to allow large blocks of stone, with small fragments intermingled, to descend by gravity into the water, as in the construction of the breakwaters at Plymouth and Portland.

Machinery of some kind for the purpose of raising water in order to drain lakes or marshes appears to have been introduced into Egypt at a very remote period, and the hydraulic machines described by Vitruvius in the tenth book of his 'Architecture' are sufficiently simple to allow the supposition that they had been invented at a very early epoch. That writer mentions a wheel with buckets, which took up water from a reservoir on the ascending side of the wheel, and discharged it on the opposite side, in consequence of the reversion of their position. He, moreover, notices a species of chain-pump, and the spiral machine of Archimedes. All these were intended for the same purposes, and were turned either by the impulse of a stream in which they were placed, or by men walking upon them; that is, probably, on the exterior circumferences of the wheels attached to the axles of the machines. Water-wheels for grinding corn are also described by Vitruvius; and, lastly, the same writer gives a brief and obscure indication of an hydraulic organ for producing modulations of sound.

Since those days hydraulic machinery has been brought to the state in which it now exists by many successive improvements. It may be remarked, however, that on account of the high degree of perfection which, within a few years past, the steam-engine has attained, the employment of hydraulic machines for raising great quantities of water, or as first-motors with respect to extensive works of any kind, has of late considerably diminished. Yet where the circumstances are favourable, as when a supply of water for working the machine can be readily obtained, the latter, from being less expensive in their construction, are still preferred to the former.

The principal hydraulic machines which are in use for domestic or general purposes are the Siphon, the Screw of Archimedes, the various kinds of Pumps, the Hydraulic Press, and Wheels turned by water. For the first two, see **SIPHON** and **SCREW OF ARCHIMEDES**. These and others will be now briefly described.

The common pump is a machine for raising water by the pressure of the atmosphere: it consists of a cylindrical body, or barrel, A B, from the lower part of which a tube, D, descends into the water contained in the well or reservoir. In the interior of the cylin-

der is a movable piston, *F*, surrounded with leather in order that it may be water-tight, yet capable of moving up and down with freedom. The piston is perforated, and the orifice is covered above by a valve which opens upwards: a similar valve, *E*, at the bottom of the cylinder or barrel, covers the upper extremity of the tube which leads to the well.

The piston being raised by means of the handle, the air contained in the tube, *D*, tends by its elasticity to occupy the lower part of the cylinder, which it enters by forcing up the valve, *E*; and its elasticity diminishes in consequence of its occupying a

greater space than before. Hence the air exerts on the surface of the water within the tube, at *D*, less pressure than that which the external air exerts upon the water in the well; and the water consequently rises in the tube to a certain height. The valve, *E*, then falls over the orifice, and the piston being depressed, the air contained between it and the bottom of the cylinder will be condensed; in which state it will force up the valve, *F*, and escape at the top of the pump. The valve, *F*, then falls; and, if the piston be again elevated, the water will rise higher in the tube, *D*, for the same reason as before. The operation of raising and depressing the piston being repeated a few times, the water will at length enter into the cylinder through the valves *E* and *F*; after which it will, at each stroke of the piston, be driven through the spout. Since the column of water in the pump is supported by the pressure of the atmosphere on the water in the well, it is evident [PNEUMATICS] that the greatest height of the piston above the surface of that water can never exceed thirty-three feet.

That which is called a lifting-pump is frequently

similar in construction to the common pump above described; but the lower valve, *E*, is always below the surface of the water in the reservoir, and so also the piston, *F*, when depressed to the bottom of the cylinder or barrel. On raising the piston, the water above it is lifted up, and the pressure of the external atmosphere forces the water of the reservoir to enter into the cylinder through the valve, *E*. Then, by successive depressions and elevations of the piston, the water is at length raised to the top of the pump, and discharged by the spout.

The forcing-pump is one in which the water, when raised in the barrel, is driven through an orifice in its side by the depression of the piston, *F*, which is solid, or without a perforation; it is also, in general, provided with an air-vessel, into which the water is forced, and whence, by the elasticity of the condensed air, it is made to issue through a pipe inserted in the upper extremity.

For raising water from great depths and in large quantities chain-pumps, as they are called, have been frequently employed. In this machine a chain, carrying a number of flat circular pistons, passes round a wheel at the upper, and sometimes also at the lower extremity, each piston, as it goes over the wheels, being in part received in the intervals between the radii. The wheel being put in motion, the pistons descend in a barrel on one side, and enter from below into another on the ascending side, when, pushing the water before them, they raise it into the reservoir, from whence it escapes by a pipe.

Pumps of this kind are frequently fixed in inclined positions; and it is when the inclination of the barrel is about $24\frac{1}{2}$ degrees, the distance of the pistons from one another being equal to their diameter, that the greatest quantity of water is raised.

The hydraulic press was invented by Mr. Bramah, and is a machine of very great power in compressing bodies or lifting weights; or, again, in drawing up trees by the roots, or piles from the beds of rivers. The annexed engraving gives at a glance in section the general details of an hydraulic press. See also Plate 3, fig. 1.

ABCD is an iron cylinder in which works the piston, *EF*. At the bottom of the former is inserted a strong iron piston-rod, *HG*, which passes through the end, *AB*. Let *abcd* be a small tube opening into the part of the vessel *A E F D*, and having a valve at *ab* opening inwards. Let *A E F B* be filled with water, as also a part of the small tube, *abcd*; the pressure of a single pound applied at *h* to the piston-rod, will produce a pressure upon *EF* which will be to the former as the area of the cylinder, *ABCD*, to the area of the tube, *abcd*.

If we suppose the diameter of the cylinder to be ten inches, and that of the piston in the forcing-pump to be one quarter of an inch, then the proportion between the surfaces of the pistons will be that of 1600 to 1; and on the principle of the equal pressure of fluids in every direction, the force with which the piston, *EF*, is raised is to the resistance against the lower surface of that in the forcing-pump in the same proportion.

Water may be made to act as a moving power against wheels by its weight, its momentum, or by both combined. In the first case the wheel is provided with a number of buckets, or troughs, into

which the water is received near the level of the axle of the wheel; the vessels thus filled becoming heavier than those on the other side, the wheel is made to revolve by that excess of weight merely. But if the water fall into the troughs from a channel on a level with the top of the wheel, or at least above the axle, the wheel will revolve both by the weight and by the momentum which the water acquires by its fall. This is called an *overshot* wheel. See Plate 1, fig. 1.

Again, if the lower part of the wheel be placed in a stream of water which is made to act on float-boards fixed on the circumference, the machine has

the name of an *undershot* wheel. (Plate 1, fig. 2.) Lastly, when the wheel is placed in a sort of channel, or *race*, as it is called, which is formed between two projections of masonry below the bed of the upper portion of the stream, and so as to coincide very nearly with the lower quadrant of the wheel's circumference on that side, the water descending from the stream upon float-boards, or troughs, and thus acting both by its momentum and weight, the machine is called a *breast-wheel*. See Plate 1, fig. 3.

Many contrivances have been adopted for enabling the troughs of an overshot wheel to retain, during

their descent, as much as possible of the water which, by entering into them, causes the wheel to revolve; and one of those, which Dr. Robinson considers the most effective, consists in making the side of each trough with three boards parallel to the axle of the wheel: that which is nearest to the *sole* or convex surface of the wheel having its breadth in the direction of the radii and equal to half the interval between the troughs, which is usually about one-fortieth of the circumference of the wheel; and the two other boards making a very obtuse angle with one another, the upper edge of the third being rather above the lowest board in the next higher trough. Mr. Smeaton's inference from his experiments is, that in small works the rim of an overshot wheel should have a velocity of about three feet per second only; but in large works it may be greater. He estimates the greatest quantity of work performed at about two-thirds of the power expended. A *horizontal wheel* differs in no respect from an *undershot*, except in the circumstance of its being placed horizontally, instead of vertically, as represented in Plate 1, fig. 4.

The theory of undershot wheels is very imperfectly known; but it seems, from the experiments of De Parcieux and Bossut, that a sensible advantage is gained by inclining the float-boards to the produced radii of the wheel at an angle of about twenty degrees, each board when at the lowest place having its edge turned towards the upper part of the stream. Such inclination will cause the water to accumulate along the float, and thus act by its weight as well as its pressure; the floats should consequently be rather

broader than the depth of the current of water which they intercept.

If a stream of water, $B A$ (Plate 1, fig. 5), impinge on the float-boards of an undershot wheel, $w H$, and escape from it the very instant after it has made its impact at E, F, C , the quantity of water which actually impinges will be to the whole quantity which passes by it in a given time, as the difference between the velocities of the water and wheel to the absolute velocity of the water.

To observe the effective weight of water in the buckets of any overshot wheel, $A B C$ (Plate 1, fig. 6),

let the buckets, *a b c v d e*, be loaded with water. The equilibrium will be destroyed, because the weight of the water will lie all upon one moiety of the circumference, and cause it to preponderate.

It has been determined by experiment that the effect of the wheel is the greatest when its velocity is about half the velocity of the stream; and it is asserted that the efficacy of an overshot wheel is more than double that of an undershot wheel of equal magnitude.

Mr. Smeaton considered that a breast-wheel unites in some measure the advantages of both the others; for when the water strikes at a certain point below the surface of the stream, and afterwards descends in a circular arc upon the floats, the effect of such a wheel will be the same as that of an overshot wheel when the latter is acted on by a head of water equal to the difference of level between the surface of the reservoir and the point where the wheel is struck, together with that of an undershot wheel which is acted on by a head equal to the difference of level between the point where the wheel is struck and the surface of the water below.

Bossut made various experiments on the motion of water-wheels. The first were with a wheel such as that represented in Plate 2, fig. 1, which had at first 48 float-boards, but which he reduced successively to 24 and 12. The cord, *c o s*, over the pulley, *o*, raises the weight, *p*. From the first experiments it appeared that, the weight raised being the same, the wheel will turn with a greater velocity when the number of paddles are 48 than when they are 24, and greater with 24 than when they are reduced to 12. In another course of experiments, the wheel employed was like that represented in figs. 2 and 4, Plate 2. Here the power was greater with 24 paddles than 12, but it was very little increased by using 48. He also employed such a wheel as is represented in fig. 3. Figs. 5 and 6, Plate 2, represent different views of a machine used by Smeaton in experiments on *undershot* wheels.

Below are enumerated some of the principal hydraulic engines used for raising water. Figs. 2 and 3, Plate 3, represent the screw of Archimedes, which consists either of a pipe wound spirally round a cylinder (fig. 3), or of spiral excavations formed by spiral projections from an internal cylinder (fig. 2). The Germans have a similar machine they call the water-screw, which has its spiral projections detached from the external cylinder in which it revolves.

Hero's Fountain (Plate 4, fig. 2) consists of two vessels, *K L M N* and *O P Q R*, which are close on all sides. A tube, *A B*, passes through the upper vessel without communicating with it, and through the top and almost to the bottom of the under vessel. Another tube, *S T*, is soldered to the top of the under vessel and the bottom of the upper vessel. A third tube, *G F*, is soldered to the top of the upper vessel, and reaches almost to its bottom, and is open at both ends, but with a very small orifice at *G*. Water poured in at *A* descends through *A B*, and compresses the air in *O P Q R*, *K L M N*, into the spaces *O P C* and *K L E*, and is forcibly ejected through *F G*.

Fig. 3, Plate 4, is an irrigating engine designed to raise water to a great height, and is constructed much on the same principle as the fountain above described.

Boswell's Apparatus (Plate 5, fig. 1) is intended to be used with the *Hungarian Machine*, or any similar engine. By comparison of the two figures, we easily distinguish the source, *A*, the basin of water, *I*, to be raised, the receivers, *B* and *C*, the tubes, *b b*, *d d*, *h h*, *n n*, &c., common to both.

Fig. 2, Plate 5, is called the *Ram Siphon*. It is intended to procure a discharge of water from a high point in one continuous stream. The water passes from *A* through the siphon, *A L C R*, shuts a valve at *C*, opens the ascension valve, *E*, and escapes from *M* in a jet.

The *Hydraulic Pendulum* (Plate 5, fig. 3) is designed to produce, by the uniform discharge of a reservoir of water, an alternating or vibrating motion.

Whitehurst's Machine (Plate 6, fig. 1) is employed for the purpose of raising small quantities of water to great heights. *A* is the original reservoir, its upper surface being parallel with the bottom of the reservoir, *K*, to be filled. This apparatus has been greatly improved by Montgolfier in the production of the *Hydraulic Ram* (Plate 6, fig. 2). In this the water is seen to enter the tube at *B*, and ascend through the tube, *G H*, to the receiving reservoir.

The *Hydraulic Clock* is represented on Plate 7.

Hydraulic Machinery has been successfully applied to the production of seamless lead and block tin tubes from solid blocks of these metals, the pressure employed being so great that solid tubes of equal thickness can be made from scraps of lead while in a cold state. An ordinary machine is capable of producing tubes, $\frac{1}{4}$ -inch bore, at the rate of three miles per day; and in the works of Messrs. J. & W. Weems at Johnstone, near Glasgow, is a hydraulic cylinder, 33 inches bore, which was erected by that firm for the manufacture of solid brass tubes by pressure.

Blocks of brass, composed of zinc and copper, were introduced into a steel container on the top of the ram, and submitted to a pressure of from 3000 to 4000 tons, resulting in the separation of the particles of the zinc from the copper, and their combining to form a zinc pipe, while the copper remains in the bottom of the container; thereby separating by pressure the atoms blended together by fusion, and proving that the particles of zinc and copper which enter into the composition of brass are only mechanically arranged, and not chemically combined, as hitherto believed.

Bursting of Hydraulic Cylinders.—The bursting of hydraulic cylinders, when worked up to 2 or $2\frac{1}{2}$ tons pressure per square inch, has long been a constant source of annoyance. Messrs. Weems have made a series of experiments relative to the rupturing action of water as it obtains ingress and egress to the intermolecular spaces of hydrostatic cylinders, distinctly proving that the entrance of the water into the substance of the cylinder is in effect equivalent to slicing off a ring of the metal either inside or outside, and so proportionately reducing its resistance to the internal fluid pressure.

The action of the water may be referred to an annular series of wedges inserted into every possible crevice in the cylinder walls, and driven in to rend the cylinder, so that as each wedge penetrates the metal, the tenacity of the metal is proportionately diminished; and the greater the pressure, the conse-

quently greater distance will the water obtain vent into the metal of the cylinder, when rupture is very easily effected. Under moderate pressures water will always interpenetrate so porous a substance as cast iron, and distribute itself over the surface, at first in the form of very fine particles, which by and by aggregate, and may be seen to run like rain drops in lines extending downwards.

Messrs. Weems, by a recent patent, have overcome this difficulty, and ordinary hydraulic cylinders are thereby rendered considerably stronger within their working limits. The remedy for this evil consists in placing a thin lining of copper, or other material, having great density, and, consequently, high impermeability, between the liquid and the cylinder; that is, a cylindrical lining is fitted closely to the bored interior of the ordinary cylinder. Hydraulic cylinders of this description may be worked at a constant stress of 3.5 tons per square inch. Cylinders, as ordinarily constructed, say of 12 inches bore, and liable to burst at $2\frac{1}{4}$ tons, are bored out to 14 inches bore (giving an extended area) lined with copper, and thus rendered infrangible at a constant pressure of 3 tons per square inch.

HYDRIODIC ACID. [IODINE.]

HYDROBATES. [FULGULINÆ.]

HYDROBORACITE (Gr. *hydor*, 'water,' and *boracite*), a white red-spotted mineral, obtained from silicated peroxide of iron. Its specific gravity is 1.9; and its constituent parts, according to Dr. Thomson, are boracic acid, 49.22; water, 26.33; lime, 13.74; magnesia, 10.71.

[The Greek word *ὑδωρ* (*hydor*, 'water') is of very general application in the form of a prefix to scientific terms, especially in botany, zoology, mineralogy, and chemistry; as *Hydrocotylæ* (water cavities), in botany, a tribe of umbelliferous plants, of which the *Hydrocotyle*, or Pennywort, is the type, and so called from its growing in moist situations; *Hydrocyon* (water-dog), in zoology, a genus of fishes, of the family Salmonide; *Hydrolite* (water-stone), a prismatic crystallized mineral, of snowy whiteness, composed of silica, water, alumina, peroxide of iron, and potash; and 2.05 specific gravity; *Hydrophides*, in zoology, a family of Water-snakes, furnished with poisoned fangs, and belonging to the order Ophides; *Hydrophilidæ* (water-loving), a family of coleopterous insects, of the tribe Lamellicornes; *Hydrosaurus* (water-lizard), a genus of Saurian reptiles, analogous to crocodiles; *Hydroselenates* (water-selenite), in chemistry, a class of salts, formed by the combination of hydroselenic acid with salifiable bases; *Hydrosulphurets*, a class of salts produced by the combination of hydrosulphuric acid with salifiable bases; *Hydrotellurates* (water-tellurium), a kind of salts resulting from the combination of an acid composed of hydrogen and tellurium with salifiable bases.]

HYDROCARBONATE, a mineral obtained from New Jersey, consisting of water, magnesia, and carbonic acid, with traces of silica and peroxide of iron.

HYDROCARBONS, a series of chemical compounds consisting of carbon and hydrogen. They are generally grouped under three leading divisions—1, *Hydrocarbons homologous with Olefant Gas* ($C^4 H^4$); 2, the *Hydrocarbon Radicals of the Alcohols* ($C^4 H^6 O^2$, &c.); 3, *Hydrocarbons homologous with Marsh Gas* ($C^2 H^4$). Under the first class we

have *Methylene* ($C^2 H^2$), *Ethylene* ($C^4 H^4$), *Tritylene* ($C^6 H^6$), *Butylene* or *Oil Gas* ($C^8 H^8$), &c. It will be seen here that the members of this class differ from each other in definite proportions: thus, if we continue the list, the next in the series is *Amylene* ($C^{10} H^{10}$); this is followed by *Hexylene* ($C^{12} H^{12}$), until we come to *Cetylene* ($C^{32} H^{32}$). In the second class we begin with *Methyl* ($C^2 H^3$), then we have *Ethyl* ($C^2 H^5$), *Butyl* ($C^6 H^9$), and so on. In the third class *Marsh Gas*, or *Hydride of Methyl* ($C^2 H^4$), takes the lead; then comes *Ethyl* ($C^4 H^6$), &c. [OILS.]

HYDROCELE (from *ὑδωρ*, 'water,' and *κεφαλή*, 'a tumour') is a collection of watery fluid in the tunica vaginalis testis. The treatment consists, 1st, in the evacuation of the fluid by tapping; and 2nd, in preventing it from accumulating again by exciting such active inflammation of the opposite surfaces of the tunica vaginalis as may produce their adhesion and the obliteration of the cavity.

HYDROCEPHALUS (from *ὑδωρ*, 'water,' and *κεφαλή*, 'head'), water in the head, is a name applied to two diseases nearly peculiar to infancy and childhood, which are distinguished as the acute and the chronic.

Acute Hydrocephalus is a most frequent and fatal disease of the early stages of life. It occurs most commonly between the first and the eighth year. The child is frequently ill for several days before the inflammatory symptoms become evident: it is liable to momentary giddiness while moving quickly, is fretful and nervous, and its rest is disturbed; it loses its appetite, its bowels are costive, and the motions offensive. The eyes become heavy, the face pale, the features devoid of animation, and the child complains of heaviness of the head. The symptoms more surely indicative of the disease are more intense pain in the head, to which the child constantly carries its hand; intolerance of light, sound, and motion; disturbed sleep, with grinding of the teeth, the child frequently waking with a scream; the pulse is slow and irregular. The appetite is lost, the evacuations from the bowels are unhealthy, and vomiting ensues. The abdomen, if previously distended, now falls in, and becomes quite flat. Stupor, interrupted by screams, follows. After these symptoms have continued for some hours or days, there will sometimes be a temporary recovery of sense; but this promising state is soon interrupted by convulsions, complete loss of sight and hearing, and inability to swallow; the extremities become cold, and death follows.

The treatment must vary in the different stages of the disease, but will generally consist in endeavouring to subdue inflammatory action, in removing any causes which may, directly or indirectly, keep up irritation of the brain; and lastly, in the later stages, in supporting the strength of the system.

Chronic Hydrocephalus.—The disease to which this name is applied is correctly denominated *Water in the Head*, being always accompanied with a considerable collection of watery fluid in the cavity of the head, sometimes within the membranes of the brain only, and exterior to the organ itself, but more frequently in the ventricles or cavities of the cerebral hemispheres, which are then distended to the form of a sac. The quantity of fluid is sometimes so great as to cause an increased size of the skull,

amounting to great deformity. The disease generally arises before or very soon after birth; and the cranial bones not being completely ossified at the time of its commencement, they become separated to a distance from each other, and the sutures remain open for a long period. When the disease comes on after birth, its early progress is very insidious.

In the majority of cases medical treatment is quite useless.

HYDROCHARACEÆ, a small natural order of endogenous plants inhabiting ditches, lakes, and rivers, in various parts of the world. None of the species are of any known use, except the *Valisneria alternifolia* of India, which is used for the purpose of conveying water mechanically to sugar in the process of refining it. *Valisneria spiralis* is remarkable for its spiral flower-stalk, which enables it to accommodate itself to the depth of the stream in which it floats, so as to keep its flowers above the water.

HYDROCHLORATES, the name of a genus of salts, formed from the combination of hydrochloric acid and salifiable bases.

HYDROCHLORIC ACID, a colourless gas of a pungent odour, and a strong acid taste, but not so offensive as chlorine itself. It is also known as muriatic acid. It is heavier than air, and has a specific gravity of 1.2474. Exposed to a pressure of forty atmospheres it liquefies. It is incombustible. When it escapes, it produces white fumes by condensing the moisture in the air. It is exceedingly soluble in water, by which it is instantly absorbed. A lump of ice put into a jar of hydrochloric acid gas liquefies quickly, and absorbs the gas. The solution of this acid is of great use in the laboratory. It is prepared by placing three parts of fused chloride of sodium in a retort, and, very gradually, adding five parts of oil of vitriol. The tube by which this liquid is introduced should be bent twice on itself, and have a bulb blown on one portion of the bent part. The retort is connected with a series of Woulfe's bottles: 'in the first a small quantity of water is placed, to detain any impurities; the second bottle may contain four parts of water, and should be immersed in a vessel of cold water, as the condensation of the gas is attended with a great disengagement of heat. On applying a gentle heat to the retort the acid comes over and is condensed. For manufacturing purposes the decomposition is effected in iron cylinders, and only one-half of sulphuric acid described above is used.' A mixture of hydrochloric and nitric acid forms *aqua regia*, so named from having the power to dissolve gold, 'the king of metals.'

HYDROCHÆRUS, Brisson's name for the *Capybara* of Marcgrave, *Cochon d'Eau* of Des Marchais, *Cabiai* of Buffon.

$$\text{Incisors, } \frac{2}{2}; \text{ molars, } \frac{4-4}{4-4} = 20.$$

Molars compound, the posterior teeth the longest, and formed of numerous laminae, which are simple and parallel; the laminae of the anterior molars forked. The other characters are principally found in the four anterior and three posterior toes with which the feet are furnished (all of which are armed with large nails, or rather hoofs, and united by

membranes), the compressed muzzle, the absence of the tail, and twelve teats.

The only species is *Hydrochærus capybara*, *Cavia capybara* of Gmelin, *Sus hydrochæris* of Linnæus.

Capybara (*Hydrochærus capybara*).

Head very large and thick; nose wide; whiskers long and stiff; eyes large; ears rounded and moderate; legs short; hair of the body short and rough, a little like hog's bristles, but finer; colour reddish brown above, yellowish below; size of a rather small two-year-old pig, being probably the largest of existing *Rodents*.

The Capybara is confined entirely to the New World, and found in the neighbourhood of the great rivers in Brazil, Guiana, and Paraguay; some say that it occurs as far north as the Isthmus of Darien.

Marcgrave states that the Capybara lives upon herbs and fruits: that it is a nocturnal animal, swimming across rivers and torrents in search of food, and raising such a horrible clamour as to have terrified the narrator before he knew the cause. He says that they wander in infinite congregations about the banks of the rivers, and, as they are slow of foot, that they save themselves from the hunters by swimming, but that, notwithstanding, large numbers are killed. Pennant, who quotes Muratori, says that it runs slowly, swims and dives remarkably well, and keeps for a long time under water, feeds on fruits and vegetables, is very dexterous in catching fish, which it brings on shore and eats at its ease, sits up and holds its prey with its fore-feet, feeding like an ape, takes its food in the night, and commits great ravages in gardens; keeps in large herds, and makes a horrible noise like the braying of an ass.

Marcgrave speaks of the flesh as tolerably good food, especially if it be roasted. The head, he says, is considered a delicacy. Cuvier also says that the flesh is tender and of a good flavour.

HYDROCORISÆ (Gr. *ὕδωρ* 'water,' and *κόρις* 'a bug'), a tribe of hemipterous or half-winged insects, comprehending the Water-bugs, the Water-scorpions, and the Boatmen. The Hydrocorisæ differ from the Land-bugs (*Geocorisæ*) in having minute antennæ beneath the eyes.

HYDROCOTYLE, a genus of plants belonging to the natural order *Umbelliferae*, and to the sub-order *Orthospermeæ*. Upwards of ninety species of plants have been referred to this genus. *H. vulgaris* is a native of Great Britain and throughout nearly the whole of Europe, in marshy, boggy places, and on the margins of rivulets on a peat soil. This plant is commonly called Pennywort, on account of its leaves lying flat on the ground and having the size

and form of a piece of money. The notion that it produces disease in animals feeding on it is incorrect; but it occurs in damp places, where animals that feed are likely to be attacked with rot and other diseases.

Of the large number of species of this genus few, if any, are used in the arts or medicine, and none of them are sufficiently ornamental to lead to their cultivation.

HYDROCYANIC ACID, or *Prussic Acid*, probably exists ready-formed in several vegetable products, as the leaves of the cherry-laurel and the peach-tree, but it is generally prepared by the action of hydrochloric acid on bi-cyanide of mercury. It is a colourless liquid, with a strong and peculiar odour; its taste is at first cooling and afterwards burning, and it is extremely poisonous. Its specific gravity is 0.6969; it boils at about 80° , becomes solid at about 5° Fahr., and then crystallizes in fibres. As an acid its powers are but feeble. It is so very volatile that, when dropped on paper, the sudden evaporation of a portion of it renders the remainder so cold that it solidifies; and this effect is produced even when the temperature of the atmosphere is nearly 70° . The vapour of hydrocyanic acid has a specific gravity of 0.9363, air being 1. With water and alcohol it combines in all proportions.

Hydrocyanic acid is composed of H^1 , Cyanogen¹. In the state of vapour it consists of equal volumes of those two gases. Neither condensation nor expansion occurs during the combination of the gases which form the acid.

Hydrocyanic acid, especially if it be exposed to light, is subject to spontaneous decomposition. It forms but few salts.

For the medical properties, see **PRUSSIC ACID**.

HYDRODYNAMICS. Under this word are usually comprehended the conditions of equilibrium and of motion in non-elastic fluids, with the resistances which they oppose to bodies moving in them. The subject consists chiefly in investigating by mathematical reasoning, or in showing from observation and experiment, the laws relating to the discharge of fluids through orifices and tubes in vessels or reservoirs, and to their motions in canals or rivers.

Concerning the laws of the motions of fluids as they were known to the ancients, little can be said; the only notice of this branch of science, even in the time of the Roman empire, is contained in the treatise 'De Aquæductibus,' which was composed by Frontinus in the reign of Nerva or Trajan. Even at the end of the sixteenth century, the cause of the ascent of water in pumps was little known. Galileo could give no better reason for it than that it was caused by an attraction which he supposed the piston exercised on the water; and we are indebted to Torricellius for the discovery that the rise of the water is owing to the pressure of the atmosphere on the water in the well in which the pump is immersed. The Marquis Poleni wrote, in 1695, a work entitled 'De Motu Aquæ mixto,' and, in 1718, another concerning the flow of water through orifices and short tubes.

The 'Principia' of Newton contains (lib. ii. sect. 7) a series of propositions concerning the motions of fluids, with investigations of the resistance made by fluids to bodies moving in them; and it may be said

that his theory forms the groundwork of all our knowledge concerning that subject.

Daniel Bernoulli (in 1738) was the first who applied the higher branches of mathematical analysis in the investigation of general equations relating to the problems of hydrodynamics, and the like was done by D'Alembert in 1744. The researches of Euler, La Grange, Laplace, and other continental mathematicians, have since contributed greatly to establish the principles of the science on an analytical basis. The laws of the motions of fluids in canals and rivers were, with every possible precaution to insure accuracy, determined experimentally by the Abbé Bossut in 1771, and by the Chevalier Du Buat in 1786.

In investigating the circumstances attending the discharge of fluids through orifices, it is usual to suppose the fluid to be divided into an infinite number of indefinitely thin laminæ perpendicular to the axis, A B, of the vessel in which it is contained,

and that in the descent of the fluid these laminæ preserve their parallelism till they come near the orifice, when they assume the shape of a funnel, about which the fluid is stagnant. Let the vessel be cylindrical or prismatic, in a vertical position, and have an orifice whose height is C B. Now, if $p'p'q'q'$ be a vertical section through such a lamina, its area perpendicular to the axis being represented by a , and if a' be the area of the orifice C B; also, if g express the force of gravity, h the height A B, and u the velocity of a particle of fluid at the bottom of the orifice; then the relation between the velocity, u , and the height, h , may be found from the equation

$$0 = -\frac{a^2}{2a^2}u^2 - gh + \frac{1}{2}u^2;$$

or considering the orifice as infinitely small, so that a' and the whole first term of the second member vanishes, we have $0 = -gh + \frac{1}{2}u^2$; whence $u = \sqrt{2gh}$.

Now gh expresses the weight of a prism of fluid having unity for the area of its base and whose height is h ; and this is the pressure of the fluid against a small orifice at the bottom of the vessel: but while the height, h , is the same, the pressure is the same whatever be the position or inclination of the orifice;

therefore $\sqrt{2gh}$ will express the velocity at the same depth, whether the orifice be at the bottom or side of the vessel. By the theory of forces this is equal to the velocity acquired by a body in descending by gravity through a height, h , equal to that of the column of fluid, the orifice being infinitely small.

It may be concluded from the above value of u that the velocity of a fluid, spouting upwards through an orifice in a vessel, would cause it to ascend to the level of the upper surface of that in the vessel, if the resistance of the air were abstracted.

It follows also that the velocities of spouting fluids, at different depths below the upper surface, are proportional to the square roots of the depths; that the quantities of fluids discharged in equal times at different depths in the vessel, the latter being constantly full, are to one another in a ratio compounded of the areas of the orifices and the square roots of the depths; and the quantity of water which would be discharged in a given time, t , through an orifice, a , in a vessel kept constantly full at the height h , is expressed by $a't\sqrt{2gh}$.

The velocity u or $\sqrt{2gh}$ expresses the length of a cylinder of water which would flow through the orifice in one second; consequently the time of discharging from a cylindrical or prismatic vessel, the area of whose base is a and whose height is h , a quantity of water equal to that which the vessel will contain, the latter being, however, kept full during all the time that the water is flowing, will be found by making ah equal to $a't\sqrt{2gh}$; whence t (the time required) $= \frac{a}{a'}\sqrt{\frac{h}{2g}}$. The value of g is 32.167 feet or 386 inches; and in these values of u and t it is evident that the areas and height must be of the same denomination as g .

When a vessel is suffered to discharge itself gradually, the velocity of the effluent water diminishes continually; and if the vessel be an upright cylinder or prism, the time (t) in which the vessel would be completely emptied will be obtained, the orifice being small, from the equation $t = \frac{a}{a'}\sqrt{\frac{2h}{g}}$; and com-

paring this with the above value of t , or the time in which an equal quantity would run off, the vessel being kept full, it would be found to be double the latter.

Next, if it were required to determine the quantity of water which would flow through an orifice of finite magnitude when cut in the vertical side of the vessel, which is kept constantly full, it must be observed that the velocity of the effluent fluid at different points in the depth of the orifice varies as the square root of the distance of the point from the upper surface. Now let AB ($=h$) be the vertical height of the water in a vessel in one side of which is formed the orifice whose axis is CB ($=h'$), and let the interval between the parallel lines m, n , represent a vertical section through an indefinitely thin lamina of the effluent water. Then, if the orifice were rectangular, and its breadth were represented by b , the quantity of fluid discharged through the orifice in the time t would be

$$\frac{2}{3} b t \sqrt{2g} \left(h^{\frac{3}{2}} - h'^{\frac{3}{2}} \right);$$

and if the orifice extended from the bottom to the

top of the vessel, having then $h' = 0$, the expression

would be $\frac{2}{3} b t \sqrt{2gh}^{\frac{3}{2}}$. If a rectangular orifice of the same form and magnitude were situated at the bottom B , with its longer side ($=h$) horizontal, the breadth b being very small in this, and also in the preceding case, the quantity discharged in the same time t , the velocity of the effluent water being now equal in every part of the orifice, and being that which is due to the whole height h , would be expressed by $b t \sqrt{2gh}^{\frac{3}{2}}$. The discharge found above is manifestly equal to two-thirds of this quantity.

In the second book of the 'Principia,' Newton shows that many of the particles of water, previously to issuing from an orifice in a vessel, converge towards the orifice in every direction; so that after passing it, they form a stream of diminished breadth, which he called the *vena contracta*. By careful measurement he found the diameter of the latter and that of the orifice to be to one another in the ratio of 21 to 25; and he infers that the velocity in the contracted stream must be to that at the orifice inversely as the squares of those numbers, that is, nearly as $\sqrt{2}$ to 1. Hence, finding from experiment that the velocity in the said stream was equal to that which a body would acquire by falling through the whole height of the fluid column in the vessel, he concludes that the mean velocity in the orifice must be that which is due to half the height of the same column. In practice, when water is made to flow through a small orifice in a thin plate, it is found that the quantity discharged in the time t may always be represented with sufficient accuracy by the expression $0.62 at\sqrt{2hg}$, a being the area of the orifice.

The results of experiments tend to show that, when the height of a head of water in a vessel and the diameter of an orifice in its base or side are given, the discharge of water through a tube inserted in the orifice (its length not exceeding three or four times its diameter) is to that through the simple orifice nearly in the ratio of 12 to 11; and it is observed that, with a given diameter at its farthest extremity, the tube which is formed to coincide as nearly as possible with the natural figure of the *vena contracta* affords the greatest discharge.

A cylindric horizontal tube, $MOPN$ (Plate 1, fig. 1), is attached to a reservoir, $ADCB$. The plug which closes the orifice of the tube, MN , is suddenly removed. The tendency of the particles would first be to describe two parabolas, Mmx , Nny . But mixing with each other they destroy the parabolas, and the fluid has then a constant tendency to contract. The length of the tube, however, causes the water to accumulate, and it issues from the mouth a full stream, though with diminished velocity. But should a tube, mnr , be inserted into a vessel, $ABCD$ (Plate 1, fig. 2), the velocity will be increased nearly in the sub-duplicate ratio of the length of the pipe. And even with a horizontal cylindrical pipe, if proper adjutages be applied, it is possible to increase the expenditure of water in the ratio of 24 to 10, as may be seen in Plate 1, fig. 3. If the plane in which the aperture is pierced be not horizontal, the fluid vein forms a curve in form of a parabola, until the jet, by resistance of the air, loses its shape. This may be exhibited by the apparatus

represented at Plate 1, fig. 4. ABCD is a vessel of iron or copper; PM is a forcing tube, by which the air is condensed in the receiver, which is partly filled with water; QR denotes the tube, and S is a stop-cock between the tube and the receiver. As soon as this cock is turned the compressed air drives the water through the tube.

It is customary to express the slope or inclination of a pipe or canal, when uniform, by the quotient arising from the division of the vertical height of one end above the other by the whole length. But in the case of a reservoir, as AB, having a conduit-pipe DE, let A' be the surface of the water, and E, in the horizontal line FE, be the lower orifice of the pipe. Then, if A'G expresses the height due to the observed velocity at E, GF will be the height necessary to overcome the friction in the pipe, and

GF
DE is considered as the effective slope.

The passage of water through long pipes is greatly retarded by adhesion and friction in the interior, by the resistance experienced where bends take place, and by the disengagement of air. The general rules deduced from the experiments of Abbé Bossut at Mezières, in 1799, are—that the discharges in given times, with pipes of the same length and with the same head of water, are proportional to the squares of the diameters; and when the diameters are equal, the discharges are inversely proportional to the square roots of the lengths of the pipes. A pipe whose length was 600 fathoms, and which was 12 inches in diameter, when the head of water was 12 feet, afforded a discharge amounting to about $\frac{1}{10}$ th; and a pipe of equal diameter, whose length was 2340 fathoms, when the head of water was 20 feet, discharged only $\frac{1}{10}$ th of that which would have been obtained from a simple orifice.

The orifice or pipe through which water is allowed to flow is called *adjutage*; and it may be mentioned here that, by writers on hydrodynamics, short pipes appied as above are denominated *additional pipes*.

Plate 2, fig. 1, illustrates an experiment on the motion of water through long tubes. EFGD is a vertical section of a principal reservoir, containing about 30 cubic feet of water, and communicating by means of a close tube with a secondary reservoir, HKLM, containing about 6 cubic feet, and kept at this height by the supply being regulated from FEDG. To the secondary reservoir was fixed a tin pipe, about 8 or 9 inches in diameter, the other end of which entered into a box of the same metal, with two apertures, A and B, either of which might be opened at pleasure, and to which tin pipes were fixed, capable of being lengthened or shortened at pleasure. Fig. 2, Plate 2, shows a horizontal section of the same reservoir and its appendages, the conduit pipes mentioned above being represented by *at* and *bu*.

In a weir or jetty the water is projected over a waste-board, AB (Plate 2, fig. 3), and the depth of the orifice is measured by the depth of the upper edge of the plank below the level surface of the water.

Experiments were made by Bossut on the theory and construction of jets d'eau. The reservoirs he employed are represented in Plate 2, figs. 4 and 5.

A tin tube, OE, shut or stopped at the extremity E, but opening into the vessel ABCD. The tubes were 6 feet long, the one in fig. 4 being $3\frac{2}{3}$ inches in diameter, and that of fig. 5 only $\frac{3}{4}$ of an inch. In the points F is fixed an adjutage 2 lines in diameter, in G another, 4 lines in diameter; and in N a third, 8 lines in diameter. In fig. 13, at the point K, was fixed a conical tube, KM, and at I a cylindrical tube, IN.

If the water of the river experienced no resistance from the sides and bed, its motion would go on continually accelerating from its source to its mouth, like a solid body falling by the action of gravity; and the consequences would be, that besides the destruction ensuing from the violence of the torrents in the lower lands, the moisture would be drawn from the soils in the upper regions, which would thus become incapable of supporting vegetable and animal life. The adherence of the particles of water to each other, and the friction against the beds, produce a resistance which increases with the velocity of the current, and becomes at length equal to the accelerative force of the descent; and then a uniform motion is established.

But, when a current is in a state of equilibrium, the velocities in different transverse sections of the river may be very unequal, on account of the variations in the areas of those sections, through all of which the same quantity must flow in the same time; since otherwise the equilibrium of the river would not be permanent. It follows that the products of the areas of the sections multiplied by the velocities in each must be equal to each other, and that the velocities in different sections must be inversely proportional to the areas of those sections.

The mean velocity of water in a river may be expressed approximatively by the formula

$$307 \sqrt{\frac{r}{l}},$$

in which *r*, commonly called the mean radius, is in inches the quotient arising from a division of the area of a transverse section of the river by the breadth, the latter being measured on the surface of the bed; and *l* is in inches the extent of a portion of the river, between two points in its length, whose difference of level is one inch. And by experiment it has been found that, if *v'* = the velocity at the surface of the river, *v''* the velocity at the bottom, and *v* the mean velocity as above (all being expressed in inches per second), we shall have

$$v'' = (\sqrt{v' - 1})^2 \text{ and } v = \frac{1}{2}(v' + v'').$$

The mean velocity in any one section may be practically found, tolerably near the truth, by placing in it a rod of wood loaded at one end with a weight sufficient to allow it to float upright in still water. The greater velocity at the upper surface will make the rod incline towards the direction of the stream; and, consequently, when it has acquired a state of equilibrium, it will float in an oblique position; the top of the rod will move slower than the water at the upper surface of the river, and the bottom will move faster than that in the lower part. Hence, the mean velocity of the water in that part of the breadth of the river may be considered as nearly equal to the observed velocity of the rod.

A knowledge of the velocity at the bottom of a

river is of considerable use in enabling the hydraulic engineer to judge of the action of the stream on its bed; and it is evident that, to insure permanency, the accelerative force of the water should be in equilibrium with the tenacity of the channel. It is stated that a velocity of 3 inches per second at the bottom will remove fine potter's clay: a velocity of 6 inches will lift fine sand; that of 12 inches will sweep away small gravel; 24 inches will roll away rounded pebbles; and 3 feet per second will carry along angular stones of the size of an egg. Bossut found that, when the velocity of the stream was just sufficient for lifting the sand, a ridge advanced about 20 feet in a day.

When a body moves in a fluid at rest, its anterior surface being perpendicular to the direction of the motion, if an indefinitely thin lamina of fluid be supposed at every successive instant of time to be displaced, the resistance experienced by the moving surface may be considered equal to the weight of a column of the fluid whose base is the surface pressed, and whose height is that which is due to the velocity; that is to say, the resistance may be supposed to be equal to the pressure which would produce the same velocity at an orifice in the base or side of a vessel. Therefore, if the velocity be represented by v , the

height due to that velocity is equal to $\frac{v^2}{2g}$; then a

representing the area of the moving surface, and D the specific gravity of the fluid, we shall have $\frac{a v^2}{2g} D$

for the pressure against that surface, or the resistance experienced by it, in moving through the fluid. But when the anterior surface of the moving body is oblique to the direction of the motion, the resistance above found must be diminished on account of the inclination. If the number of fluid filaments which act against the surface is constant, the above expression must be multiplied by the square of the sine of the inclination; if variable, by the cube of the sine of inclination, in order to have the effective pressure against the oblique surface.

If a cylindrical body, terminated in front by an equilateral cone, move through a fluid in the direction of its axis, it can easily be shown that, in theory, the resistance experienced is one-fourth, and if the body be terminated in front by a hemisphere, the resistance is one-half of that which would be experienced by the same cylinder if it were terminated in front by a plane perpendicular to its axis.

The circumstances attending the resistances experienced by bodies of various forms and lengths, when caused to move in water, were at a recent period made the subject of numerous experiments, which were carried on by Colonel Beaufoy in the Greenland Docks. Ample details of these valuable experiments were published, and the following are some of the more important results:—

The friction of bodies moving in water is equal to a power of the velocity whose exponent is 1.949.

The pressure sustained at the head-end varies in rather a higher ratio than the square of the velocity, when the velocity is small, and the exponent diminishes with an increase of velocity.

The diminution of pressure on the stern, caused by the fluid not pressing so strongly there when the

body is in motion as when at rest, varies in a lower degree than the square of the velocity; and the exponent diminishes with an increase of velocity.

A globe experiences about one-third of the resistance which is encountered by a cylinder.

A globe cut in halves, and separated by the intervention of a cylinder whose base and length are each equal to a diameter of the former, experiences a diminution of resistance which, compared with that of a complete globe, is nearly equal to one-fifth of the latter.

Bodies whose head-ends are formed with curve lines have great advantage in respect of resistance over those formed with right lines.

The greatest breadth of a moving body should be at a distance from the head extremity equal to two-fifths of the body's length, that the body may move through the water with the least resistance.

Increasing the length of a solid of almost any form by the addition of a cylinder in the middle greatly diminishes the resistance with which it moves, provided the weight in water continues to be the same.

By comparing the resistance of bodies near the surface with those having similar head and stern ends, and which were immersed to the depth of six feet, those at the surface were found to experience more retardation than the others.

The apparatus with which M. Bossut performed his experiments on the percussion of fluids is given on Plate 3, figs. 1 and 2. The beam, $A B$, was three feet six inches; at one extremity was fixed a scale, at the other a plate of copper. The vessel, $x y b z$, contained the water.

HYDROFLUORIC ACID, a compound of fluorine and hydrogen, which was first made known by Scheele. The properties of this acid are, that it is fluid, clear, colourless, and volatile; and when it escapes into the air, which it does at about 60° , it forms with the moisture of it white fumes. Its vapour is extremely pungent and irritating, and it acts strongly on vegetable blues. The specific gravity is 1.06. It acts upon and decomposes glass with great facility, on account of its affinity for the silica which it contains. And hence it has, to a certain though not to a very useful or ornamental extent, been employed to engrave on glass. It is supposed to consist of $H^1 F^1$. When the acid is brought into contact with certain metals it is decomposed, hydrogen gas being evolved, and a metallic fluoride formed. With metallic oxides it forms a fluoride and water.

HYDROGEN, an elementary gas, the lightest of all known bodies. It may be obtained in several modes, but it is usually procured by the decomposition of water, by causing some substance to act upon it which has affinity for its oxygen and none for the hydrogen, so that this element is separated, and assumes the elastic or gaseous state.

The properties of hydrogen gas are, that it is colourless, inodorous, insipid, and it has resisted all attempts which have been made to condense it by the united agency of cold and pressure. 100 cubic inches weigh only 2.15 grains. It refracts light powerfully; by heat it is merely expanded, and suffers no change by the action of electricity, and in electrical decompositions of its compounds it is evolved at the negative pole. This gas extinguishes flame by itself; but

when it meets with a supporter of combustion, as oxygen, it burns readily, and with a continuous but feeble flame, and much heat. When mixed with oxygen, a taper causes immediate and loud explosion, attended with the formation of water by the combination of the gases. It is irrespirable for any length of time.

It is very sparingly soluble in water, 100 cubic inches taking up only about one inch and a half of the gas. Hydrogen, neither in the gaseous state nor in solution, possesses either acid or alkaline properties. When mixed with oxygen gas, and the mixture gradually burned into a small jet, intense heat is generated. When a very small jet is burned, the flickering nature of the flame causes musical sounds when a tube of glass or metal, or even of paper, is held over it. Its atomic number is the foundation of the scale of chemical equivalents, being = 1.

Hydrogen unites with all other elementary gaseous bodies, and forms with them compounds of vast importance and utility: thus with oxygen it forms water; with nitrogen, ammonia; with chlorine, hydrochloric acid; with fluorine, hydrofluoric acid. It combines with bromine to form hydrobromic acid. By its union with several non-metallic solids, as with carbon, iodine, phosphorus, selenium, and sulphur, it forms compounds of very different properties; for an account of these we refer to the substances above-named, except those which it forms with carbon, and which will be now considered under the head of—

Carburets of Hydrogen.

The compounds of carbon and hydrogen may be divided into four classes: the gaseous, liquid, solid, and hypothetical.

Gaseous Carburets.

Carburetted Hydrogen Gas is frequently produced in coal mines, and called Fire-damp. When mixed with air and exposed to flame it occasions dreadful and destructive explosions. It is also generated in stagnant pools by the action of the carbon of decomposing vegetable matter upon water. Carburetted hydrogen gas is colourless, nearly inodorous, and insipid. Water absorbs about 1-60th of its volume. It is fatal to animals, extinguishes flame, but is highly combustible when it meets with a supporter of combustion, and extremely explosive when mixed with it. It burns when a taper is applied to it in contact with the air with a yellow flame, and on account of the carbon which it contains it yields much more light during combustion than pure hydrogen gas. 100 cubic inches weigh very nearly 17·2 grains. Its specific gravity, compared with air, is 0·554. It consists of 4·3 grains of hydrogen gas combined with 12·9 grains of carbon. It is composed of $C^1 H^2$.

Olefiant Gas, or *Bicarburetted Hydrogen*, is prepared by mixing in a retort three volumes of sulphuric acid and one volume of alcohol: when heat is applied decomposition readily takes place. It is a colourless elastic fluid: when pure it has but little odour and is tasteless. It is soluble in about eight times its bulk of water; it is destructive of animal life, is not inflammable, unless a supporter of combustion be present, and then it burns with a dense white light, or, if mixed with air, it explodes with great violence

VOL. VII.

on the contact of flame. 100 cubic inches weigh 30·1 grains. It consists of $C^2 H^2$.

Chloride of Hydrocarbon is a colourless volatile liquid; odour æthereal, taste sweetish, insoluble in water, specific gravity 1·2, that of its vapour 3·4 (air = 1), boiling point about 150° Fahr., burns with a green flame, depositing charcoal, and evolving hydrochloric acid. It is composed of Olef.¹ Chl.¹

Iodine and Olefiant Gas combine to form *Iodide of Hydrocarbon*, or *Hydriodide of Carbon*. It is a solid, colourless, crystalline body, has an aromatic odour, a sweetish taste, and is very dense; neither water nor acid or alkaline solutions act upon it. It consists of Olef.¹ I.¹

Bromine and Olefiant Gas unite to form *Bromide of Hydrocarbon*. It is fluid, colourless, very volatile, has a penetrating æthereal odour, and a very sweet taste. It is heavier than water, very slightly soluble in it; at about 22° Fahr. it becomes solid. It consists of Olef.¹ Br.¹

Liquid Carburets of Hydrogen.

These are very numerous. Those which we shall first describe are all composed of six of carbon and one of hydrogen by weight.

Caoutchen, obtained by subjecting caoutchouc to distillation. It is a colourless fluid, and has a peculiar and æthereal odour; specific gravity, 0·666. It remains liquid at 14° Fahr. and boils at 582°.

Ceten, procured by distilling ethal with anhydrous phosphoric acid. It is a colourless oily liquid, which boils at 527°: the density of its vapour is 7·884.

Eleon, an oily liquid obtained by distilling metaoleic and hydroelaic acids. It boils at 230°, and the density of its vapour is 4·488.

Etherine, a highly volatile liquid. [ETHERINE.]

Eupion. [EUPION.]

Heveen, obtained by the distillation of caoutchouc with sulphuric acid. It is a comparatively dense fluid, its specific gravity being 0·921, and it boils at 579°.

Naphtha.—This is a colourless, limpid, very volatile liquid, with a strong peculiar odour. Its specific gravity is 0·753; it boils at 176° to 212°: the density of its vapour is 2·833: it remains liquid at 0°. It is insoluble in water, but combines in all proportions with alcohol, æther, petroleum, oils, and sulphuric acid. It is very inflammable, and burns with much smoke.

Olein, procured by distilling metaoleic and hydroelaic acids. It is a fluid which boils at 131°, and the density of its vapour is from 2·875 to 3·02.

Benzine. [BENZINE.]

Volatile Oils.—Oil of copaiva, juniper, lemons, black pepper, savin, and turpentine, are all formed of $C^{10} H^8$.

Solid Carburets of Hydrogen.

Hatchetine. [HATCHETINE.]

Ozocerite.—This substance is soft, unctuous, gives a greasy stain to paper; semi-transparent; by transmitted light, of a brownish-yellow colour; by reflected light, yellowish-green and opalescent; odour slightly fatty, which is more perceptible when melted. It fuses at 140° Fahr., attains its greatest fluidity at about 160°, and begins to boil at 250°.

Paraffin, at common temperatures, is a fatty but rather firm solid; it is tasteless, inodorous, and its density is 0·87; at 111° Fahr. it melts into an oily

U

liquid, and evaporates without change; it burns with a pure white flame.

Solid Oil of Roses is crystalline, and becomes liquid at 95° , and boils at 586° to 572° .

Idrialin is solid, insoluble in water, either cold or hot: it imparts to sulphuric acid a beautiful blue tint.

Naphthalin is solid, colourless, and crystalline; when quite pure it is nearly inodorous, but has generally a disagreeable odour; its taste is pungent and somewhat aromatic; it is unctuous to the touch, heavier than water, in which it is insoluble when cold, and only slightly dissolved if hot. It fuses at about 180° to 200° , assumes a crystalline texture on cooling, volatilizes slowly at common temperature, and boils at 410° Fahr.

Chlorine and *Naphthalin* combine to form a solid and a liquid compound. The solid chloride is insoluble in water, and nearly so in alcohol; it melts at 320° , but it may be distilled unchanged. The liquid chloride has a light yellow colour, an oily appearance, is heavier than water, and insoluble in it.

Paranaphthalin is supposed to be a mixture of naphthalin and paraffin.

Caoutchouc. [CAOUTCHOUC.]

Hypothetical Carburets of Hydrogen.

These are such as have never been obtained in a separate state, but which are considered as compounded radicals or bases. *Ethyl* or *Ethule* is one of the number. [ETHYL.] Another, supposed to be the basis of pyroxilic spirit, is called *Methelin*. It is observable that some of these compounds, as naphthalin ethyl, and more especially methylen, act the parts of alkalies, by combining with and saturating acids, and producing crystalline salts with them; and it is a curious circumstance that methylen, which is a theoretic carburet, appears to possess the most extensive power of combination: indeed, it may perhaps be on this very account that it has not yet been isolated.

It is scarcely possible to enumerate all the various compounds of carbon and hydrogen; the progress of organic chemistry is increasing the number every year.

HYDROGRAPHIC OFFICE, an important Government department connected with the Admiralty, where all navy surveys are received; and from them official charts are prepared, and published at a moderate price for the use of naval captains and navigators in general. The art of lithography is here very extensively employed.

HYDROGRAPHY (Gr. *hydor*, 'water,' *graph*, 'to write,') bears the same relation to the sea as geography does to the land. It is a description of the coast-lines, currents, shoals, soundings, islands, and of all things necessary for navigators to know. It includes the surveys of dangerous places, the construction of charts and maps, and the issue of sailing directions for all parts of the globe. In England there is a hydrographical department in connection with the navy, which is constantly employed in making and correcting charts, for which purpose they employ officers in different parts of the world to make observations. In the year 1864 they sold 119,138 charts, and 2248 books of sailing directions, which brought into the exchequer 6420*l*. The total cost of the department in 1864 was 53,807*l*., and in 1865 it was 50,576*l*. The hydrographer is usually a captain in the navy, and receives 800*l*. a

year in addition to half-pay. The cost for drawing and engraving charts is about 6000*l*. annually, and an equal sum for printing and mounting them. The chief expenses, however, are those relating to coast and other surveys, being about 30,000*l*. annually.

HYDROLEACEÆ, a very small and unimportant natural order of monopetalous exogenous plants, allied to *Convolvulaceæ*, with which they were once united. They are weeds inhabiting the East Indies, with alternate glandular or stinging leaves, monopetalous regular flowers, with a gyrate inflorescence, definite stamens, a superior polyspermous two or three celled fruit, and seeds with the embryo lying in the midst of fleshy albumen. In their gyrate inflorescence they correspond with *Boraginaceæ*.

HYDROMETER (*ὕδωρ*, 'water,' and *μέτρον*, a 'measure') is an instrument for determining the relative densities or specific gravities of fluids. By specific gravity is meant the ratio that the weight of any volume of a substance bears to the same volume of water. Thus a cubic foot of alcohol weighs 793 ounces, while the same quantity of water weighs 1000 ounces, so that the specific gravity of alcohol is said to be $\frac{793}{1000}$ or .793. A cubic foot of sulphuric acid weighs 1841 ounces, and has, consequently, a specific gravity of 1.841. The principle of the hydrometer is this:—It is known that when a body is immersed in a fluid it loses as much of its weight as is equal to the weight of that portion of the fluid which it displaces. Hence, if the same body be immersed successively in two different fluids, the portions of weight which it will thereby lose will be directly proportional to the specific gravities of those fluids. The body in this case is supposed to be specifically heavier than the fluid. If it be lighter it will float upon the surface, so that its tendency to descend, or its weight, will then be entirely counteracted by the fluid; from which it appears that, when a body floats upon the surface of a fluid, the weight of the portion of fluid displaced is equal to the entire weight of the body. Now, since the weight of the fluid displaced by a floating body is constant (being always equal to the weight of the body), whatever may be the density of that fluid, it is obvious that if we can determine how much of the body is immersed we may immediately deduce the specific gravity of the fluid; because, when the weight is constant, the specific gravity varies inversely as the bulk.

Upon this principle is constructed the well-known instrument called Sykes' Hydrometer, which is now used in the assessment of the spirit revenue of Great Britain. It consists of a thin brass stem about six inches in length, passing through and soldered to a hollow ball of the same material, and about one inch and a half in diameter. To the inferior extremity of the stem, from which the hollow ball is about one inch distant, a permanent pear-shaped weight is attached; so that, when the instrument is placed in a fluid, the other extremity may float perpendicularly to the surface. There are also ten weights of different magnitudes, by the successive application of which the instrument may be sunk so as to obtain the complete range of specific gravity, from that of pure alcohol to that of distilled water. In fact, so exact and correct is the instrument now made that the addition of even a quart of water to 100 gallons of any spirit may be easily detected; whereas the

most experienced palate, or any other test, will fail to discover the deception even if to the extent of twenty gallons of water to the same quantity of spirits. Although rather difficult to convey a clear idea of the instrument and its use in print, in practice its application is exceedingly simple, when guided by the rules and tables which always accompany it.

The most convenient method of obtaining the specific gravities of fluids is by means of what chemists call a 'thousand-grain bottle.' This is a bottle of a globular form, with a ground glass stopper, so adjusted as to contain exactly 1000 grains of distilled water, at the temperature of 60°, Fahr., and accompanied by a weight, which is an exact counterpoise for the bottle when thus filled. In order to determine the specific gravity of a fluid by this means, it is simply necessary to fill the bottle with that fluid at the temperature of 60°, and place it, together with the adjusted weight, in the opposite scales of a delicate balance; then the number of grains which it will be found necessary to add to one of the scales, in order to produce equilibrium, will be the difference between the specific gravity of the fluid and that of water, taken at 1000. For other forms of Hydrometers see *AREOMETER*.

HYDROMETRIDEÆ, a family of insects belonging to the order *Hemiptera*. This family was established by Dr. Leach, and is thus characterized:—Rostrum with two or three distinct joints; labrum very short; eyes moderate; feet very long, formed for walking on water, with the claws minute, inserted laterally into a fissure on the extremity of the terminal joint of the tarsus.

The genera *Hydrometra*, *Gerris*, and *Velia* of Latreille, belong to this family. Those species which have cetaceous antennæ, the head prolonged into a snout and receiving the rostrum beneath, belong to the first of these three genera, of which the *Hydrometra stagnorum* will serve as an illustration.

HYDROMYS. [*MURIDÆ*.]

HYDROPATHY, or more correctly *HYDROTHERAPEIA*, is the art of treating diseases by the application of water in various ways and at varied temperatures. It may truthfully be said that the employment of water as a remedial agent dates from the most ancient times in which we have any authentic records of medical treatment. Hippocrates frequently alludes to the application of both cold and hot baths, as does Celsus, and Galen also, though less frequently: for with him began the purely pharmaceutical treatment of disease which still obtains in the ordinary practice, although with diminished faith in its efficacy by the most enlightened of its practisers. But the special art which under the name of *Hydrotherapeia*, or *Water Cure*, has during the last thirty years become so well known and so extensively practised, dates from the time when a Silesian small farmer, named Priessnitz, first conceived the plan of using water alone for the cure of disease. This date corresponds, as nearly as can be ascertained, with the year 1827. As is so often the case in similar instances, the discovery of the art in question was the result of an accident, improved by the sagacity of a singularly observing man. A little child of Priessnitz had injured the ribs on one side of the chest; the surrounding parts

were hot and throbbing, and the child was restless. After the infriktion of various ointments and liniments to no purpose, save to exasperate the irritation, Priessnitz, feeling the skin to be very hot over the bruised spot, concluded that something cool would be at least pleasant to have. He therefore applied a thick linen cloth wrung out of cold water over the part, and in order to prevent the too speedy drying of it, covered it with a dry cloth. He observed that, pleasant to the sensation as the cold wet cloth was, the really soothing effect was produced when the reaction of the skin upon the cold had taken place, and warmth had been established. He also further remarked, that if this warmth accumulated beyond a certain point, the skin, instead of being soothed, became irritated, and the bruised part, as well as the patient altogether, became more uncomfortable and restless. Thereupon he refreshed the wet cloth with cold water, and noted the rapidity or slowness of its heating, measuring thereby the amount of irritation to be subdued. Under this simple process his child's bruised ribs speedily recovered. Some time afterwards the same child fell under a severe attack of ordinary fever. Feeling the skin all over the body to be in the same hot and uncomfortable state in which the local bruise had been, he reasoned—'If a cold wet cloth covered with a dry one could soothe the hot skin on the ribs, why should not a cold wet cloth all over the body soothe the skin all over the body?' and he proceeded at once to envelop his fevered child's entire frame in a sheet wrung out of cold water. Such is the history of the first step taken in the direction of modern hydrotherapeia; and this envelopment, or 'packing,' as it is technically called, was the most daring, the most original, and as experience has long proved, the most extensively useful of all the processes of the remedial art in question. Having stated that Priessnitz' treatment of his child on this occasion was eminently successful, and that, as a consequence, he was requested by his neighbours to treat all kinds of febrile complaints in their families, it may be readily imagined that the same observation and ingenuity which had enabled him to go thus far, pointed out to him numerous modifications in the mode of applying water, in the course of the multiplied cases which were brought to him from the gradually increasing circle of the country about him; and in this manner he came to devise and apply most of the processes which constitute the means of water cure. From his near and distant neighbours his fame spread year after year to the great towns, and finally to the capitals of Germany; and in the year 1840 the small town of Gräfenberg, on the slope of the Silesian hills, and the large house which he had by this time erected in it for the reception of patients, was crowded by 300 to 500 persons from all parts of Germany, from Russia and Poland, from Italy, and from England, all seeking treatment for some malady or other from the gifted Silesian farmer. Meantime that farmer was totally unacquainted with anatomy, physiology, chemistry, and all the cognate knowledge, the possession of which constitutes the educated physician. He may have known on which side of the trunk the liver is; but if he did, that was as much as he knew about that organ which he was so constantly called upon to treat. And so of all the

other great organs of the body. He never felt the pulse, rarely looked at the tongue, and made no inquiries about the secretions. He judged of the patient's condition almost entirely by an accurate examination of the skin, which he would try with moist and dry friction. He also was much guided by the expression of the face, and by the patient's power of sleeping and of walking. Of the power and quality of digestion he took no measure, and was singularly careless, not to say reckless, regarding the quality of articles of food; and of their quantity also, for he rather desired his patients to eat as much as they could of the coarse and ill-cooked food which he gave them, remarking often that 'people never could get well without strength,' which strength was to be obtained from the food aforesaid. This last remark gives us the cue to the medical theory of this singular man and close observer; and he seems to have formed it at an early period of his healing career. He remarked that his remedies only placed the body in the best position for exercising the power of *recovering itself*; and that this power was based upon the quantity and quality of the blood which nourished the tissues, which were to make the effort at self-restoration. Practitioners of medicine of the largest experience and the most accurate observation have recorded the same conclusion as the result of their experience, although the larger mass of less enlightened practitioners still believe that their drug remedies have a direct, specific, antagonistic agency in the eradication of morbid conditions. Priessnitz came to the sound conclusion; but whilst he considered that quantity of food was the high road to health and strength, through the formation of a large quantity of blood, he failed to appreciate those aberrations in the circulation of the blood which form so large a portion of the list of human maladies. Accordingly, we shall not be surprised to hear, that in congestions of the brain, of the lungs, and of the womb, he frequently committed errors leading, in some recorded instances, to most disastrous results. Yet these were the exceptions to the thronged list of cases which he cured, by calling forth the self-restorative powers of the body through the agency of his own hydrotherapeutic inventions. Many educated medical men visited Gräfenberg for the purpose of witnessing the operation of the strange treatment, so opposed to all received opinions. Priessnitz never could tolerate these interlopers, who cross-questioned him as if he had been brought up in the schools instead of the fields, and who, not content with the facts before them, desired to know *why* means so contrary to their own succeeded; whereas, if their own physiological education had been sound and enlarged, they should have been able themselves to explain the curative phenomena around them. Neither to them nor to his patients did Priessnitz address many words—a pointed sign of his wisdom under the circumstances; and although never unkind or uncivil to any one, his silence and his manners showed his indifference to the pleasing of any one for the sake of retaining them and their purses at his disposal.

The fame of Priessnitz and of his treatment had been common in a large part of Germany and Switzerland for years before it reached England. This it did in the first instance in the shape of a work by

Mr. Claridge, who had been a patient at Gräfenberg, had been cured, and resolved in the enthusiasm of gratitude to make known to his countrymen the wondrous remedies and cures which he had seen administered and made. This was in 1841. In the following year Dr. Wilson published a pamphlet on the subject, but rather of a controversial than descriptive kind. At the same time he commenced to practise hydrotherapeia at Malvern, to be followed after three months by Dr. Gully. In 1846 this last-named gentleman published an elaborate and full work on the subject, entitled 'The Water Cure in Chronic Disease,' which has remained the textbook which is most referred to. In the same year Dr. Edward Johnson gave forth a work on water treatment, in which he endeavours to account, on chemical and other physical grounds, how it is that the water acts in its varied modes of application. Subsequently he published a large work on the 'Domestic Use of Water Treatment,' in which, however, he mixes drug medication with the hydrotherapeutic. The last work which deserves to be mentioned here, is a second one by Dr. Gully, entitled 'The Water Cure in Acute Disease,' being a pendant to his previous work on 'Chronic Disease,' as above named. No other works on the subject have been sent forth which are worthy to be mentioned. All the others are written not so much to elucidate and promulgate the art, as to advertize the abode of the writer, and recommend the sanatorium which he keeps for its practice. In spite, however, of this defect in the practitioners of water treatment, and in spite of the bigoted opposition to it which has for many years been exhibited by those who do not practise it, there is no doubt that it is steadily making its way into ordinary practice as a recognized and powerful mode of treating diseases, both of a chronic and acute character. In some of the London hospitals and at the Edinburgh Royal Infirmary, several of the processes of hydrotherapeia are commonly employed, especially in febrile complaints; and there is every prospect that ere many years are past it will constitute the almost sole treatment in our fever hospitals. There are at the present time in the United Kingdom upwards of twenty establishments for the cure of chiefly chronic diseases by water. In the United States of America, also, large establishments exist, but they are not numerous; nor are any of them, so far as it appears, purely houses for the reception of patients, including as they do the hotel for the sound man as well as the house of health for the ailing man. This arrangement obtains far too frequently in England also, and is, as Dr. Gully has well observed in his last work, a great cause of the slowness with which the ancient practitioners have admitted only part of it into their ordinary practice, and of the obstinacy with which the great majority of them refuse even to investigate it. Meanwhile this obstinacy proves no obstacle to the expression of a very decided opinion against it when an opinion is desired; for it is a rule of the human mind to be most positive in opinion when it is least grounded in the knowledge of the subject.

Such is briefly the history of the hydrotherapeutic art of healing up to the present day; and it exhibits the extreme difficulty with which even the most open and obvious facts are admitted when they differ

widely from other facts which have been long admitted and acted upon.

We pass now to the description of the particular modes of applying water so as to constitute hydrotherapeutic treatment. These modes or processes, as they are often called, are divisible in a general way into those which have a soothing and those which have a tonic or exciting operation on the body. In the former are the packing or envelopment, general or partial, in wet linen sheets or cloths; fomentation, hot or cold; compresses; tepid sitz baths of any duration, or cold sitz baths of long duration; general warm, but not hot, baths. In the latter are the general cold bath; cold pail douches; very hot general baths; partial spongings with cold water; short cold sitz baths of still and of running water; shower baths, vertical and lateral; falling douches of different calibres; spinal washings; cold foot baths; plunge baths; dripping sheets and dripping towels applied with friction. This is not a very long list; nevertheless, by the skilful adaptation of temperature and duration of application, results of the most varied kind may be obtained—far more numerous and varied, so its advocates state, than can be obtained from the two dozen medicinal substances to which all practitioners of the ordinary art of healing at length reduce their practical pharmacopoeia. We will describe the manipulation of each of these applications previous to entering upon their *modus operandi* in diseased conditions of the body.

Packing or envelopment in wet sheets or cloths.—

A linen or cotton sheet is wrung out of cold water more or less strongly, according to the estimated power of the body to react upon and warm it. One or two blankets are spread upon a mattress or feather bed; the wet sheet is spread upon these; the patient is then placed upon the sheet in a recumbent posture; the sheet is then folded over the whole body, sometimes including, at other times excluding, the feet; the blankets are then folded as tightly as may be over the sheet, and as many more blankets or other woollen articles are placed upon the patient as may be deemed necessary to insure the warming of the enveloped person. In summer and in full-blooded persons this warming takes place more speedily than in winter, or in persons whose blood and blood-making powers have been diminished by previous long disease. The amount of water left in the sheet after wringing, and the time during which the patient is left in the packing, will thus be regulated by the previous history and present amount of vital energy of the patient; as also, in acute complaints, by the degree of fever which has to be overcome. Ordinarily, in chronic disorders the packing in a sheet should endure from forty minutes in summer to sixty minutes in winter; but when a raging feverishness is present, whether it accompanies a local inflammation or not, the packing should not endure more than ten minutes after the patient is well warmed in it; and this is often effected in ten minutes, especially in the case of children; so that in these instances the patient will not be longer than twenty minutes in each pack. If he were to remain for a long time after becoming warm, the heat would so accumulate as to prove an irritation to him instead of a most soothing agent when only applied for a brief period. As a consequence of this, it is very often necessary,

in strong febrile conditions, to withdraw the patient from the sheet at the end of fifteen or twenty minutes, and place him in a second cold one; and so on for perhaps three, four, or five changes, until the heat of the surface is so reduced as to allow a sense of quietude and relief to steal over the tumult and the torment of the fevered frame. This quietude is, especially in chronic diseased conditions, so great as to engender sleep of the most refreshing kind; and even in intense febrile states, sleep very often ensues upon the single or repeated application of the wet sheet, if it is not obtained during such application. On the withdrawal of the sheet the skin is found to be cooler than before the packing, and frequently to be somewhat glutinous to the touch; still it is warmer than the surrounding atmosphere; and it is to fortify it against this last, as well as to wash off all impurities brought to the skin during the warm packing, that some sort of ablation after it is necessary. In persons of scant blood and vitality the ablation which conveys the smallest quantity of cold water, or which consists of actually hot water, is the best; rubbing with wet sheets constituting the former, whilst the latter may be represented by a shallow bath at 80° to 90°. Such a shallow bath is likewise applicable in bad cases of lung inflammation, in some womb disorders, and when it is impossible for the patient to walk so as to recover perfect warmth by exercise.

The repetition of the packing in wet sheets or towels reduces the rapidity of the pulse and the heat of the skin in acute febrile conditions; it does the same in chronic conditions of disease. The propriety and the duration of its application should thus be regulated by the amount of acute or chronic irritation which may be present, of which the medical attendant should be able to make a somewhat accurate measurement. For if this process be employed beyond the necessity of the case, a considerable amount of depression of the nervous and muscular power follows. In such instances, cold sweats, fluttering pulse, and tremulous hands announce the injurious prolongation of the process in acute disorders; whilst in chronic diseases the same excessive application is signaled by considerable muscular weakness, shortened breathing, and small, weak, rapid pulse, with diminished power of warming in the packing, as well as after other hydrotherapeutic applications. When such is the case, either the process should be abandoned altogether for a time, or if in acute disease some local inflammation still demands its employment, it should be practised in a restricted manner, by means of local packings with towels, or with ordinary compresses frequently refreshed out of cold water. It should be remarked on this point, that packing of the chest over the ribs is much more reducing, both as regards the pulse and the muscular and nervous systems, than when applied to the abdomen or other parts of the body; so that when the sheet packing proves too depressing, that tendency may be qualified by packing only the body below the chest. Then again, the packing may be reduced by intermittence; using it only on every other or every third day in chronic diseases, instead of daily.

Packing generally augments the secretions of the skin and the kidneys, but not that of the bowels; which last it not unfrequently diminishes. In fact,

the increase of the former implies the diminution of the latter; for the excrementitious portions of the blood being carried off by the skin and the kidneys, there remains less to be eliminated by the bowels. That this is the case is frequently shown by the increased faecal secretion immediately on the cessation of the packing. By means of packing, the skin is not unfrequently made so active an excrementitious agent that an actual faecal odour has occasionally been imparted to the exhalations from the skin in cases where much packing was practised but small faecal discharges effected. By its means also, all kinds of exudations have been produced, conveying from the mass of blood in the body the drugs, mineral and vegetable, which had been circulating for years, and troubled both the sensations and the nutrition of the frame.

From all that has preceded, it will be plain that the wet sheet packing or envelopment is only applicable when the morbid phenomena are those which come under the epithet 'excitement.' Further, it is necessary that the excitement should be more or less of the febrile character: that there should be one organ, or one set of organs, in feverish action, whether that action involves other organs so as to produce general feverishness or not. In acute disease this last condition, that of general fever, is the usual signal for the packing in the wet sheet; but in chronic disease, individual organs are constantly found to be feverishly acting without involving the rest of the body in the same kind of action. Thus we constantly find dry tongue and other signs of fevered stomach, whilst neither the skin nor the pulse respond feverishly. In such cases the partial packing with cold wet towels is successfully applicable. For this reason it frequently becomes necessary to pack only the hips and loins, the belly only, the lower back only, or the chest alone; and this the rather if the body is in a comparatively bloodless state, although affected with irritated womb and kidneys, irritated stomach and bowels, with inflamed piles, or with bronchial irritation, respectively. In this, as in the former case of general fever, it may be necessary to change the packing repeatedly, according to the rapidity of warming in it: that being the measure of the local fever to be subdued. After this local packing, it is necessary to bathe or rub the parts which have been packed with water or towels at varied temperatures, according to the quantity of blood and vitality of the patient; but if these last be in proper quantity, a general ablation or friction follows the local packing. Thus, after packing the hips and loins, a shallow bath or friction all over the body with a dripping sheet may be practised; whereas if those attributes of blood and vitality be deficient, the ablation or wet friction should be restricted to the hips and loins; and the local irritation is in this way subdued without trenching upon the restricted vitality of the general frame. In this manner these local packings come to play an important part in the hydrotherapeutic management of disease, and especially of chronic disease. Frequently, by subduing the local feverish action which was perturbing the whole nervous, digesting, and circulating organs, causing waste of the frame without fever, the local packing has released these last named organs from the interference, and enabled

them to resume healthy sensation, digestion, and circulation. They should, therefore, be by no means passed over in a record of the measures of the hydrotherapeutic method; especially in chronic diseases, in which it is very frequently necessary to commence the treatment by such partial applications, and only subsequently have recourse to stronger and more extended applications.

Cold and Hot Fomentations.—Cold fomentations are effected by applying a towel, more or less strongly wrung out of cold water, over any organ in which there is reason to believe that irritation of a febrile character exists, which excites tumult in other organs. Thus the digestive organs may be keeping in wakeful excitement and sleeplessness the whole of the brain and spinal cord; and cold fomentations applied over the former will bring quietude and sleep to the latter. In this process, as in that of partial packing, the wet towel is covered with a dry woollen tissue; but it differs from the partial packing in the more frequent change of the wet towel. It supposes, in fact, a more intense amount of irritation to be subdued—an irritation verging on the acute, and in which it is necessary to draw off as much heat and feverishness as possible, and in as short a time as possible. In this process, therefore, the towels are changed every fifteen or twenty minutes; and this is continued for one, two, or three hours, until, in short, the towels cease to become warm in the time specified. Nor when they become warm should they be allowed to remain on the skin; another cold towel should immediately be applied. The soothing result is, in this case, left to the subsequent reaction to the surface, and not to the soft warmth, as in partial packing; it is not until some time after the wet towel has been withdrawn, that the soothing action on the nervous system is distinctly experienced. As before mentioned, intense irritation of the belly may be met by this process, especially in general fever, both of the nervous and inflammatory kind; so also may febrile irritation of the uterine organs, either with or without excessive secretion; irritable spinal cord; irritable brain; and even irritable heart, if this is connected with stomach derangement, but not if it has a mental or hysterical source. Over the large joints—the knee, the shoulder, and the elbow—the cold fomentation is useful, when their irritation is *within* the capsule of the joints, and of a sufficiently acute kind. In all these cases the fomentation should be continued until the skin underneath is perfectly cold, and no more heat comes to the surface; the process is then to be discontinued, and dry woollen cloth placed over the skin, which then begins to react strongly towards heat, bringing with it the interior irritation, whether of a visceral cavity or joint. In cases in which the cold sitz is not possible, or is at least inconveniently applicable, the cold fomentation may be profitably employed. In, for instance, uterine hæmorrhage, when the sitting position would be harmful or impossible, cold wet towels applied to the lowest belly and the lowest back, and frequently changed, have the tonic effect of a cold sitz bath of short duration. In hæmorrhage of the lungs, this process is useful over the chest in front, and between the shoulder-blades; and in severe but painless diarrhoea, over the lowest back and belly. As a general rule, cold fomentations

should be applied in the morning or at noon, when the nervous power is least likely to be at a low ebb.

Hot fomentations are effected by placing a four-folded flannel at the bottom of a basin, pouring thereon as much hot water as will saturate it, wringing the flannel well out, applying it over the affected part, covering it with a thick dry flannel or blanket, and changing it for a freshly-wrung flannel every three, four, or five minutes, according to the intensity of the irritation to be thereby subdued. The duration of the application also varies with the same circumstances, and may range from twenty minutes to two or three hours.

Hot fomentations are most useful when the contents of the belly or of joints are in a state of acute and painful irritation. A high degree of heat, say 120° to 130° , applied in this way, is most beneficial in inflammatory mucous disorders of the abdominal viscera; but if the inflammatory action be low, and the nervous irritation predominant, a heat not higher than 110° is more appropriate; in fact, a high degree of heat would, in such case, augment the interior tumult. A joint, for instance, which in a purely neuralgic or neuropathic state, however great may be the pain, would derive no benefit, and might be exasperated by very hot fomentations; and the same applies to hysterical colic, neuralgic womb, and nephralgia or neuralgia of the kidney. So also in fevers of the nervous character they are inapplicable, and cold fomentations are preferable. Dry or loaded tongue, heated throat, thirst and inappetence; tender, distended belly; throbbing, oppressed, or excited brain; and general restlessness—are signs which indicate fomentations at 120° for half to one hour at a time over the belly: and this may be repeated after intervals of two to six hours, as the symptoms are maintained or mitigated. In the prolonged incubating stage of the worst kind of fever, when the abdomen is burning and the extremities freezing; the pulse small, weak, rapid; the brain clear when roused, but ready to sink into apathy (a state in which alcohol is freely administered in the ordinary style of medication)—fomentations at 120° over the belly may be continued for three or four hours, with the effect of driving blood and warmth to the limbs, and deriving it from the head, and so establishing the fever all over the body, but saving the belly contents and the brain from its special ravages; but the general fever once established, it is not so much indicated—not at all, in fact, if the fever be of the purely nervous type. In acute indigestion, hot fomentation is of the greatest benefit; and in that case it may be applied immediately after cold fomentation; and it may, likewise, be used in severe general catarrh occurring in the spring, and caused by east wind. Applied to joints, it may be for the purpose of soothing acute inflammation within them, or of rousing the nervous action when the inflammation, no longer acute, has sunk into the most obstinate chronic apathy; and in the former of these instances it should be at 110° , in the latter at 130° : but in both cases it should be of long duration. It is not applicable to gouty inflammation of the small joints, compresses from cold water frequently changed being more appropriate; but it is applicable to acute rheumatism of these joints, which is the result of cold. It is useful immediately after a severe bruise or contusion, but after

eighteen or twenty-four hours it is less so; and if the contusion be in hard, fibrous tissues, such as the sinews and ligaments, the heat should be great; in soft tissues lower. In the severe pain of the lower back, caused by internal piles, fomentation of that region at 120° , and continued for an hour or more, is useful; as also in inflamed and protruding piles, but the temperature should then not exceed 105° , and should be frequently repeated. Fomentation of the upper spinal column for twenty minutes at bedtime, at a temperature not higher than 110° , frequently induces sleep. As a general rule it is best to use hot fomentations at bedtime, when no further mental or locomotive exertion is called for. The indications of its excessive or inappropriate employment are, general sense of faintness and prostration soon after it, excessive moisture of the skin, profuse flow of urine, palpitations of the heart, and throbbing in the head. These two last signs are mostly experienced during the process of fomentation, and should cause the immediate stoppage of it; nor should it be repeated for a day or more. Any or all of these untoward signs are sure to be exhibited if hot fomentations are applied over the ribs; it is never proper to apply it on the respiratory system of nerves.

Compresses are pieces of folded towelling, mostly four-folded, wrung more or less completely out of cold water, and covered with dry thick towelling, flannel, or some waterproofed tissue. As the compress rather proves an irritant than a sedative when it becomes dry, which it does more readily when covered with flannel than with mackintosh, the latter article is preferable, unless the patient takes care to refresh the cloth out of cold water, and not allow it to remain dry; but with whatsoever cloth it be covered, it is best to refresh it frequently if it becomes very hot, whether the heat be dry or moist. It is for want of this precaution that stomach compresses, for instance, so often produce gnawing at the pit of the stomach, faintness, hysterical pathos, and even nausea. It may be said generally, that if the wet compress becomes speedily and very hot, it cannot be refreshed too often, in order to insure its counteracting and sedative effect. In fact, it is packing on a small scale as regards the extent of surface enveloped, and should follow the same rule; which is, that the more speedy and thorough the warming, the more frequently should it be cooled again—the object in both cases being to exhaust the irritation underneath as completely as possible. Compresses are applied to all parts of the body, either to subdue irritation on the surface, or to bring it to the surface from within. For the latter purpose it is used in both chronic and acute irritations and inflammations of all the great cavities and interior organs of the body; of the belly, in almost all shades of gastric disorder; in constipation; in renal disorder, especially of the lithic kind; in congestions of the ovaries and womb; of the chest, in all shades of lung inflammation; in pleurisy; in rheumatic disease of the heart and its envelopes; in hæmorrhage from the lungs. For the purpose of subduing irritation on the surface, it is used in acute gout and rheumatism in any joint of the body; in the chronic form of those complaints; in all kinds of skin disease; in local neuralgia of the skin. It will thus be seen how almost universal is the applicability of this simple remedy; and it seems

to have been the first to break through the wall of prejudice opposed to hydrotherapeia by the practitioners of ordinary medication; for, without abandoning drugs, numbers of them are employing the cold wet compress, especially over the belly, although its soothing effects are even more strikingly exhibited in maladies of the chest. And here it may be mentioned that compresses applied to the chest are much more subduing in their effects on the nervous system generally, than when applied over the belly; as is the case in packing, which includes the chest. But although so widely useful, compresses require to be managed in strict accordance with the reactionary power and personal peculiarities of the patient. Thus it may be necessary to wring the towelling very slightly in one patient, and very strongly in another; to keep it on only two or three hours instead of all day; to wear it only for two or three hours after a meal, never on the empty stomach; to wet it afresh more or less frequently; to cover it more or less warmly, &c.—conditions which the acuteness of the practitioner, aided by the report of the patient's sensations, must discover and act upon, but which no written statement can more than very inadequately point out. Not unfrequently the skin breaks into a diffused or papular eruption of a burning or itchy character, after the compress has been worn for some time. This is plainly due to the repeated reaction of the skin upon the cold surface of the compress, and is very often useful when it takes place over the interior irritations of the great cavities; but it is of more doubtful benefit when it takes place over joints, when the irritation to be subdued is in the closest proximity to the cutaneous inflammation thus produced; for in such case this inflammation reacts as an irritant upon the original seat of disease, and aggravates it. For this reason, when the skin inflames in consequence of the compress, over a knee joint, for instance, it is better to omit its application for a time, and renew the inflammation of the skin afterwards, than to persevere in maintaining and increasing the latter; whereas, when the compress causes an eruption on the chest or belly, it should be kept up as long as possible, since its action is continuously to subdue interior irritation without the risk of augmenting it. In some persons there is an incapacity for wearing the compress over the stomach by day, because it causes trembling of the limbs and general failure of nervous power. When such is the case, it should be worn at night when the limbs are not called on for exertion. If it become so hot in sleep as to wake the wearer, it should either be thrown off altogether or refreshed. For the rest, a compress over the upper stomach is one of the surest ways of obtaining sleep when the nerves are excited from any cause.

Cold Sitz Bath of long Duration.—This bath acts as a sedative, by withdrawing blood from the brain towards the lower parts of the trunk. This withdrawal of blood is shown in the paler countenance of the patient, and may go to such an extent as to cause faintness. Very frequently it so far subdues the excitement of the brain by withdrawing blood from it, as to induce sleep whilst the patient is sitting in the bath. But whilst it thus causes the withdrawal of blood from the upper organs of the body, by that very process it attracts blood to the

lower organs which are immersed in the water, and induces increased activity in their sensational and secretorial functions. In this manner the long cold sitz bath unloads the brain and liver of blood, and causes improved opening of the bowels, relieving in a double way the congestions and oppressed functions of the upper organs. In like manner it improves the deficient monthly secretions of women, and the quantity and quality of the urine. The duration of this bath varies from fifteen to forty-five minutes, according to the effect which it is desired to produce, and the temperature of the weather and water. When the head or liver is very much congested, especially in apoplectic fulness, the bath can scarcely be too long, and its temperature should be kept down by the frequent addition of cold water, so as to withdraw heat and attract blood as much as possible; but when the congestion of the brain tends towards the atonic kind, without there being real atony of that organ, the duration should be restricted to fifteen minutes, and only augmented after close observation of the symptoms. In cold weather the same effect can be produced by a sitz of fifteen minutes that can be obtained by one of twenty-five or thirty minutes in warmer weather. On this account it is that some hydrotherapeutic practitioners employ in the summer time a sitz bath in which the water is always flowing through whilst the patient is seated in it; the temperature is thus continuously kept at the lowest degree of the season. Reaction after this bath is essential; therefore in chronic complaints brisk exercise should always be taken after it; in fact, the bath is not applicable when the locomotive powers of the patient are small. But the long cold sitz has frequently a wonderful effect in acute febrile complaints, in which there is heat and blood enough to produce attraction and reaction without subsequent exercise. In typhoid fever, when the head is becoming oppressed to the extent of producing stupor, nothing conduces so powerfully to its awakening as a very cold sitz of half or three-quarters of an hour's duration, especially if it is maintained at its low temperature by the addition of ice; natural sleep, with perspiration, frequently follows such application. It is also beneficial in ordinary sthenic fever, when the brain is sleepless, and general restlessness prevails. In acute pneumonia, after sufficient sheet packing, a long cold sitz often reduces cough, and promotes expectoration; a result frequently obtained, notwithstanding its antagonism to long-standing prejudices. In this bath the pulse always falls considerably in rapidity, so that in prescribing it reference must be had to the power of the heart, and the quantity and quality of the blood in the patient; it is not adapted for those with poor and scanty vital fluid.

Tepid Sitz Bath.—The temperature of this bath moves between 80° and 90°; more or less heat than this is apt to stimulate and cause reaction, whereas this bath is employed where reaction would be undesirable or impossible. It is intended, in short, to calm the nerves of the lower regions of the trunk in cases where, from deficient blood, or deficient nervous power to circulate it, the long cold sitz bath is impracticable. If the state of the brain be purely atonic and restless, this bath is good for quieting it; if a patient be far gone in atrophy, and yet cannot procure sleep by night or quietude by day, this bath is

the best for him. Also, when the walking power which is necessary for the purpose of reaction is deficient, the tepid sitz bath accomplishes the derivation of blood from the upper organs of the body, and so calms their irritation without the exercise of that power. It should always be remembered, however, that whenever, from the circumstances of the constitution, the derivative effect of a long cold sitz is possible, its effect is more decided and permanent than the tepid sitz.

General Warm Bath.—The temperature of this bath may range from 80° to 95°. Above these degrees of warmth it becomes a hot and stimulating bath, provocative of quickened circulation of blood, especially in the brain, and of excitement of the nervous system. When it is desired to apply only such an amount of warmth to the external surface of the body as shall not demand reaction from the interior organs, the temperature of the bath should not exceed that of the skin by more than five to ten degrees, and should not exceed that of the blood, which is about ninety-six degrees. According to this rule, a tepid general bath will be applicable in the same kind of cases as the tepid sitz above-mentioned; with this difference, that whereas the tepid sitz soothes by withdrawing blood from the upper to the lower organs of the body, the general tepid bath acts by taking the entire surface of that highly-sensitive organ, the skin, out of the irritating action of the atmosphere, by applying to it a temperature which is grateful without being stimulating; and thus, in the quietude of the cutaneous nerves so produced, the brain will often go to sleep, or at least cease to be irritable. This bath is used after packing in the sheet or towels, and after sweating with the lamp, in all cases where it is either impossible or undesirable to produce much reaction: as in catarrh, which does not allow of muscular exertion; in measles, scarlet fever, and other acute eruptive complaints; and in all cases of deficient blood, or deficient nervous power to move it equably. There are some chronic skin diseases in which it is not well to induce strong reaction after packing or sweating, but in which these two processes are necessary; in such cases (they are chiefly moist tetter and tendency to boils) the tepid general bath should be made to follow the processes alluded to, rather than the cold or the very hot bath, which would only exasperate the outward explosion of skin eruption. The duration of this bath may be from three to ten minutes: the longer time being intended when the object is to procure general calm of the nervous system, and the shorter time when its purpose is to wash off the skin the secretions eliminated by packing or sweating, as in cases of skin disease before-mentioned.

Passing from the list of soothing and subduing hydrotherapeutic processes to those of a stimulating character and aim, these will be mentioned as nearly as possible in the order of their stimulating power.

Friction with Wet Towels and Sheets.—As in packing, so in friction, there must be sometimes local and piecemeal friction with towels, and at other times general friction with sheets. The relation of the nervous centres to the nerves of the skin must, in great degree, determine the use of the partial or general friction with wet cloths. If the skin is very sensitive and somewhat bloodless, whilst the brain and

spinal cord are exceedingly excitable, the skin should be stimulated gradually, so as not to throw too great a shock upon the nervous centres at once. It is then best to rub the trunk and arms with wet towels, the lower limbs being covered warmly meantime; then to dry the trunk and arms, and dress them; and finally to proceed to the friction of the lower extremities. Cold stimulating friction will thus frequently be tolerated, and strong reaction gradually established, when if an entire wet sheet were thrown over the body, the brain and spinal cord would indicate the excessive shock applied to them, by giddiness, faintness, or subsequent headache. After several days of this timid rubbing (after weeks in some tedious instances), it is possible to employ the whole sheet; for by that time both skin and brain have become accustomed to the kind of stimulation, which may then be beneficially extended. Further, it is necessary in not a few cases of chronic disease to commence friction with towels and sheets having had the water very strongly wrung out of them—to be only damp, in fact; and by degrees to contract the amount of wringing, until at length the linen is applied in a dripping state. Dripping towels and sheets applied with friction are used both after packing and sweating, and without those processes. They have the result of fortifying the skin against cold-catching, and they are useful after exposure to heat, provided there be not very great fatigue of the nerves; they tend to disperse external neuralgia of the scalp, and of the face and teeth; external cramps of the trunk and limbs; as well as that condition of the nervous system which accompanies hysterical and melancholic depression—in all which the wet sheet is, of course, more potent than the fractional application of towels. The friction should always be applied vigorously, rumpling the sheet in the act, and it should be continued for from two to four minutes, beyond which time it becomes too warm to be stimulating; although it is sometimes directed to refresh the cloth out of cold water, and renew the rubbing for another four or more minutes. It is of no utility to wring these cloths out of warm water: begin the use of them with ever so little moisture in them, but let it be cold moisture.

General Cold Bath.—This is an advance upon the last process in the direction of stimulation. When in the commencement of the treatment of a chronic malady it has been deemed necessary to initiate stimulation with sheet-rubbing, it is desirable to leave that, and pass on to the present bath so soon as the patient gives signals of power to react upon a stronger agent than the dripping sheet. In acute disease, when it is of a very feverish character, the cold bath may follow upon packing or sweating; the exceptions to this being cases of pleurisy, pneumonia, peritonitis, and rheumatism of the heart, where, from the extreme sensitiveness of the organs implicated, the effort of strong reaction should be avoided. By the general cold bath is to be understood a long bath containing from six to eight inches of water, in which the patient sits and submits to constant splashing and rubbing for a space varying from one to ten minutes. The patient should not be motionless for a moment; rubbing and splashing should be going on incessantly, in order to produce the greatest amount of nervous action, of blood, and of warmth to the sur-

face, which much subsequent dry friction tends to augment. It may be prudent to wet the head, or at least the back of it, before taking the bath, but it is by no means essential in the majority of cases. A few persons are so sensitive in the feet, that they cannot bear them in the bath without pain both in feet and head; in which instances the ablation of the body must be effected in a large sitz bath wherein the feet do not enter. The general cold bath is that which is prescribed for ordinary use on rising every morning, as well as after other processes, such as packing and sweating. It is very commonly ordered as the 'shallow bath,' inasmuch as it is not intended that the water should reach above the hip-bone, nor higher than to cover the thighs. The repeated shocks of splashing and of friction constitute its chief stimulating agency; the constant beating of a small quantity of cold water being more potent in causing reaction to the surface, than absence of motion would be in a deep bath reaching to the throat. Occasionally Priessnitz would cause patients to remain in this bath from half an hour to an hour, rubbing them vigorously all the time, and renewing the water as its temperature rose; and it is alleged that he more than once succeeded in rousing a patient from the stupor of congestive or serous apoplexy by these means, and probably in consequence of the enormous quantity of blood brought to the surface.

Cold Pail Douches.—In this process the patient sits down in a long bath with no water in it; two, three, or four large pails of water are then poured, or rather thrown, at the upper part of the back and on the chest, in the proportion generally of two-thirds on the back and one-third on the chest. The force with which they are thrown must depend upon the nervous and circulating power of the patient, the former especially; for it might produce giddiness or headache by the shock. When the pails have been thrown on the body, the same splashing and rubbing as in the general cold bath ensues; in fact, the pail douche is the shallow bath *plus* the shock of the water thrown on the surface at the commencement. There are persons in whom this additional stimulation is necessary, to insure strong redness and reaction of the surface; these are mostly of pale complexion, soft flesh, and apathetic mentally, who require the lamp and sweat rather than packing—who tend to congestion rather than irritation. The pail douche is administered after packing and sweating; but is, upon the whole, more applicable after the former than the latter, inasmuch as the brain is more quiet, and not so liable to be disturbed by the shock. It would be a very dangerous bath to give where the body is fatigued with exercise, or the brain filled with blood in consequence of mental labours. Sometimes it is desirable to break the shock of the cold pail douches by making the first one which is thrown of a high temperature, from 90° to 100°; this gives an artificial warmth to the skin which breaks the shock of the subsequent cold pails, and, moreover, tempers the water in which the ensuing friction is to be practised. Sometimes, also, the first pail is given at 90° or 100°, and the second and third at 60° or 70°. All this is matter for regulation by the medical attendant, who should be able to measure the patient's capabilities beforehand. Cases of atrophy, of nervous decay from excessive mental

exertion or excessive sensual indulgences, are those which mostly require this graduation of the stimulating shock of the pail douche; but this should always be done with the object of eventually reducing the temperature to the most stimulating degree.

General Bath of High Temperature.—This bath constitutes another mode of stimulating the exterior for the purpose of relieving the interior of the body; and it is especially applicable where the nervous currents of the frame are slow and low, even though there may be a sufficient supply of blood in it. In other words, if there be atonic congestion of the brain and spine to such an extent as to prevent the flow of nervous power thence to the interior organs and to the external surface, the application of great heat all over the latter is a method of releasing the oppressed brain and spine, and of allowing them to send nervous power where it is deficient. It has the same aim, in short, as the lamp sweat, but it is effected with less taxation of the nervous power, and followed by less languor and, perhaps, headache; neither does it consist of two processes, as the lamp sweat followed by the shallow bath does. As may be supposed from what has been repeated in this article, the general hot bath is only palliative or introductory to colder treatment, in chronic disease. For that end it is desirable, very shortly after commencing its use, to have the body rubbed with cold wet towels or sheets on coming out of it, and before the dry friction; and whilst this is being done, the temperature of the bath itself should be gradually and steadily reduced at each time of its application. This may be done sometimes by adding cold water to the bath whilst the patient is in it, as well as by the cold friction just mentioned; but the diminution of temperature each day is upon the whole preferable and more certainly ascertained. In acute disease, the general hot bath is applicable in asthenic catarrhs, such as influenza, in the shivering stage of feverish catarrhs, when it is desirable to curtail it and induce the hot or perhaps the sweating stage, and in sleeplessness unaccompanied with the signs of inflammatory action. It is useful also in spasmodic and neuralgic pains of the kidneys, bowels, bladder, or womb; but it is of no use in actual inflammation of these organs, nor in the same pathological state of the lungs, heart, or brain; in short, it is a stimulating, and not a soothing and subduing process—it stimulates by heat instead of by cold. In furfuraceous and crustaceous skin disease it is often useful, after packing in a wet sheet; but it is not applicable in moist herpetic nor in papular eruptions, in which it stops itching for the moment only to augment the depth to which the inflammation of the skin dips, and thus eventually increase the itching. Upon the whole, being one of the least characteristic processes of hydrotherapeia, it has the smallest range of application.

Shower Bath.—This may be called a general bath, but its chief place of application is, in fact, the head and back. In old practice, warm and tepid shower baths were employed, but in hydrotherapeutic practice these are represented by tepid or mingled pail douches, as more readily obtainable. The shower bath, in the last-named practice, is not employed until it can be applied as a cold stimulant to the nervous system, through the shock which it affords

the nerves of the skin. In this manner it becomes a very powerful agent in dispersing congestion of blood in the nervous centres, both sensific and nutritive; but it must be shown that such congestion is unaccompanied by even the smallest amount of inflammatory action in brain or spine, or in any of the interior organs supplied with nerves from that source. In the cerebral and spinal congestions which induce depression of spirits, depression of muscular activity (paralysis in various degrees), hysterical movements, twitching and convulsive movements, neuralgia, especially of the intermittent and erratic kind, the cold shower bath is eminently serviceable, either as an introduction to the stronger measure of stimulation afforded by the falling douche, or in alternation with it. Of a certain kind of stimulation—that which is evidenced by shiverings—the shower bath is a stronger provoker than the douche just alluded to; the dropping of thousands of small cold points is more irritating to the skin-nerves than the impinging of a heavy mass of water; but the latter, both from its weight and the quantity of cold conveyed in it, stirs more profoundly the nervous centres themselves. This is the reason why in the list of general stimulating processes the shower bath precedes the douche, towards the employment of which it tends. The question of the application of the shower bath to the head hinges upon the tonic or atonic fulness of the brain. If there be abundant blood in the whole body, and the head suffers, it suffers because there is relative excess of blood in the brain, and it is passing forcibly through it; in such case the cold shower may fall on the head for a brief time—not during the whole continuance of the bath. But if the body be wanting in blood, the vessels of the brain are most certainly filled in the atonic way; and in that case it will not be right to stimulate strongly the head by the shower, because it would be followed by reaction toward the brain, whose vessels are too weak to rid themselves of the blood thus driven towards them; in atony of the brain-vessels, therefore, the shower should not be allowed to fall upon the head. But in baths properly fitted up for hydrotherapeutic treatment there are to be found *lateral shower baths*, the play of which is directed towards the back and front of the trunk at the same time, or against one part only at a time, and this kind of bath is frequently bearable when the falling shower bath would excite the nervous centres excessively. These lateral shower baths are of much benefit in abdominal congestion, in flatulent indigestion, in bad secretory action of the kidneys, in uterine congestion and neuralgia, in chronic lumbago, and all ailments marked by sluggish circulation in the abdominal and pelvic organs. The duration of the falling shower bath should not exceed two minutes; whereas the lateral shower bath may be taken as long as five minutes, and is occasionally followed by the heavy-falling douche on the hips and legs, for a minute or two.

Falling Douche.—The stream of water which constitutes this bath varies from one to three inches in diameter; and the height from which it falls varies from twelve to eighteen feet from the back of the recipient. It will be readily conceived that the body of water so falling acts as a very powerful stimulant to the nervous centres, and requires pre-

paration and care in its administration. In fact, it is the most potent of all the stimulating processes, and, as it were, the crowning of the excitant treatment, when such is demanded. Beginning with frictions with towels and sheets, the nervous system, however weak and excitable, may be made at length to tolerate the heaviest douche, by gradually passing the body through the graduated stimulation of tepid general bath, then of cold general bath, of mingled pail douche, then of totally cold pail douche, of spinal washing, and of shower bath, by which time the nerves of the skin and their origins in the spinal cord are well able to bear the weight and cold of water falling from a height of eighteen feet, at the rate of seventy gallons in a minute. This has been abundantly proved during the last thirty years, although it is denied by those practitioners of the old school who have never seen hydrotherapeutic treatment. This tolerance of so much stimulation has, for the most part, to be arrived at by the graduation just mentioned; but it is equally certain that in not a few cases the patient, having abundant blood, but having it accidentally congested in one or more points, is able from the commencement to react upon, without failing under, the stimulation administered by the falling douche. The process by which this bath operates is plain enough, and has just been alluded to. The violence and the cold of the water shock the thickly supplied nerves of the skin, and rouse them; the shock is propagated along those nerves to their origins in the spinal cord, and thus this latter organ eventually receives the stimulation of the application. Receiving it, the spinal cord propagates it toward the brain, on the one hand, and along the nerves which it (the cord) sends to the interior organs—the heart, lungs, stomach, &c.; and in this manner is explained its effect in producing appetite and digestion, in reducing flatulency, in promoting the secretions of the kidneys, bowels, and womb; but in this manner also is explained its occasional action, when imprudently administered, of causing giddiness, throbbing and sleeplessness of brain, spitting of blood, palpitation of heart, nausea and vomiting, and excessive flow of urine. But besides these reflected actions on the interior viscera, the spinal cord sends the effects of its stimulation along the nerves which it sends for locomotive purposes to the limbs and voluntary muscles generally, and thus energy is given to those muscles; but should the stimulation of the cord have gone beyond the point of tone and reached that of tumult, we have, instead of alacrity of locomotion, disinclination to it, with a sense of fatigue and languor. This rationale of the operation of falling douche points at once to its potency as a therapeutic agent, and to the care necessary in employing it. With this in view, it is well for the first few days to limit its application to the extremities of the nerves of the spinal cord, in other words, to the upper and lower limbs and the buttocks, and only by degrees apply it to the back and spinal cord, where it would impinge on the roots of those nerves, and of course be more liable to produce excessive tumults therein. When it is judged to be prudent to apply the douche upon the spinal column, it should be passed rapidly across the back by an appropriate movement of the trunk, and not be allowed to pause upon any point of it.

The most usual proportion of its application is one-third of the time to the back and two-thirds to the limbs, or one minute to two minutes; but in many cases of paralysis and neuralgia the time may be extended to six or eight minutes. Rarely is it administered twice in the day; and mostly, when it is so, in old standing rheumatism, neuralgia, and palsy. In persons of sensitive temperament, a sufficiently stimulating result is often obtained by receiving the douche on the limbs alone. But in all cases it is desirable that its operation should be watched; the patient should never be permitted to continue the employment of it without frequent inspection. It is well known that disastrous results at Gräfenberg followed on Priessnitz prescribing the douche and never seeing the patient for two or three weeks. The signals of the irritating, as distinguished from the tonic effects of the douche, have already been mentioned, and more or fewer of these suffice to indicate the necessity for intermission, suspension, or diminished time and space of application. If, for instance, the bath is causing fatigue instead of exhilaration, it should be taken from the spine, administered only on the limbs, and perhaps curtailed in time of application. If broken sleep attends its use, it should be taken two or three times a week, instead of every day. But if to this is added palpitation of the heart and irascible or lachrymose irritation of mind, the process should be suspended altogether, for a time at least, until these symptoms subside, and if the bath be considered necessary for other existent morbid symptoms. In order to avoid these irritating results, the bath should never be taken at too near a distance from the head; from a line drawn across the middle of the shoulder-blades downwards is the most eligible space for it to fall upon. Comparatively few persons can bear its application on the nape of the neck. Occasionally, in cases of torpid liver, the douche may be allowed to fall over the region of that organ; otherwise, it is not prudent to allow it to play upon the belly. It remains to state that the douche is beneficially applicable for local complaints; for torpid swellings of joints or glands, for local palsy of hands or legs (as in painter's palsy), for sprains, after the inflammatory stage is past, for very torpid lepra, &c. Applied to the feet, especially to the soles of them, it is an efficient mode of warming them. The douche should never be taken when fatigued by walking or other exertion; the exertion should follow, not precede it, and even then not for so long a time as after the sitz bath.

Plunge Bath.—This is taken alone, or after packing, lamp sweat, or vapour sweat. It is only an increase of the general cold bath and the pail douche, and is prescribed when the object of treatment is in all ways to induce a tumult in the system, with the view of rousing a critical, or, at least, an altered action in the body generally, or in some of its principal organs. Such tumult is more especially desirable in long standing rheumatism, characterized more by stiffness than by pain; in obstinate congestion and torpor of the liver and of the abdominal organs generally; and in paralytic conditions which are unattended by cerebral or spinal-irritation. In some inveterate forms of skin disease, also, of the crustaceous or furfuraceous kind, the additional stimu-

lation of a plunge bath after the sweating process will often be found useful. On the other hand, it should not be employed where there is active or even atonic fullness of the brain; where there is pulmonary obstruction from any cause; where there is weak or abnormal action of the heart; where there is general bloodlessness; or where there is suspicion of fatty accumulation about any of the internal organs. The duration of this bath should in no case exceed five minutes, and constant movement and friction should be used during it.

Partial Sponging with Cold Water.—This is the first to be mentioned of the partial applications of water to the body. As in the instance of the towel rubbings, this is a process to be practised when, from the defective nervous and circulating powers of the frame, a general bath would not be applicable. When with this general defect a dry, harsh, lifeless skin presents itself, a piecemeal sponging is all that can be applied in the onset of treatment, or subsequently to friction with wet towels. The patient sits down, having the lower extremities alone covered with blankets; the trunk and arms are rubbed well with wet towels for two or three minutes, and then are sponged freely with cold water for a minute or two, dry friction following upon that. The previous preparation of the skin by broad and wet friction renders it more susceptible to, and therefore more ready to react upon, the punctuate stimulation of a cold splash, and activity of the skin is thus better insured. After free sponging and abundant friction of the trunk and arms, the same double process is gone through with the legs; the trunk having been warmly enveloped meantime. The repetition of this leads gradually, as before explained, to the more general baths of stimulation and tone. If, without being dry and harsh, the skin is only bloodless, but tolerably warm, the sponging may be used at once, without any previous friction with towels. Sometimes also dry friction with a hair-glove, or with a rough towel, for two or three minutes renders the subsequent sponging more agreeable and more certain of reaction.

In congestive irritation of the brain, in which heat of head and sleeplessness are prominent symptoms, sponging of the hands and arms up to the elbows with cold water often proves beneficial, by inducing sleep when the limbs have become warm. Such sponging should continue for three or four minutes. The same is useful in nervous headache, in face-ache, and in toothache of a purely neuralgic kind.

Another partial sponging is that applied to the nape of the neck and back of the head. It is useful in those numerous cases of neuropathia which take their principal source in the congestion of the cerebellum, the medulla oblongata, and the base of the brain. The repeated and prolonged stimulation—for it should continue for two or three minutes—tends to disgorge the congested bloodvessels of the parts within, whilst by the process of reaction a quantity of blood is brought outwardly to the tissues of the neck. The sponging should be practised two or three times a day, holding the head over a large bath or basin. Administered near to bedtime it is somewhat uncertain in its action on sleep—sometimes inducing, at other times preventing it. As a general rule, it causes sleep when the patient has a fair

quantity of blood in the body, and it precludes sleep when the blood is very deficient in the body, although excessively congested in the posterior regions of the brain; in other words, it is calming when there is more or less of apoplectic fulness, and exciting when there is a purely atonic state of the cerebellum. Partial sponging has been carried to a most ridiculous extent by certain pretended practitioners of the water treatment, who amuse the weak-minded by sponging the nose, one hand and not the other, &c., whereby the minds in question are amused, and their bodies, though not cured, not injured.

Short Cold Sitz Baths of still and of running water.—The stimulation of this kind of bath is more particularly required in conditions of the pelvic viscera which indicate relaxation of the bloodvessels from defective innervation, with excessive secretions from them. Thus it is applicable in painless or even in painful diarrhoea, if the discharges are large and liquid, and the more if the malady is of long standing. For the same reason it is applicable when the womb gives evidence of its atonic and relaxed condition, by falling down in the pelvis, by emitting leucorrhœal discharges in the intervals between the monthly illnesses, and by profuse or prolonged discharges at the period of those illnesses. When there is general puffiness, relaxation, and heat of the feminine organs of generation, this kind of bath is most appropriate. In disorders of the male organs of generation, such as seminal weakness and impotency, spermatorrhœa and nocturnal pollutions, the bath is appropriate for the same reason. And in the minor degree of relaxation, shown in heat, weariness, and aching of the hips and loins after excessive muscular exertion, the short cold sitz bath will be found to be very useful. After sedentary and intellectual labour, it has a wonderful effect in clearing the brain, renewing the nervous alacrity, and producing appetite for food and easy digestion thereof; in this way it is a most desirable termination of a hard-worked professional or commercial man's day, and antecedent of his dinner; he can do no more profitable thing for his health, than to take a cold sitz bath of five to ten minutes, with a cold wet towel on the head during it, as soon as he returns home for the evening. A person sleepless, restless, and hot at night, will be calmed and cooled if he rises and takes one of these baths. In sudden and transitory headache, arising possibly from a surprise or from nervous shock from any cause, the short cold sitz with cold to the head should be tried; and it is well to follow it immediately with a foot bath of cold water and mustard. Very frequently, in cases where this bath is applicable, the body is in a state of nervous or feverish excitement, which precludes the necessity for walking after it; in fact, in the case of excessive pelvic discharges, walking is not desirable.

As the whole virtue of the short cold sitz depends upon the low temperature of the water, it becomes necessary to devise a method of retaining the coldest degree throughout the process. In the very cold time of winter this may be found in the ordinary spring water, which is usually at 35° to 50°; but in summer this point is gained by constantly changing the water by sending it running through the bath, so as to prevent a rise of temperature by the withdrawal and accumulation of animal

heat from the patient's body. Hence the running sitz bath becomes a necessary apparatus of all water-cure practitioners. In domestic treatment this may be substituted by the addition of ice, or failing that, of nitre and bay salt, to the water.

Spinal Washing.—This form of local stimulation was first introduced by Dr. Gully. When there is reason to believe that the spinal marrow is much congested with blood, and, in consequence of that, is sending irritation along its nerves to the skin and other organs, or when the congestion therein is so great as to diminish the power which should flow to those organs, it is desirable to stimulate the bloodvessels of the spinal marrow itself, because the extremities of its nerves on the skin are either too irritable or too torpid for healthy reaction. On these conditions is based the necessity for some such process as the spinal wash. Add to this, that when the spinal marrow is in either of the states just indicated, there is always some deficiency in the quantity of blood in the body, or some defect in its quality, which renders *strong* cold stimulation of the entire skin inappropriate. This double state of congested spine, and very defective vitality of skin, therefore, is that which requires the spinal wash. Spinal exhaustion and congestion from any cause thus becomes the indicative sign for its employment; from uterine disorders, from excessive childbearing and nursing, from venereal excesses, from excessive muscular or mental exertion, from hæmorrhages and sweatings, &c. An instructed medical eye will at once see that endless phases of such congestion and exhaustion may obtain; and upon accurate measurement of these must depend the temperature of the water to be used in this bath, and the duration of it. In ordinary cases the water may be cold, and the application may continue for from two to six minutes. In some cases of greater delicacy, the water should be at 60°, and the period of its application about three minutes. In still more sensitive and dilapidated persons it may be necessary to apply water at 80° to 100°, for one, two, or three minutes, previous to employing a colder temperature immediately afterwards; the shock of stimulation is in this way broken, and the patient is very gradually inured to the coldest and most tonic temperatures. With precautions of this kind, the spinal wash becomes one of the most useful detailed applications of hydrotherapeia, so great and so numerous are the sympathies of the spinal marrow with the other organs of the body, both internal and external, and so much, therefore, does it become a point upon which those organs converge their irritations, and from which irritations are in return vividly radiated. Hence there is scarcely a state of multiform indigestion, of constipation of bowels or of kidneys, of internal spasm and flatulence, of spasmodic breathing, of nervous palpitation of the heart, of hysterical depression or excitement, of confusion and inaptitude of brain, or of tremor of limbs, to which it is not beneficially applicable. It is a kind of miniature of the falling douche; and when that potent stimulant cannot be obtained, a long spinal wash forms the best substitute for it. Sometimes the spinal washing is confined to the lower half of the spinal column, when the pelvic organs are those upon which it is desired specially to operate, or when the upper half of the spine is so exquisitely sensitive

as to cause spasmodic action of the respiratory or vocal muscles, giddiness, throbbing of head or heart, &c., when strongly stimulated. In such instances the lower half of the spine may be first sponged with cold water, and then the upper half with water from 15° to 30° of higher temperature.

The manner of applying the spinal wash is this:—The patient sits on the edge of a sitz bath or large tub in which is the water to be used; an attendant then pours a half gallon or a gallon jug of the water down the spine, emptying it as it descends, continuing this incessantly during the prescribed time. Sometimes a large sponge is used instead of the jug, but it is not, on the whole, so appropriate as the jug.

Cold Foot Baths.—This simple process has been an especial object of dread or derision to the practitioners of the ordinary medication; of dread to those who are learned but not experienced, of derision to those who are neither one nor the other. Yet its medical effect is most decided when it is tried and observed. The foot is supplied with nervous tissues to an extent and with a complexity only to be equalled, among the external organs, by the hand; and its nerves are derived directly from the lower portion of the spinal cord, which also supplies all the pelvic viscera with nerves. In administering a foot bath, there is first the shock of the water's temperature applied, and this shock is promulgated along the nerves of the legs to the spine, and thence to the contents of the pelvis and belly; next there is the repetition of this shock and stimulation of the nerves by the prolonged friction; and finally, there is the reaction of blood from above towards the foot so rubbed. But besides this, the termination of the spinal cord in the brain gives this process the faculty of acting upon the circulation of the latter through the former. With this anatomical and physiological arrangement clearly before the mind, it will not be difficult to understand how it is that foot baths act in congested and nervous conditions of the womb, the bladder, the flatulent bowels and stomach, in indigestion, in nervous palpitation of the heart, in sanguineous as well as in nervous headaches, giddiness, cold in the head, &c.—in all which conditions of disorder, experience has largely proved this remedy to be most efficient. They who *dread* it have in their view only the effects of cold wet feet, without friction or exercise to produce reaction of blood and warmth. They who *deride* it must be totally ignorant of the nervo-sympathetic connections which that highly sensitive limb, the foot, has with the nervous centres; yet some of them must have limped from the acuteness of a corn or a tight shoe. Not unfrequently a cold foot bath, given within two hours after a full meal, has produced vomiting, and it constantly causes wind in the stomach or the bowels to be immediately and forcibly ejected. It will cause a partially paralyzed bladder to act, a spasmodic womb to be calm, or a constipated womb to secrete, a nervous cough to cease, a stuffed catarrhal nose to open, and a fierce headache to dissipate; nay more, gloom and hypochondriacal depression of mind to be exchanged for lightness and contentment. The temperature of the foot bath must depend upon the sensitiveness and reactive power of the patient, and on his ability for brisk exercise after it. It is often necessary to commence with friction with damp

towels only, or with water at 70° or 80°, which should be gradually lowered. It should always be recollected that reaction of blood and nervous current towards the feet is the final object of the process, and both the temperature of the water and the duration of the friction in it must be accommodated to this end. In this way it is that water at 80° produces as complete reaction in a bloodless and nerveless patient, as water at 50° does in a full-blooded person; but as the blood and nerve increase, so should the temperature of the water decrease, even to the ice temperature, which produces the fiercest reaction of all. It is often desirable, although not essential, to aid the reaction in question by irritating the skin with mustard, flour, or salt, in the water.

The process of the foot bath is to place the feet in about four inches of water, and to rub them vigorously with the hand under the water for a space of time varying from three to fifteen minutes, and subsequently drying them with considerable friction for three or four minutes.

The Sweating Process.—All the cold processes hitherto described and dwelt upon have the effect of rousing the interior organs to reactive energy by the shock of a temperature much lower than that of the skin. But it constantly happens that the internal organs are so enfeebled by reason of the oppression of their functions by long-continued and very great stagnation of blood in their tissues, that it is impossible for the practitioner to rely upon the power of the oppressed organ to react upon the cold shock from without; and if such reaction does not take place, the organ only becomes more congested, in consequence of the additional quantity of blood thus driven upon its tissue; or, which is very frequent also in prolonged chronic disease, the diminution and impoverishment of the blood and of the nervous power is such as to deprive the internal organs of all reactive power: for however small may be the quantity of blood in the entire body, there is the greater tendency for it to accumulate out of all proportion in the interior organs, in order that life may at least be sustained *there* by the vital fluid. Now, in either of these cases the sweating process becomes necessary; that is to say, the blood which cannot be sent to the surface by the process of reaction, must be *drawn*, as it were, by the action of great heat applied to the surface. In doing this the excitation of the circulation is very great—the pulse usually rises from 70 or 80 beats in the minute to 100 or 115, evidencing the rousing of the organism under this hot stimulation. The brain circulation of course partakes of this, and for a short time before the outbreak of sweat there is tightness and throbbing in the head with, occasionally, giddiness; all which dissipates so soon as the skin bursts into perspiration, and to obviate which it is well to apply a cold wet towel over the head, and to keep it cool during the whole process. The time necessary for effecting perspiration varies from ten to forty minutes, and it is by no means the most full-blooded persons who are the swiftest to perspire; on the contrary, if there has been excessive alcoholic stimulation, with congested liver and bloated external tissues, the sweat is mostly slow to come; whilst a person emaciated by anxiety, watching, or any other source of nervous irritation, usually bursts into sweat in five or ten

minutes. Much depends upon constitutional peculiarity of circulation—the slow and phlegmatic responding less speedily than the vivid and active. In order to aid the elimination of sweat, it is often desirable to immerse the feet in six or eight inches of hot water, and to sip a good quantity of cold water during the process. The air of the room should be kept pure by the opening of a window more or less; faintness is then less likely to accompany it, against which contingency, as well as for the administration of water for beverage, it is better that an attendant should remain in the room. The duration of the actual sweating varies from five to fifteen minutes, according to the facility with which the patient bears the process, and the special aim with which it has been ordered. If the object is simply to bring a large quantity of blood to the surface, and so to relieve the interior organs, the appearance of the sweat will be sufficient evidence of this having been effected; and five minutes, or even less, of the actual secreting act will suffice. But if, in addition to this, it be intended to purge the blood vitiated by medicinal poisons, by gout and rheumatic degenerations, the quantity of sweat elicited becomes important, and it should be allowed to flow ten, twelve, or fifteen minutes, or even longer, if the head gives no sign of weariness; and the same applies when the process is given for chronic and dry skin disease. The time from which to date the sweating is when the skin is perfectly moist or running down, not when it has only a glutinous feel; and it is not necessary to await the appearance of sweat upon the face. It is necessary to remark this, since the patient alone can state the condition of the skin under the blankets by which he is covered.

But the sweating process does not consist of the extraction of secretion from the skin only. The blood drawn in large quantities to the surface not only relieves the interior organs from sanguineous oppression, but also presents in the skin an amount of nervous energy and of heat which enables it to react upon the ablation which constitutes the second part of the process; and in this manner the skin gradually acquires the power of reacting even upon very low temperatures. Time after time, oftentimes day after day, the cutaneous bloodvessels are distended with blood, and so become more and more easily able to resist external temperature by reacting on it. Accordingly, after the sweating has continued for the prescribed time, either a wet-sheet rubbing, or a general bath at a temperature varying from 70° to cold, is essential to the completion of the sweating process. Here the same rule obtains as has been already announced in treating of these last-named processes: the temperature of the bath must be accommodated to the organic power of the patient, measured by the pulse, the nutritive and nervous energy, the past and present history of the case. Were the patient merely to be wiped dry after the sweating, the skin would be more sensitive than before, and would, moreover, be covered with, perhaps, morbid secretion. Now, the bath which follows upon the sweating should be always at a lower temperature than the skin in that state, else there will be the same sensitiveness as if only drying had been practised. Beginning, in very difficult cases, at 80°, the water should be steadily decreased

in temperature every few days, and the colour, warmth, and absence of shivering of the skin subsequently be narrowly watched, so as to lose no time in arriving safely at the lowest temperature; for then begins the forcible and undoubted curative action of the sweating process. That process is unquestionably a *disturbing* process; it stirs up the whole interior, and introduces tumultuous effort in the organs thereof to throw off either blood which is oppressing them or blood which is poisoning them, or both. The repetition of this tumult at length begins to worry, as it were, the brain, the nerves of the heart, or the nerves of the stomach, and sleeplessness and headache, or palpitation of the heart, or nausea or vomiting, announce this. The plan then is to intermit the process for one or more days, according to the intensity of the above symptoms, and to take the long sitz bath, foot bath, cold fomentation, or other soothing process, recommencing the lamp sweat so soon as the excessive tumult has subsided. But a close observer and experienced medical eye may detect the signs of such tumult long before it has reached the distressing point alluded to, and will suspend the sweating in order to avoid it. By these means, a patient with obstinate internal congestion, or whose blood has been poisoned with mercury, iodine, and all kinds of aperient drugs, or is infected with gouty materials, may be brought into a state of critical relief without hazarding the integrity of functions of the nervous or circulating centres.

In order to facilitate the action of the lamp sweat, it is for the most part better to precede it, for more or less period of time, by packing, fomentations, warm baths, and all methods the end of which is to reduce the irritability of the brain, nerves, heart, and all the internal organs, so that when the lamp comes to excite the latter to the effort to throw off their congestion, they may make such effort with the smallest amount of irritation to themselves, and to the body generally. And, in fact, the great majority of chronic diseases require that nervous and circulating irritation should be subdued previous to the application of the disturbing and curative measures. Furthermore, the packing and cognate means tend to prepare the skin for the sweating process. It rarely happens that the treatment of a case can be judiciously commenced with the lamp sweat.

From the above it will be plain that the sweating process is not applicable to febrile conditions of the body. A very common but a very decided error of those who do not understand water treatment is, that at the commencement of an acute catarrh it is only necessary to produce sweating by the lamp in order to disperse the cold; whereas that process would unquestionably increase the headache, throbbing, feverishness, and languor of that malady. But suppose that, in consequence of bad management and repeated relapses, the acute has passed into the chronic stage of catarrh, wherein all the mucous membranes have lost their febrile activity, and have become atonic and congested, then the sweating process is strongly indicated, and will be found useful. The same applies to the chronic congestion of any other organ, and notably of the brain, liver, and womb; the lamp sweat will be

found useful when the febrile symptoms have all disappeared, but not sooner. Headache, giddiness, nausea, faintness, and universal throbbings will indicate the inappropriateness of the sweating arising from this cause. When the sweating is employed for long-standing rheumatism and thickening of the joints, and for various skin diseases, the head symptoms should be watched; for in these maladies the lamp may be employed for a much longer time than in other diseases without rousing the secretory activity of the mucous membranes in any of their extent, but the long-continued action of the process occasionally and suddenly tells unfavourably on the brain circulation, and irritation of the brain, or of the spinal cord, or of both, is all at once exhibited. This caution is addressed to those who believe that because the remedy is only being applied for an external malady, it can in no way interfere with internal organs, forgetting that almost all the nerves of the skin take their origin in the spinal cord, itself a prolongation of the brain, and are vehemently stimulated by the alternate heat and cold of the process in question.

It has been already stated that the lamp sweat is a necessary mode of relieving congested interior organs when the bloodlessness and exhausted nervous power of the body is such as to prevent the stimulation of cold which requires reactive energy—in cases of atrophy, for instance. But so soon as by aid of the lamp sweat the skin is acquiring a fulness of blood circulation and an energy of nerve current, the stimulation of the cold processes should be added to and intermingled with the stimulation of heat; for an active circulation obtained by reaction is always more permanent than that produced by attraction. The same combination of stimulating applications should also be practised when, with sufficient blood, it is desired to induce *critical* action, to purge the blood generally in some particular organ. For this reason it is that so many obstinate chronic diseases require that the treatment which began with slight and subduing processes, should terminate with powerful and perturbing measures, such as the falling douche and lamp sweat in combination.

Cold Water Compress.—This is a local and continuous packing, effected by placing a four or five-fold towelling, wrung out of cold water, on the skin, and covering it with flannel alone, or with flannel having oiled silk or mackintosh web underneath, immediately over the wet towel. The region to which this is most universally applied is the belly, especially the upper half of it, over the stomach proper, the liver, and the large plexus of nerves underneath them. But it is used in all local irritations and inflammations, particularly over joints and cutaneous eruptions. The effect of the compress is directly soothing; but if it remains in the hot condition for a long time over a region, it is apt to induce irritation rather than soothing. This is eminently shown when the compress over the upper stomach is allowed to remain for many hours after becoming hot: it causes gnawing and sinking in the stomach, and thence may produce headache, palpitation, &c., all which dissipate so soon as the towelling is wrung afresh out of cold water. It is plain from this that the soothing effect

of compresses is due to the reaction upon the cold on the surface, and that when no further reaction is possible by virtue of the equalization of heat, the latter begins to prove a stimulant, and in time arouses irritation in the very parts which it was intended to soothe. The compress over the chest or belly, therefore, should be refreshed every three hours or so, if it becomes hot in one hour. Those to joints and the skin may remain longer, as they do not involve such important parts; but they too should be refreshed frequently. The quality of the dry covering has to do with this question. If flannel only be used, the wet towelling heats, and soon begins to dry by evaporation; but if impervious tissue, such as mackintosh, be used, the heat, having no exit by evaporation, is much greater in degree and more irritating in action. The best arrangement is to have flannel only, and to wet the compress every three hours; but the majority of chronic patients take to the more convenient plan of wearing mackintosh and changing the compress less frequently. In acute diseases, however, no mackintosh should be used; the compress should be covered with flannel, and changed every hour or two, sometimes more frequently still.

The above processes include all that can scientifically be called the hydrotherapeutic treatment. Their application, to greater or lesser extent, with more or less frequency or intermission, must be regulated by the medical tact of the practitioner. The ignorance of the invalid world, which delights in fussy activity, and has the desire to be ever doing *something*, especially if that something fits with their fears or love of comfort, has caused the introduction, by some pretenders to medical skill, though having no pretence to medical status, of a number of minute and absurd processes, which can have no effect save to amuse and abuse the patient. After this fashion one hand is rubbed in warm water, the other in cold; one foot is gravely rubbed in a tepid bath for four minutes, whilst the other is rubbed for only three minutes; a pint of water is poured slowly over the crown of the head from the forehead backwards, &c., &c. A book is published which is filled with absurdities and dishonesties of this kind, the processes being numbered from one to two hundred and sixty. It is needless to say that the favour given to such a burlesque of medical treatment is given by the same persons, and for the same reason that faith is given to unknown drugs, to which lying effects are audaciously attributed by their promulgators.

Water Drinking.—The processes above enumerated exhibit hydrotherapeia in its application to the exterior membrane of the body. But an important part in that treatment is played by the application of water to the interior membrane of the body, in other words, by the drinking of cold water. Priessnitz laid great stress upon this, and instructed his patients, almost without discrimination of cases, to swallow as much water as they could; and instances are numerous in the history of his practice in which patients drank from twenty to thirty tumblers per diem. A better appreciation of the philosophy of water treatment has led to a considerable modification of this practice, and to a classification of conditions in which much or little water drinking is desirable. As a general rule (and it is impossible

here to enter into details), one or two tumblers of water after each external process suffices in all cases where the morbid phenomena are dependent upon irregular nervous and circulating function alone, and where there is reason, from the previous history, to suppose that no vitiation of the blood has taken place. But in the numerous cases in which internal chronic derangement has existed so long as to have inevitably led to vitiation of the quality of the blood—in those equally numerous cases where the blood has been deteriorated by the actual absorption, during years, of all kinds of drugs, and especially of mercury, iodine, and other mineral poisons, and in the obstinate congestion of certain solid organs, the liver, the spleen, and the mesenteric glands—large doses of water are indicated, varying from six to fifteen or sixteen tumblers per diem. The reasons for this different treatment by water drinking are obvious enough. Whenever a temperature much colder than that of the skin is applied to that surface, the blood is first of all driven upon the internal mucous membrane, and some degree of dryness thereof is the result, as all persons experience in the throat and mouth immediately after a cold bath. To obviate this interior feverishness thus engendered a tumbler of water is taken, and when it is followed by exercise, it promotes the reaction from the interior, which is looked for as a desideratum. When interior organs are obstinately congested, the aim of water drinking is vehemently to stimulate the nerves of the abdominal organs, so that they may arouse the gorged and torpid bloodvessels of those organs, and enable them to throw off their oppressive blood: the quantity of water for this purpose is necessarily large, and its temperature should be very cold. When the same large doses of cold water are taken in cases of poisoned and vitiated blood, an additional aim involved in them is so to alter the animal chemistry going on within the body, and to augment the excretions, that by reason of excessive micturition and sweating the old blood may be gradually excreted, whilst the better appetite and digestion, which is the result of the cold water applied to the stomach, are forming a better elaborated blood to supply it. There is little doubt that water, when absorbed into the circulating blood, acts within the body as it is well known to act out of it, namely, to increase the rapidity of chemical changes; and thus it is that it aids those alterations in the character of the blood, which eventually purify and renovate it, and render it fit for the nutrition of the tissues; the old vitiated blood is abolished by the same measure which augments the formation of the new blood. With these indications the practitioner will be enabled to direct the patient as to the quantity of water which is to be drunk. But there is one point upon which his watch must be kept. The stimulation of the nerves of the stomach afforded by large quantities of cold water, and the absorption of the water into the circulating blood have, from both causes, the effect of sooner or later exciting the circulation and the sensitiveness of the brain and spine; and headache, giddiness, sleeplessness, and, more than all, great irritability of temper, show that, however necessary the continuance of the water for the purposes of the blood may be, its large

absorption must be for a time diminished or suspended, until the nervous excitement subsides. It is related that not a few of the patients at Gräfenberg became apoplectic or insane from this reckless imbibition of cold water.

Rationale of Hydrotherapeutic Treatment.—
